Round the back of the valve-shaft (Fig. 3) a bed of cement-concrete was placed, and the puddle relaid to the top of the embankment. On the 21st of September, 1881, water was again admitted to the reservoir, and a depth of 12 feet 6 inches was obtained, more not being procurable that season. On the 2d of April, 1882, the filling of the reservoir was recommenced, and by the 26th of the same month the water reached a depth of 14 feet when a fresh leak was discovered. A hole was now sunk perpendicularly over the culvert near to the puddle core, and it was found that a crack $1\frac{1}{2}$ inches wide extended almost perpendicularly 20 feet down the puddle core, and appeared to traverse across it completely. This crack seemed to have been caused through shrinkage of the puddle over the culvert, the clay being of a very inferior and sandy quality.

When the culvert was reached, a space was discovered between the brick-work and the original ground which had been filled up with puddle. The space was now found to have developed through the puddle-core to a height of between 12 and 18 inches, and was at once filled up. Water was again admitted to the reservoir until a depth of 27 feet was reached, when another leak commenced; a portion of the puddle at the valve-shaft was again removed, and it was discovered that the masonry had been so badly constructed, that streams of water were pouring through the joints, disintegrating and dissolving the puddle.

The damage having been repaired, the water reached a depth of 35 feet; but it was considered advisable to lower it to 31 feet, and at this depth it remained for a period of three weeks. At midnight on the 23d of August the night watchman reported a serious leak, but this stopped almost immediately. It was, however, deemed necessary to lower the water in the reservoir as speedily as possible, and bags full of clay were kept ready near the valve-shaft for effecting repairs in case of any hole showing itself. All went well, the water lowering at a good speed, when on Sunday morning, the 27th of August, 1882, a serious leak

material thus excavated forming the embankment, which is of enormous proportions, the northern embankment being over 100 feet wide at the top. The bottom of the reservoir was stated to be puddled for a depth of two feet; the author, however, could not discern any difference between the natural ground and the so-called puddle. The slopes were also supposed to be overlaid by one foot of puddle protected by a layer of pitching eight inches thick; but the above remarks will also apply to this puddle. Along the centre of the embankment a puddle-trench had been made, which only extended to about two feet below the bottom of the reservoir; if, therefore, downward percolation took place in the floor of the reservoir, there was nothing to hinder the water from getting away. The author caused the pitching to be stripped for a width of fifty feet at what appeared to be rather a suspicious place, but found that, with the exception of the bank having slightly settled in certain places, there was no indication either in it, or in the solid ground below, of any water having passed through. It appeared, therefore, that any leakage from the reservoir would probably have arisen from the water passing underneath the puddle-trench. As the greater part of the clay to be obtained in the neighborhood was of too sandy a nature to make the reservoir water-tight, and lining the reservoir entirely with stone would have been too expensive, the author determined to cover the bottom and sides with concrete to a height of thirty feet from the floor, thus keeping the lining entirely in the solid. The floor was accordingly excavated to a depth of two feet, and was recovered in the following manner: A bed of one foot of six to one concrete was deposited over the floor, and covered with a layer of cement-mortar in the proportion of one part cement to one part sand; this in its turn was covered with eleven inches of six to one concrete. The floor, and for ten to twelve feet up the sides, was formed in this manner; and from this point up to a height of thirty feet from the floor, all the sides were covered by a layer of concrete eighteen inches thick. The cement used for concrete was brought from England, and

PLAN OF MOLTENO RESERVOIR

again broke into the culvert, and gradually increased to such an extent as to carry away the filling-in round the culvert. The water thus obtained an unobstructed passage to the valve-house, at the north-east toe of the embankment, and down to the city, where it flooded several streets. With great difficulty the flow was checked at the side of the shaft, and a depth of 20 feet of water still being retained in the reservoir, it was gradually consumed for the supply of the city, the whole being exhausted by the 10th of July, 1883. Comparatively little damage was caused by the rush of water through the streets, and it may be looked upon as fortunate that the whole body of water in the reservoir did not force its way into the city. It will be seen from Fig. 3 that the leak commenced at a considerable height above the culvert, passing through the puddle-core; and it is evident that the space between the outlet-culvert and the ground excavated for its construction, not having been properly filled in, had caused the settling of the puddle-core and the subsequent cracks. This space having been reached by the water would enlarge very rapidly, owing to the inferior quality of the material used for filling it up. The author finds that the tunnel was constructed by first driving a heading through the undisturbed ground under the embankment, which was much too large, then building the tunnel, after which the surrounding space was filled in by laborers, whose work, there being hardly any supervision, was very imperfectly executed.

The bursting of the reservoir along the line of culvert was not, however, the only source of complaint. It was stated by persons in the neighborhood that the whole reservoir leaked, and was doing damage to property below; they therefore sought to restrain the Town Council from again attempting to repair or fill the reservoir.

The repairs were finally placed in the hands of the author. It appeared to him that the subject should be divided under two heads. First, what to do with the reservoir proper, and secondly, what alteration to make in the culvert. The excavation for the reservoir was nowhere less than twenty-five feet deep into the solid ground, the

was all tested. The breaking-test was 650 pounds on $2\frac{1}{4}$ square inches; many of the briquettes, after being in water for a week, did not break under a strain of 1,000 pounds on the square inch.

Up to a height of 30 feet, as it was all in solid, no movement could be anticipated through the settling of material behind the concrete; but above this point, where the made embankment commenced, although it had been standing for three years, some slight settlement might be expected. For this reason the author considered it inadvisable to cover the upper portion of the embankment with such unyielding material as concrete, and therefore removed the pitching, and 2 feet of the embankment underneath, keeping the slope as before. The most clayey and suitable portion of this was selected for puddle, and a bed 1 foot thick was relaid, after having been cross-cut and watered slightly. On the top of this a layer of gravel was deposited and thoroughly punned, and over this a layer of pitching one foot deep, well blended with gravel.

The earth-work of the embankment outside the puddle-core is of a most untrustworthy nature, and the heavy tropical rains excavate holes in the sides and top which enlarge with great rapidity. The author therefore gave a slope at the top with a fall of 3 feet towards the outside, and built a drain near the top of the outside slope leading to two rough waste-water courses at the east and west ends of the northern embankment, and covered the whole of the summit of the embankment with a layer of 6 inches of gravel, which the rain soon consolidated. A wall 4 feet 6 inches high was also built round the east, west and north sides of the embankment, at the top of the inside slope.

The culvert was then uncovered to the top of the crown of the arch to ascertain the extent of the damage, and it was found that a space about 2 feet high existed along the outside of the arch. As the sides had suffered no damage, the trench was refilled with earth in 6-inch layers, which were each carefully punned as the work proceeded.

The tunnel from the angle to the former valve-house, with the pipes therein, was retained, a fresh portion extending 100 feet further being added, and terminating in a new

valve-house. The culvert was extended because the pipes in the old valve-house were 17 feet underground, and in case of fracture could only be approached with great difficulty.

From the angle to the inside of the reservoir the old culvert and the old valve-shaft were entirely removed, and a new culvert, encased in concrete, was built from the angle to the inside toe of the embankment, where it terminates in a brick tower.

Across the puddle-trench a large portion on each side of the reach was excavated, and a concrete wall, of an average thickness of 5 feet at the bottom and 3 feet at the top, was built to top-water level. A second cross concrete wall, about 4 feet thick, was constructed near the spot where the old valve-shaft stood; this extends to 30 feet from the floor of the reservoir, the concrete at the sides there resting on it, being well toothed on both sides into the embankment. All the earth-work on the inside and outside of the breach, which did not appear thoroughly solid, was cut down, and the earth-work carried to the top of the embankment simultaneously with the concrete walls in layers of 6 inches, each layer being properly punned.

At present water is supplied to this and the lower reservoirs by a number of springs on the side of Table Mountain.

The smaller springs fall off rapidly in fine weather. It is surprising what an amount of water is wasted during heavy rain; such an amount of dirt and vegetable matter is then brought down, especially at the commencement of the rainy season, that the water is rendered unfit for storage. Although the rainy season begins in April or May, the springs are never at their strongest until August and September, after which they gradually fall till March.

A number of bore-holes were made on the side of the mountain above the reservoir, varying from 50 to 90 feet in depth, in each of which water was found; but it gradually disappeared. The whole of the cliff debris at the base of Table Mountain resembles a sponge, which is constantly being supplied by water filtered through the sandstone.

The reconstruction of the reservoir was carried out for \$187,000, and it was finished in eighteen months.

SEVENTEENTH ANNUAL REPORT ON THE COLUMBUS WATER-WORKS.

THE treasurer, Mr. Dudley A. Filler, reports the total cost of the works at \$753,064.85. Total receipts for the year from operation of the works, \$94,833.38; operating expenses and repairs, \$26,625.50. There were 393 meters and elevators in use, or a decrease of 56 from last year. The consumers have in these cases abandoned the use of meters rather than pay the cost of repairs.

Mr. A. H. McAlpine, Superintendent and Chief Engineer, reports the estimated population at 80,000, with about 25,000 using the water, there having been 464 new takers during the year. The distributing system consists of 69,100 miles of 4-inch to 24-inch pipe, 555 fire-hydrants, 539 line-valves, 486 elevator and hydrant valves, and 4,531 service connections. Additions for the year were 10,572 feet of pipe and 27 hydrants. There are two Holly quadruplex condensing engines of 4,000,000 gallons daily capacity each, and one Gaskill horizontal compound condensing engine of 10,000,000 capacity. Coal consumed for the year, 7,837,925 pounds. Average duty of the engines, based on an evaporation of ten to one, was 87,003,700. Daily average of water pumped, 5,208,107 gallons. Cost per million gallons, \$7.09, being a decrease from the previous year of 31.8 per cent. The greatest daily average pumped was 6,190,468 gallons during the month of January; the lowest was for November and was 4,712,434. The average water-pressure is 35 pounds, and the fire-pressure 115 pounds, the latter having been maintained for 67 hours without any accident.

The appendix contains the by-laws and regulations, a useful table showing the discharge from various sized ferrules at the average pressure, and the weights and sizes of pipes required.

Also a scale of meter-rates, with the maximum supply for various payments. Also a table of water-rates.

A NEW Board of Health will be organized in Morristown, N. J., as the present board is not legally constituted under the State law passed last spring.

NOTES ON ENGINEERING WORKS AT BOMBAY.

MR. KILLINGWORTH HEDGES, M. I. C. E., contributes some interesting notes on the engineering works at Bombay, India, to the *Engineer*, from which we abstract the following:

The Prince's Dock is being greatly extended, and is the most important work in the city; also there are several extensive engineering works in active progress in the neighborhood of Bombay. Of these, the new water-supply of the city, which is anticipated to deliver thirty-three million gallons daily, in addition to the present supply, is the most important, the waters having to be led in conduits and pipes a distance of 53½ miles from the artificial lake which is now being formed. Through the courtesy of the executive engineer, Mr. W. Clarke, the writer was given every facility of inspecting the whole of the work.

The magnificence of the new terminus of the Great Indian Peninsula Railway impresses the visitor to Bombay. In outward appearance there is some resemblance to the Caledonian station at Glasgow, except that the area covered by the Great Indian Peninsular terminus and offices is much larger, and after passing through the magnificent booking hall, with its vaulted roof and marble columns, one is surprised to find the platforms of the station cramped as to accommodation, and covered by a very low roof with very deficient lighting. The railway carriages are designed for coolness, having double roofs and sides; the gauge of the line, five feet six inches, admits of considerable interior room and ample accommodation for five persons to lie full length at night, the top berths folding up during the daytime; there is also a lavatory for each carriage, with an ample supply of water, and in some cases a shower-bath. In fact, the long journeys which passengers have to take in India necessitate sleeping accommodation to be afforded without extra charge. On the Great Indian Peninsula Railway there are three classes, a proportional charge per mile being made, so that first-class is 12 pies, or about 1¼d. per mile; twice the amount of second, and four times the price of third-class; the exact fare is always marked on the ticket, and for the third-class both in English and Persian figures; the latter class is doubtless the paying factor of Indian railways. Unimpeded with luggage, the natives throng at every station, taking up positions on the platforms hours before the departure of the train, and complacently squatting until the arrival of the next train, if, as it frequently happens, there is no room.

The workshops of the Great Indian Peninsular Company, are situated at Parell, a small station about five miles out of Bombay.

Repair work is only carried on in the locomotive department, but the carriages and wagons are constructed at Parell. Teak wood is exclusively used for the bodies, the frames being made of iron, which is also extensively employed for the covered goods wagons, the sides and roof being made of iron plates fastened to a wooden frame. There are 3,000 men in the locomotive and 2,000 in the carriage department, who are all natives, the European staff consisting of fifty who are foremen or draughtsmen. It is curious to see how the various trades are exclusively taken up by certain classes; thus the fitters are all Parsees, the carpenters mostly Jews, the tinsmiths Mohometans, and the copper-smiths and blacksmiths are all Hindoos. Indian railway traveling is slow, a great deal of time being lost at stations by reason of the apparent helplessness of the natives in getting in and out of the carriages; there is much, however, to interest the engineer. At one station we see large quantities of old pot sleepers discarded for the more practical Vignoles rail; at another, in order to save a turntable, two lines run off so as to form an inverted A, the locomotive running up one siding and back on to the main line by the other. A temporary road has been made from Atgaon station to Tansa; a continuous string of country bullock carts being met during the seven miles of drive; these carts are owned by the contractors for the dam works, Messrs. Glover & Co., and fetch the lime from the station. The method of driving the bullocks is primitive, and simply consists of screwing their tails, the driver sitting on the pole with a tail in each hand. The animals seem little worse for this treatment, but many die in the dry season, therefore bullock transport is not so cheap as is generally imagined.

The limit of what is to be the artificial lake is marked out with stones painted red; these are worshiped by the natives, whether on account of the red color of the engineer's fetish I cannot say; but we were treated to the singular spectacle of a native praying and making offerings to what appeared to be a very ordinary bench mark. The area, at present occupied by a teak forest, which is to be flooded, is eight square miles; the catchment area, from which the rainfall will be collected, is over 52 square miles, from which every source of contamination will be removed. The water will be impounded by means of a dam across the River Tansa, which will be built to a height of 109 feet above the river-bed. The total length of the dam at top when finished will be 8,700 feet; and excavations for the foundations are being rapidly completed along the whole length. The ashlar work will be bonded on to the solid rock, which is only met with at a depth varying from 20 feet to 50 feet, on account of the trap formation, which, cropping up to the surface in places, is full of fissures. Some 4,000 men and women are at work on these foundations, the men either excavating the earth or drilling holes for blasting, the women taking away the spoil in baskets. With the exception of the tramway which brings stone from a quarry that has been opened up down the

river, all the labor of removing the spoil is performed by women, who are simply provided with shallow baskets which they balance on their heads. This method is nearly always practiced in India, and in the opinion of many engineers is far more efficient than barrows, trollies, or carts, and has the great merit of enabling any number of coolies to be set to work on a given spot, where it is desirable to move a large quantity of spoil. For instance, on the Jhansi section of the Indian Midland Railway I found Mr. Walter Merivale, the executive engineer, had concentrated about 700 men, women, and children in a small area consisting of a depression and a slightly rising ground which was immediately required for a store yard. The method adopted was as follows: Fifty or sixty men were told off with picks and large hoes to dig up the earth and fill the baskets. At the place where the earth was to be deposited stood six chuprassies, or foremen, with bags of tin tickets, and close to the work a responsible clerk sat with an assistant, having spread before him 50 rupees' worth of money in copper and small silver. The coolies, or cowrie wallahs, as they are termed, carry a basket-load of earth on their heads, and as they deposit it receive one or more tickets, according to the load and the fullness of their basket; half empty baskets are thrown down and not paid for, but they are generally full. As soon as a coolie has a few coppers' worth of tickets, he or she goes to the table and changes them for their value in money, and this constitutes the popularity of the system, as they can come and go as they like, and they can work fast or slow. The value of the tickets is arranged so that the coolies can earn about twenty per cent. more than their usual pay, which is for men about 3 annas to 4 annas a day, women 2½ annas, and children 1 anna to 1½ anna; this increase pays well, as a good deal more than a usual day's work is obtained. The excavation of the foundations of the dam necessitates a great deal of blasting, which is done by native labor. The powder is all made quite close to the work in a most primitive manner by a native who employs women to grind it in the ordinary flour mills which are found in every native hut. The proportion is as follows: Nitre, 2; sulphur, 2; and charcoal, 3, to which, after the paste has been dried and ground, a small portion of sharp sand is added. The cost on the ground is 16s. 6d. per cwt., and the efficiency is said to be equal to the ordinary imported powder, which would come to very much more.

In this and many other districts in India, limestone in the shape of small nodules, known as "kunkah," is found in large quantities; from it most excellent lime is made which is moderately hydraulic. The burning of the lime and the preparation of mortar is carried out at Tansa on a large scale. The extensive character of the Tansa works may be gathered from the amount of the contract for the dam alone, which is 30 lakhs of rupees, or, roughly, £300,000, the contract time for finishing the work being six years, but it will be probably finished in less. Payment to the contractor is made monthly on the engineer's certificate, and 50 per cent. advance is made on the value of materials on the ground. Of the total payment, 10 per cent. is deducted and reserved for contingencies, and a lakh of rupees has been deposited on commencement.

THE fourteenth annual report of the Board of Health of the city of New Haven for 1886 estimates the population at 80,000, which gives a death-rate of 17.4 per 1,000, 1,392 deaths having been reported. Dr. C. A. Lindsley, the Health Officer, embodies in his report a brief essay on filth and the diseases connected with its presence, and remarks that "the intelligence of tenants on sanitary questions is exerting an influence more potent than all the authority conferred on boards of health to bring landlords to a right way of thinking."

"If the people demand sanitary houses the landlords will provide such for them; but the time to make the demand is before they take a lease. It is a very injudicious method to move into a house first and then come to the Board of Health with complaints that the sinks and basins are untrapped or that an overflowing cesspool is running into the cellar. It is very much better to let the unwholesome houses stand empty." He goes on to say: "The plain statement of the situation is this. New Haven is not a model city from a sanitary point of view. The relation of your board to its sanitary condition is not just what it should be, and not what it is generally supposed to be. While in public estimation you are held more or less responsible for good sanitation within its limits, yet from a legal outlook you have very little authority to remove the evils which disturb the public health or to force the observance of those fundamental laws which you know so well are essential to its preservation. Your functions are limited to discovering the local influences which produce disease, enforcing the abatement of a few of those most offensive to the popular sense, and by slow and tedious stages instructing the people in the importance of the subject."

This applies well to most cities and to most boards of health in this country, nor can it well be otherwise under our form of Government.

The total expenses of the board for the year were \$7,119.81.

PAVEMENTS AND STREET RAILROADS.
No. XII.

(Continued from page 323.)

WOOD PAVEMENT IN THE METROPOLIS.*

THE expansion of wood is a question demanding consideration in carrying out such works. In unprepared blocks this is specially necessary, and in proportion to the width of the street so is it desirable to leave a space next the footways, varying from one inch to two inches in width. The actual condition of the wood and the state of the atmosphere at the time of laying exercise a material influence upon the width of the margins thus left. Another mode is by omitting to grout the channels for a week or longer period after the other portions have been completed; and another by paving nearly up to the kerb, and afterwards taking out the nearest course so soon as expansion sets up. In any case, it is necessary to temporarily fill up the margin with sand or other suitable material, which can be raked out from time to time until expansion ceases, which generally occurs in the course of twelve to eighteen months from completion. In the Chelsea works it was then found desirable to rake out the temporary filling, and where any space was left, to fill in with cement grout, the surface being carefully pointed in cement. This work effectually renders the channels impervious to water, and tends to prevent premature decay, and was executed at a cost equal to 0.86d. per square yard of pavement.

It frequently happens that, notwithstanding those provisions, and whether the blocks are plain or dipped, the outer portions of the footways become displaced during the period of expansion, but subsequent to the above-named period wood pavement generally maintains a fairly constant state. The author has never observed any contraction in wood pavement except during the severe frost in January, 1881, at which time, when 22° of frost were registered, several rather alarming cracks in a longitudinal direction appeared in the Sloane Street pavement, at places where the wood was especially exposed to the severity of the weather. Immediately the frost terminated the cracks appeared to close up naturally, and the pavement assumed its former sound condition.

This plain system of pavement was laid in Sloane Street and King's Road in 1879, and upon closely observing the effect of nearly five years' traffic upon it, the result is eminently satisfactory. The plain type of pavement had previously been adopted by Messrs. Mowlem & Co. in several parts of the metropolis, with the exception that their joint was wider and was formed of lime grout, and that their form and manner of studding were different, and the author ventures to assert that it comprises all the essentials of a sound pavement; a quiet and smooth surface for vehicles being provided, and the pavement being sufficiently close-jointed to insure a safe foothold for horses. Experience proves that the cement joint is reliable, that it adheres to the blocks, effectually resists wet, and does not unduly wear down below the surface of the wood, and thereby allow dirt to accumulate in the joints, neither does it permit displacement of the blocks; the author therefore feels that he may justly pronounce it successful, and claim for it another advantage as compared with the mastic-joint—viz., the absence of the annoyances which are created by asphalt kettles in streets during the execution of the works. Upon inspecting the numerous openings which have been made for gas and water services or drainage-works, the actual condition of the wood and foundation has invariably proved satisfactory; the surface of the concrete is hard and dry, the joints are sound, and the blocks as a rule present a fairly good surface, and are not found to contain an excessive amount of moisture.

The prime cost of the pavement in King's Road and Sloane Street amounted to 10s. 6d. per square yard, and the only repairs which have been found necessary consisted in the removal of some defective blocks during the past twelve months. The blocks were originally 5.87 inches deep, whereas their present average depth measures 5.22 inches in King's Road and 5.60 inches in Sloane Street. The probable life of the block may be taken at seven years for King's Road and eight years for Sloane Street. The annual vertical wear of wood is equal to 0.144 inch in King's Road and 0.065 inch in Sloane Street, and if reduced to a traffic standard of 750 tons per yard width daily, the following results are obtained—viz.:

King's Road.....	0.196 inch.
Sloane Street.....	0.175 "

Several other systems of pavement were laid in King's Road at the same time for the purpose of practically testing their respective merits. In one instance a layer of metallic lava asphalt one-half inch in thickness was laid upon the concrete foundation, the blocks being laid and jointed as already described. Opposite the Royal Military Asylum wall creosoted blocks were adopted, one length being formed with a semi-mastic joint—namely, the lower half bituminous mastic and the upper half lime grout—the other being entirely jointed with grout composed of lime and sand. The section of pitch-pine blocks previously described was also laid at this part, the joint consisting of Portland cement grout. The author has carefully examined the various experimental sections of pavement, the cost of which, together with the ascertained wear and other particulars, are as follows—viz.:

(a) *Plain deal blocks on layer of Asphalt*—The cost amounted to 12s. 4d. per square yard; the present depth of the blocks is 5¼ inches; the foundation is in a perfect

condition, and the blocks are fairly good. The estimated life of the pavement is seven years, the average annual wear being 0.139 inch.

(b) *Creosoted blocks, with mastic joint*—The cost was 14s. 2d. per square yard; the present depth of the blocks is 5¼ inches, and the foundation is perfectly sound. The lime grout part of the joint has perished and almost crumbled away, consequently a good deal of dirt has been pressed into the part above the bituminous portion, and the blocks came up very easily. The pavement may last for eight years, the average annual wear being 0.139 inch.

(c) *Creosoted blocks, lime joint*—The cost was 11s. 10d. per square yard; the blocks are 5¾ inches deep, and in a fairly good condition. The failure of the lime joint may possibly arise from a chemical action of the creosote; but it certainly has perished, and causes dirt to accumulate. The blocks will probably last eight years, the average annual wear being 0.111 inch.

(d) *Pitch-pine blocks*—This section costs 11s. 8d. per yard, and the present depth of the blocks is 5¾ inches. The foundation is dry and sound, and the cement-joint perfectly satisfactory. The repairs to the blocks have been very slight, and they will probably last eight or nine years, the average annual wear being 0.055 inch only.

If reduced to a traffic standard of 750 tons per yard width per day, the figures are: Pavement (a) 0.209 inch; (b) 0.240 inch; (c) 0.204 inch; (d) 0.088 inch.

Practically, the plain pitch-pine pavement is cheaper than yellow deal, and the ascertained vertical wear promises admirable results; but it does not appear that either of the other modes is attended with any particular advantage.

Other Pavements—In 1876, the Improved Wood Pavement Co. laid a short section in King's Road, near the Vestry Hall, in which planks were laid upon the concrete foundation, and "dipped" pitch-pine blocks were used; but in consequence of numerous complaints of the disagreeable rumbling and jarring noise which the rapid passage of vehicles over it caused, it was taken up and relaid without the boards after a period of seventeen months, an additional length being at the same time laid with "dipped" deal blocks. These pavements were subsequently particularly unfortunate, inasmuch as the "mastic" joint caused the surface to become uneven and bumpy, and rendered it necessary to execute frequent repairs, a considerable portion being relaid in 1882. Upon examination it transpired that the substance which formed the "mastic" joint had partially melted, presumably from the heat of the sun, and that the material had got underneath the blocks and forced them upwards. In November, 1883, the pitch-pine section was finally taken up, and the other portions were again repaired by the company for the same cause. Like results may be seen in other districts where a similar joint has been adopted.

The ascertained average depth of the pitch-pine blocks at the time of removal was 5¾ inches, the average annual wear during a period of seven years being 0.089 inch, or if reduced to the traffic standard, 0.119 inch. The deal blocks were measured and found to be 5 inches deep, the ascertained annual wear being 0.157 inch, and according to the traffic standard, 0.195 inch. With additional repairs, the latter may last another year, making their life seven years. The author further objects to this form of joint, because the melted asphalt adheres so tightly to the surface of the concrete that it is necessary to chip it off before new blocks can be laid, which process destroys the smooth surface of the concrete so considerably, that it necessitates a bedding of sand before new blocks can be properly laid. Further, the bitumen adheres so tightly to the blocks that to well cleanse them for reuse not only involves much labor, but is injurious to them, especially if they have borne two or three years' traffic, and the fibres have begun to spread. In the latter case they are not only unsound, but are also unfit to make neat or satisfactory work.

The Improved Wood Pavement Co., whose experience is probably greater than that of any other company, have laid their system in many of the leading streets, among which may be mentioned King William Street, Bishopsgate Street, Queen Victoria Street, Whitehall, Bond Street, Park Lane, and Old Brompton Road. In all instances where the patented system had originally been adopted, advantage was taken to modify and simplify it whenever it became necessary to renew the blocks. The company have entirely discontinued to lay a plank in the foundation, and now limit their system to the use of "dipped" blocks, laid with a semi-mastic joint upon a concrete foundation. For the purpose of comparison, the weight of the traffic being known, the following streets are referred to:

Ludgate Hill—Originally laid on boards in November, 1873, at a cost of 18s. per square yard. The terms of maintenance are, one year free, and fifteen years 1s. 6d. per square yard per annum. The blocks and plank foundation were taken up and new blocks laid on a concrete foundation and single board in 1877. The pavement was again taken up and laid with new blocks on the new principle—namely, without the intervening boards—in February, 1884, when the blocks were found to average 3 inches deep, their actual life being seven years. The author saw this pavement taken up, and was surprised to find how easily it was removed; the mastic joint had evidently lost its strength, and the result possibly points to the fact that its efficient durability does not extend beyond a limited period. The annual average wear of the last-mentioned wood was 0.428 inch, and if reduced to the traffic standard it was equal to 0.259 inch.

Aldersgate Street—Cost 15s. per square yard in September, 1874; the maintenance terms being two years free, and fifteen years at 1s. per square yard per annum. It was taken up and relaid on a concrete foundation in 1877, the blocks being merely reversed, and laid on lime mortar. In March, 1884, the blocks were renewed, the average depth then being 3½ inches; but in some parts the wood was only 2 inches thick. The annual wear was equal to 0.264 inch, and the actual life of many of the blocks was no less than nine and a half years. The blocks recently laid are 5 inches deep.

Northumberland Avenue—Paved in February, 1876, at a cost of 15s. per square yard, exclusive of the concrete foundation, which had been laid by the Metropolitan Board of Works. It is maintained by the company at a rate of 13s. per square yard for fifteen years. Baltic pine blocks, 6 inches deep, were laid on planks, and the approximate wear is 0.125 inch per annum. The surface is uneven, and shows considerable wear at the upper end, but its life will probably be nine years.

Leadenhall Street—In July, 1876, the western end was paved at a cost of 12s. 3d. per square yard, with two years' free maintenance, and fifteen years at 1s. per square yard per annum. The pavement was taken up, and 5-inch blocks laid in 1879, without the planks. The wood is considerably worn, and the surface is bumpy, probably from the mastic joint. The approximate wear of the wood is 0.200 inch per annum, which, reduced to the traffic standard, is equal to 0.186 inch per annum.

Piccadilly—An area of over 16,000 square yards was laid in April, 1876. In 1880 nearly two-thirds were renewed, and the boards taken out, the remainder done in February, 1882. Further repairs have been executed, and the surface shows considerable signs of wear. The author has been unable to obtain information as to the depth of blocks.

Knightsbridge—The portion east of Albert Gate was paved in April, 1878, the blocks being laid upon a single plank, and concrete foundation. The part west of Wilton Crescent was taken up in September, 1883, when the plank was removed, consequently the actual life of the wood was nearly five and a half years. The daily traffic is about 780 tons per yard width, or 250,000 tons per annum.

Parliament Street was paved in December, 1880, at a cost of 13s. 8d. per square yard, and the company maintained it for three years at an additional charge of 4d. per square yard per annum. The foundation is Portland cement concrete, 12 inches thick. The annual wear of the wood is 0.154 inch, and if reduced to the standard is equal to 0.104 inch.

Oxford Street, opposite Hereford Gardens, was originally laid on boards in November, 1874, at a cost of 16s. per square yard, with maintenance two years free and thirteen years 1s. per square yard per annum. In May, 1877, the boards were removed and new blocks laid, but they are now in a very bad condition, and are about to be taken up. Their life will have been seven years.

Henson's patent pavement has been practically tested, having been laid in Fleet Street, Oxford Street, Brompton Road, Euston Road, Uxbridge Road, and elsewhere. The theoretical principles of this system, which consists of a cement-concrete foundation, plain deal blocks on a felt bed, a close felt joint, and a dressing or grouting of boiling or prepared tar, and the merits of the felt bed and joint, were fully described in Mr. Howarth's paper, and the following particulars of ascertained wear may be useful in considering its merits.

Oxford Street, Princes Street to Marylebone Lane, was laid in November, 1875, at a cost of 16s. 6d. per square yard on existing concrete. The company offered to maintain it for fifteen years for 10s. per square yard, but the Marylebone Vestry arranged to do this work by their own staff. The pavement was repaired in 1879 and following years, the blocks being entirely renewed in September, 1883. Yellow deal blocks, 5 inches deep, were originally laid, and when taken up averaged 5½ inches thick, their actual life being 7.84 years. The annual average wear of wood was therefore 0.191 inch, which, if reduced to the traffic standard already described, gives 0.120 inch.

Oxford Street, Duke Street to Portman Street, was paved in October, 1876, at a cost of 14s. per square yard on existing concrete, the maintenance terms offered being 10s. per square yard for a period of twelve years. Six-inch blocks were laid, and they were repaired in 1880, 1881, 1882, and 1883, their present average depth being 3.60 inches. The surface of the wood is considerably worn, but upon recently inspecting an opening in the pavement, the foundation and joints were in excellent condition. The probable life of the blocks is eight years. The average annual wear of the wood is equal to 0.323 inch, and as reduced to the traffic standard 0.255 inch.

Oxford Street, Hereford Gardens to Edgware Road, was paved in December, 1875, at a cost of 16s. 6d. per square yard on existing concrete. The blocks were repaired each year from 1879 to July, 1883, when they were renewed. They were originally 6 inches deep, were worn to an average depth of 3½ inches, and had a life of 7.58 years. The probable life of the existing blocks is eight years. The annual average wear of the former wood was 0.329 inch, and as reduced to the traffic standard was equal to 0.250 inch.

Brompton Road—The eastern half was paved in December, 1878, at a cost of 12s. 9d. per square yard, with a free guarantee of three years. Since then frequent repairs have been executed by the Kensington Vestry. Six-inch blocks were laid, the present average depth of which is 4.94 inches. The surface is worn in places, and is bumpy and somewhat unpleasant to drive over. It is very dirty at the joints.

*A paper by George Henry Stayton, Assoc. M. Inst. C. E., and printed in the Minutes of the Proceedings.

The probable life of the wood is six and a half years, the average annual wear being 0.184 inch, or according to the traffic standard 0.236 inch.

Fleet Street.—The western half was laid in September, 1877, at a cost of 16s. per square yard, the maintenance charge being 17s. per square yard for nineteen years. It has been repaired from time to time since 1881, and is now considerably worn and uneven. The probable life of the wood is seven years. The average annual wear of the wood is 0.269 inch, which according to the traffic standard is equal to 0.173 inch.

Leadenhall Street.—In August, 1876, the eastern half was paved at 18s. 6d. per square yard, the maintenance being two years free and seventeen years' annual maintenance at 8d. per square yard. The paving has been repaired on several occasions since 1880, and parts are now in a very bad condition, the wood having quite worn through in places. The paving is to be renewed this spring, after a duration of seven and a half years; and, taking the average depth of the blocks at 4 inches, the annual wear is equal to 0.264 inch, which reduced to the traffic standard is 0.198 inch.

Euston Road, Cleveland Street to Gower Street, was paved in November, 1880, at a cost of 11s. 6d. per square yard, with three years' free and twelve years' annual maintenance at 8d. per square yard. The pavement is in fairly good condition, only trifling repairs having been carried out, notwithstanding that the weight of the traffic per yard width is equal to 700 tons per day.

It must be apparent to any one who has carefully noticed Henson's pavement that there is a minimum of jarring, and consequently a very steady motion in driving over it when it is in good condition; yet experience seems to prove that after a few years' wear it is not in reality cleaner or less dusty than a plain close-jointed pavement, and a reference to Table V. in the appendix clearly shows that in durability it does not take the highest place.

The system adopted by the Asphaltic Wood Pavement Company consists in laying a ½-inch layer of asphalt upon the concrete foundation, upon which "dipped" blocks were placed, the lower part of the joint being of asphalt and the upper of Portland cement grout. This pavement has been laid in Fleet Street and other parts of the city, The Strand, Oxford Street, High Holborn, Hatton Garden, Brompton Road and elsewhere.

(TO BE CONTINUED.)

FALL MEETING OF NEW ENGLAND WATER-WORKS ASSOCIATION.

THE fall meeting of the New England Water-Works Association will occur on Wednesday, September 14, and will include an excursion to Lake Winnepesaukee.

In compliance with numerous requests the Executive Committee announces that one of the prominent features of this excursion will be the entertainment of the ladies who accompany members of the association, and members are urged to see to it that a large number of ladies are present.

Members and guests of the association will meet at the station of the Boston and Maine Railroad, Haymarket Square, Boston, on Wednesday, September 14, in season for train leaving at 8:30 A. M. The party will arrive at Alton Bay at 11:50 A. M. and at this point will take steamer "Mt. Washington" for Centre Harbor, touching at Wolfborough and Long Island. Returning the association will leave Centre Harbor at 1:45 P. M., Alton Bay at 4:45 P. M. Arrive in Boston at 8 P. M. The party will thus have a sail of four hours in which to enjoy the picturesque scenery of the lake region. Tickets, which will include dinner served on the boat, will be \$4 each, and may be obtained at the Boston station on the day of the excursion. Members are requested to occupy the special cars which will be assigned for the party. The tickets will allow those desiring it to remain at Centre Harbor or Wolfborough and return at a later day. If any considerable number desire to remain over at either Centre Harbor or Wolfborough, special hotel arrangements can probably be made. Those intending to remain should communicate at once with the Secretary. That ample provision may be made for the comfort of all it is highly important that the Secretary should know the exact number who will participate. Will you please mail a prompt reply.

A short business meeting will be held on the steamer, at which time all new applications for membership will be considered. Edwin Darling is President and R. C. P. Coggeshall, New Bedford, Mass., is Secretary.

THE Louisville *Courier-Journal* of the 29th ult. gives a lengthy account of the setting of some large columns in the new Government building in course of erection there. These are monoliths, 23 feet high, 2 feet 10 inches in diameter at the base, and 2 feet 4 inches at the top. The weight was about ten tons, and the stones were set by the use of a "breast" derrick. We notice the article to call attention to two points—the great size of the "lewis" used in lifting (about 17 inches long by 2 inches thick), and the method taken to insure contact between the lewis and the hole cut to receive it.

As to the length, we can hardly conceive it necessary. In sound granite a well-fitted lewis ¾-inch thick and 4 or 4½ inches long would certainly have lifted the columns. Of course in softer stone a greater length would be desirable. At the rear of the New York Anchorage of the East River Bridge a lewis, 12 inches long by 1½ inches thick, in limestone, bore several times this strain, and masses of

limestone of 10 to 11 tons were repeatedly hoisted by the 4½-inch lewis.

The method pursued at Louisville to insure contact was to pour sand into the hole after inserting the lewis, and is worthy of mention as a simple and effective expedient.

THE EFFECT OF SEA-WATER ON CONCRETE.

THOSE who use Portland cement concrete will be interested in the discovery to which the *Scotsman* drew attention recently. It appears that the Aberdeen harbor seaworks have suffered considerably. The concrete blocks have been seriously affected by the sea, and the authorities have been rather puzzled to account for its destructive action. Very great reliance has been hitherto placed by engineers and architects on Portland cement concrete; but this good opinion has been somewhat shaken, if all that we hear of certain hydraulic works can be substantiated. We take our information from recent accounts that have come to us. Indications of failure have been observed for some time in important sea-walls constructed of concrete, and the Aberdeen harbor works, if what we learn is true, confirm the misgivings which are entertained. The action of sea-water on concrete has been suspected of late years; but up to this time a satisfactory explanation of the damage sustained has not been given. Experiments have been recently made by direction of the Aberdeen authorities by Professor Brazier, of Aberdeen University, and Mr. William Smith, the harbor engineer. The decayed concrete has been ascribed to the force of the sea and wind, though the action was chiefly noticeable in the graving-dock in still water. The writer in the *Scotsman* says: "It is the action of the sea-water under pressure in still water that has rendered the nature of the damage in the present instance so conspicuous." The quay walls and breakwater were constructed fifteen years ago, the graving-dock two years ago, and in all these works a disintegration of the surface of the concrete by the chemical action of the salt water has been going on. The entrance walls are said to be built of Portland cement concrete, composed of one measure of cement, two measures of sand, and three measures of stones, with large rubble-stones incorporated in the walls. The wall surface is plastered with Portland cement mortar up to three feet of low water, the mortar being made of one measure of Portland cement and one of sand; the upper part of wall is faced with granite. During the process of emptying the water from the graving-dock, a hydraulic pressure varying with the tides of from 5 to 11 pounds per square inch is put on this concrete skin, the water forcing its way through pores of the skin, producing cracks and saturating the quay walls. The chemical action is hastened in proportion to the exposure, and is increased by the passage of water through the body of concrete. Various injuries are reported—e. g., the joints of the ashlar facing have opened in parts, owing to the loosening of the concrete surface beneath. The engineer consulted Professor Brazier. Test briquettes were prepared for analysis with a view of discovering the proportion of magnesia contained, and which was supposed to account for the damage. The Portland cement, it was found, had not contained more than one-half per cent. of magnesia, whereas the decayed concretes showed an increase in the quantity of hydrate of magnesia of 13½, 15, 22, and in one case as much as 40 per cent. This could only have been derived from the sea-water. Another deleterious substance found in the decayed concrete was carbonate of lime, which could hardly be traced in the Portland cement of the same standard. The concrete taken from the south breakwater showed it to have undergone a similar chemical change. The outer quay wall surrounding the side of the graving-dock were built of plastic concrete or Portland cement concrete, mixed in the usual way with a certain quantity of water, and allowed to set two to four hours, then broken up and deposited within frames under water in skips with opening bottoms, the concrete being left *in situ* in the frame. These walls do not show the same action or decay. Portions have been rebuilt with Roman cement concrete under water, but no decay has been noticed in them, and the only protection to the Portland cement concrete from the chemical action of the sea is apparently a non-porous lining or facing of stone-work.

Every care is said to have been taken in the concrete used; the cement had withstood the mechanical tests, and the concrete had set hard. The same failure of Portland cement concrete was noticed by Mr. Harrison Hayter, Vice-President of the Institution of Civil Engineers, two years ago. After a time the concrete expanded, vertical cracks of the material lifted some inches, and the surface cracked and flaked off. In every case a white "cream-like" substance was observed in the concrete, which Mr. Hayter had analyzed and was found to contain 80 per cent. of magnesia hydrate, consisting of about two-thirds magnesia oxide and one-third water. In every case of decayed concrete magnesia was present. Professor Brazier's experiments are confirmatory of the fact that these deposits of decayed cements contain magnesia, but he believes the substance comes from the action of the sea-water, and is not present in the Portland cement, as Mr. Hayter thought to be the case. We cannot enter into the details of the experiments made by Professor Brazier on the cement blocks, and the results he obtained by digesting some of the cement in sea-water, from which it appears that the amount of lime and magnesia contained in the sea-water in its original state is accounted for after the cement has been separated from the water, there being a gain of lime and a loss of magnesia amounting to nearly all the magnesia contained in the sea-water. Hence the same authority concludes that Portland cement cannot resist the action of sea-water.—*The Builder*.

ANNUAL REPORT OF THE BOARD OF PUBLIC WORKS OF ST. PAUL, MINN.

THIS report is based on those of L. W. Rundlett, Chief Engineer, and his assistants, A. Munster and George L. Wilson.

The board states that work done far exceeds that of any former year in the city's history, nearly equaling that of any two previous years.

One hundred and eleven sections of streets have been graded, with a total length of 42½ miles—an average cost of \$16,576.79 per mile, and a cost per foot of \$1.44.

Sections of seven streets and one alley have been paved, comprising 2½ miles.

Thirty thousand three hundred and fifty-one square yards of asphalt pavement have been laid at a cost of \$3.26, including 20 cents for grading and \$1 per lineal foot for curb.

Twenty-three thousand and seventy yards of cedar-block pavement have been laid at a cost per square yard (including cost of curb) of \$1.88.

Seventeen thousand four hundred and seventy square yards of pine-block pavement, with granite curb, at a cost of \$1.68. This pavement has been on steep grades where, in wet or frosty weather, it is stated that cedar blocks would have been too slippery. The specification require white pine blocks six inches deep, four inches wide, set on 2-inch plank foundations, and with rows separated three-quarters of an inch, the spaces being filled with paving cement and gravel.

The asphalt paving was laid by the Warren-Scharff Asphalt Paving Company on a concrete foundation under Washington specifications under a ten years' guarantee of all needed repairs without cost to the city, and a further guarantee for ten years at a price of one cent per square foot per year, fifteen per cent. of the contract price being withheld for a term of ten years.

Eleven miles of sewers have been constructed at a cost of \$269,117, three-fifths of the cost being assessed on property benefited.

Fifty-nine miles of wood sidewalk, costing \$85,831, and nine-tenths of a mile of stone sidewalk, costing \$23,064, were laid.

A large amount of sidewalks were also laid by individuals.

There were 35.64 miles of streets and alleys opened, widened, or extended, at a cost of \$585,413.

Grades were changed on twenty-five streets, at a cost of \$67,690.

The total cost of all improvements made during the year was \$2,009,806.

The Engineer's pay-rolls for the year amounted to \$36,000, and the pay of inspectors was \$20,200.

The board say truly: "These figures clearly demonstrate the fact that St. Paul is pushing its public improvements quite as rapidly as prudence and an economical administration of its affairs will justify."

A number of recommendations are made, of which we notice two:

First.—The suggestion that the letting of contracts may be authorized for the paving of two or more streets under one contract (or that two or more improvements may be made under one contract), where convenience or economy shall be subserved by so doing.

Second.—That as a measure of relief to property-holders, the time of redemption of property sold to pay assessments shall be extended to five years, the interest charges reduced, and that payments by installments be authorized.

The City Engineer makes the statement that "the value of abutting property is very much increased by reducing the grades on important avenues to a maximum of five per cent., even at considerable expense." In Washington a 4½ per cent. maximum has been recommended.

On the subject of telegraph wires he recommends that all poles in the business district be 60 feet high, the two top cross-arms to be reserved for city use free of charge; all poles to be absolutely under control of the city, with power to remove any wires after 24 hours' notice should the lines not be kept in proper order.

There are now 1,003 street monuments located and recorded, of which two hundred were set last year.

The total rainfall for the year was 21.89 inches, the average for 16 years being 27.81. The extremes of the thermometer in 16 years have been -39, December 25, 1879, and +100, July 1, 1883. The cost per mile for street sweeping has been \$12.77 in the upper district and \$7.97 in the lower, the streets being mostly 40 feet wide.

The Robert Street iron bridge, 1,541 feet long, with roadway 32 feet wide, and two sidewalks each 10 feet wide, has been completed at a cost for substructure of \$126,998.98; superstructure, \$191,512.01; total, \$318,510.99.

FALL OF AN ELEVATOR IN A DRY-GOODS HOUSE IN NEW YORK.

On Thursday, the 18th of August, at about 7:45 A. M., an elevator in the dry-goods house of G. Sidenberg & Company, at 49 Mercer Street, New York City, fell, having on board about thirteen persons; all but

FIG. 1.

the man who operated the car being female operatives going to the work-rooms in the upper stories. One woman was instantly killed and the man who operated the car was seriously, if not mortally, injured, by having his spine dislocated, while all the other passengers sustained injury to the ankles and more or less serious shock to the system. The elevator had reached a height estimated at forty feet when it was stopped at a landing. Simultaneously with the working of the hand-ropes the car began to fall with all on board, and though it did not obtain a velocity equal to a fall through a height of forty feet, it struck the ground with sufficient force to cause the injuries above

mentioned. The elevator is of a type of Otis Bros. & Co.'s make, now considered old as compared with hydraulic elevators, and this one was fifteen years in use. Still there are many of the same kind in use in hotels and stores as passenger-elevators (though this one was principally used as a freight-elevator), as it is of the type of steam passenger-elevators that was considered first-class before the introduction of the hydraulic elevator.

The defect was one that human foresight could scarcely guard against, as a cursory and even minute examination might not detect it unless it was suspected. We, therefore, have gone to the trouble and expense of illustrating the elevator entire, and we also show in detail the defective pinion-wheel, the splitting of which caused the accident, in order that architects, engineers, and inspectors of elevator plants may be thoroughly conversant with the cause of this accident, and thus be the better able to guard against a similar accident in the future; as any spur gear machine, no matter by whom made, is subject to the same danger.

Figure 1 shows the engine on the basement floor. It is a double stationary cylinder machine, with belt and idler which gives motion to the shaft on which the broken pinion was keyed. The pinion engages the winding drum on the inside, the principal reason for an inside gear being to prevent the cables from getting cut by the gears, as often happened with older machines. A second winding drum is used at the top of the house as shown, and the two drums are connected by a cable—in some cases by double cables. When the elevator car is down, the cable from the lower drum is wound on the upper drum and the cable of the upper drum is unwound by the car. When the engine starts it winds the lower drum, which in turn winds the upper drum by unwinding the cables F, F therefrom, at the same time the upper drum is winding up the car and the cables G G.

The safety apparatus are two-fold. First, there are the usual ratchet and dogs on the guide-posts. These save the car if the cables break between the upper drum and the car, but are not sufficient to catch the car if the cables break between the upper drum or sheave and the lower winding drum, as the pull of the unbroken part of the cables will not let the springs throw the catches into place; hence the second or upper drum. The second safety-device, therefore, is on the upper drum in the form of a safety-brake that is thrown into use by the centrifugal action of governor balls, shown at the top in Fig. 1. This governor

FIG. 2.

(B) is set for some particular speed, say 200 feet per minute, and should the engine run away, or the cables between the two drums break, or an accident such as occurred August 18 happen, the governor is supposed to trip the trigger-catch at *b* and throw on the brake D. In this case it is claimed the brake did trip, but that it did not hold. Whether the brake did or did not trip is not clear, but it is evident that the car came down with too much speed; though the presumption is the brake did catch, but with the load carried it was not sufficient to check the car after it had fallen some distance. It probably, however, prevented a more serious disaster, as had the car struck the ground after falling forty feet the theoretical speed would be fifty feet per second or 3,000 feet per minute. The unwinding of the cables from the drums, however, and other friction would have lessened this, but in any case the speed would have been enormous and sufficient to have killed nearly all in the car.

Figure 2 shows the pinion-wheel that split, with the line of fracture. It was of cast iron, 5 inches long and 6½ inches in diameter, with 11 teeth. The teeth were 4 inches long, as a stiffening flange ran around one edge of them. The nut was ⅞ of an inch thick in its thickest part and ⅜ in the key-way. It is supposed that it was keyed too tightly and split, as oil had worked into the fracture at A. The pinion was cast into shape and not milled out, which is impracticable in such small wheels with an end flange.

We presume "cast" cast steel would make a safer pinion than cast iron for such places, and even brass would be safer, though it would not wear so long.

It is but justice to the manufacturers to state that the elevator was fifteen years in use and that it had never been inspected by them, and as it was not registered at the Building Department as a passenger-elevator, it was not inspected by the Department Inspector, which inspection is made about every three months in the case of passenger-elevators in New York City.

E. G. LOVE, Ph.D., Gas Examiner.

AN interesting gas case was recently decided in one of the London Police Courts. It appears that the Wandsworth and Putney Gas Co. brought action against a consumer to recover something over £12 for gas alleged to have been consumed from Christmas, 1886, to Lady Day, 1887. During the four preceding quarters the largest bill was £7 16s., and the consumer tendered £8 in payment of the bill in question, which, however, was refused by the company. The meter was found to be correct by a Government inspector. The defendant and his family all swore that, if anything, less gas had been burned than during the quarter preceding. The Justice, however, ordered the defendant to pay £8, but awarded him £8 costs. It is not likely the company will drop the matter here.

MR. G. R. HISLOP, in a paper read before the North British Association of Gas Managers on the "Gratuitous Supply of Burners by Gas Companies and Corporations," maintained that it was the "duty of every gas company and corporation to bridge over all deficiencies in science or general information on the part of their consumers, and supply them with the means of economically consuming the gas they deliver. In every department of trade or commercial enterprise, the producer is careful to show up to his patrons the special features, capabilities, or superiority, it may be, of his over all other competitive productions, in order that with such knowledge the value of the products may be enhanced." His plan is to determine the pressure throughout a given district and to supply burners capable of passing the required amount under the varying pressures, account being taken of the candle-power of the gas, and a suitable allowance made for loss of pressure after entering the consumer's premises.

A NEW YORK CITY syndicate, of which J. R. Bothwell is a member, is negotiating for the purchase of the works of the Halifax, N. S., Gas Company. The directors of the company favor the sale.

LEARNING A TRADE.

THE *Jewelers' Journal* argues—we think wisely—in favor of boys learning a trade in the shop. It says:

"When a boy has once gained the practical knowledge which every boy of the least ability will naturally acquire in a shop he is fitted to convert the knowledge which a college or university course offers him into useful wisdom."

The greatest fallacy of modern educationalists is that a boy can better be taught to do something by theory than he can learn to do something by practice. This has never proved true, and there is no reason to believe that it ever will. There are thousands of college graduates in this country to-day whose prospects of getting a living are extremely precarious, because they know nothing except what they were taught at college. On the other hand, there are a great many who have had their ideas broadened by a college course, and are correspondingly benefited thereby. Simple as the whole matter is, there are many who cannot be made to see it, and they are helped along sometimes, in their blindness, by those who ought to know better. The idea that a college course alone will fit a man to get a decent living is as fallacious as the idea that such a course cannot be made to help him in getting along in the world. The best advice, in our opinion, that can be given boys in this respect is: Do not depend upon what you may acquire at some institution of learning to get you comfortably through the world. The failures will be a hundred to one. On the contrary, do not despise what you may learn at schools and colleges. This will be a mistake, though not so fatal as the one first named.—*American Machinist.*

THE International Association of Plumbers, Gas-Fitters, and Steam-Fitters of the United States and Canada will hold its next meeting, September 5, at Fraternity Hall in Milwaukee.

REVISION OF THE NEW YORK PLUMBING RULES.

WE print below the revision of the plumbing rules, which has just been completed and adopted by the New York Board of Health. We have indicated by italics those portions in which the principal changes have been made. The important ones are: The definition of the time within which, after the filing of plans, work must be begun or new plans be filed. Under the regulation now adopted, if work is not begun within six months, the approval of the board must be again obtained. This provision is, no doubt, a safeguard against a fraudulent change of plan after it has passed the board, which would be resorted to by some skin builders. Another change is in the more stringent regulation of the laying of the house-sewer from the street to the house-wall. The board now reserves the right to compel the laying of an extra heavy iron pipe in cases where the ground is filled in, in place of ordinary iron pipe. School-sinks or privy-sinks of the sort now used are not recognized. The use of modified forms will be passed upon as occasion arises. When there are no sewers it is permitted to use a water-tight cesspool. As a concession to the views of the President of the Board of Health, the rules now explicitly give to the board authority to omit the trap from the main house-drain. Further than this Mr. Bayles and the Board of Health did not care to go. The location of the air-inlet from inside the trap is now more strictly defined. Perhaps the most important change is found in the requirement that "extra heavy" iron pipe must be used in all cases. Hitherto, the board has only required its use in certain conditions. Tarring of iron pipe is prohibited.

These are the changes of widest bearing, but if the italicized portions of the rules be studied it will be found that there are many amendments in the direction of a more stringent enforcement of the purport of the Plumbing Law of 1881. Five years' experience and the support of the plumbers and the community have emboldened the board to go several steps beyond the earlier rules.

The rules were formulated after obtaining the views of a Special Committee of the New York Master Plumbers' Association.

RULES AND REGULATIONS.

I.

THE REGISTRATION OF PLUMBERS.

Rule 1. Every plumber engaged in business in the city of New York shall appear in person at the Health Department, No. 301 Mott Street, and register his name and address, pursuant to the provisions of chapter 450, Laws of 1881, upon the forms prescribed by the Health Department.

Rule 2. It shall be the duty of every plumber to give immediate notice of any change in residence or place of business, for the correction of the Register.

Rule 3. The list of registered plumbers shall be published in January of each year.

II.

OF PLUMBING.

The law requires that the plumbing and drainage of all buildings, public and private, shall be executed in accordance with plans and specifications previously approved in writing by the Board of Health; and that suitable drawings and descriptions of the said plumbing and drainage shall, in each case, be submitted and placed on file in the Health Department.

Plans of plumbing work filed with this Board for approval shall state within what time the work therein described will be begun. If it is not begun under approved plans within the time thereon specified, such plans must again be presented to the Board for reconsideration. Plans are approved upon the condition that such approval expires by its own limitation within six months from date of permit, unless work under it is then in progress.

Drawings and descriptions of the plumbing and drainage of buildings erected prior to the passage of the act of 1881 may be placed on file in the Health Department.

Blank specifications for plumbing and drainage will be furnished to architects and others, on application at this office.

As the law requires that the plumbing and drainage be executed according to a plan approved by the Board of Health, no part of the work shall be covered or concealed in any way until after it has been examined by an inspector of the Board of Health; and notice must be sent to the board when the work is sufficiently advanced for such inspection.

III.

PLAN OF DRAINAGE AND PLUMBING APPROVED BY THE BOARD OF HEALTH.

The following plan of construction has been approved by the Board of Health. When the work is completed, and before it is covered from view, the board must be notified, that it may send an inspector.

1. All materials must be of good quality and free from defects; the work must be executed in a thorough and workmanlike manner.

2. The arrangement of soil and waste-pipes must be as direct as possible.

3. The drain, soil, and waste pipes and the traps must, if practicable, be exposed to view for ready inspection at all times, and for convenience in repairing. When necessarily placed within partitions or in recesses of walls, soil and waste pipes must be covered with wood-work so fastened with screws as to be readily removed. In no case shall they be absolutely inaccessible unless so placed in accordance with a permit issued by the Board of Health.

4. All interior water-closet compartments in tenement-houses shall be ventilated into air-shafts of not less than three square feet in area.

5. Where there is a sewer in the street every house or building must be separately and independently connected with it. When possible such connection must be made directly in front of the house.

6. Where the ground is made or filled in, the house-sewer, by which is meant the portion of the drain extending from the public sewer to the front wall, must be of extra heavy cast-iron pipe of such diameter as the Board of Health may approve. Such pipes should be laid with the joints properly calked with lead.

7. Where the soil consists of a natural bed of loam, sand, or rock, the house-sewer may be of hard, salt-glazed and cylindrical earthenware pipe, laid on a smooth bottom, free from all projections of rock and with the soil well rammed to prevent any settling of the pipe. Each section must be wetted before applying the cement, and the space between each hub and the small end of the next section must be completely and uniformly filled with the best hydraulic cement. Care must be taken to prevent any cement being forced into the drain to become an obstruction. No tempered-up cement shall be used. A straight-edge must be used inside the pipe, and the different sections must be laid in perfect line on the bottom and sides.

8. Where there is no sewer in the street, and it is necessary to construct a private sewer to connect with a sewer in an adjacent street or avenue, it must be laid outside of the curb, under the roadway of the street on which the houses front, and not through the yards or under the houses.

9. The house-drain must be of iron, with a fall of at least one-quarter inch to the foot.

10. Where water-closets discharge into it, the house-drain must be at least four inches in diameter.

11. It must be securely held in place against the cellar-wall or properly suspended from the cellar ceiling. It can be laid under the cellar floor only when a permit from the Board of Health has been obtained.

12. It must be laid in a straight line, if possible. All changes in direction must be made with curved pipes, and all connections with Y-branch pipes and one-sixteenth or one-eighth bends, if possible.

13. Any house-drain or house-sewer put in and covered without due notice to the Health Department, must be uncovered for inspection at the direction of the inspector. *Old sewers or house-drains can be used for new houses only when found by an Inspector of this Department to conform in all respects to the foregoing regulations governing new sewers and drains.*

14. Unless omitted by permission of the Board of Health, a running or half-S trap must be placed on the house-drain at an accessible point near the front of the house. This trap must be furnished with a hand-hole for convenience in cleaning, the cover of which must be properly fitted and made gas and air tight with some suitable cement properly applied.

15. When the trap described in Section 14 is required in the house-drain, there must be an inlet for fresh air to enter the drain just inside of the trap, of at least four inches in diameter, leading to the outer air and opening at some place shown on the approved plans, not less than ten feet from the nearest window. No cold air-box for a furnace shall be so placed that it can possibly draw air from this inlet-pipe.

16. No brick, sheet-metal, earthenware, or chimney flue shall be used as a sewer-ventilator, nor to ventilate any trap, drain, soil, or waste pipe.

17. Every vertical soil and main waste pipe must be of iron, and where it receives the discharge of fixtures on two or more floors, it must extend at least two feet above the highest part of the roof or coping or light-shaft louvers, and have a diameter above the roof at least one inch greater than that of the pipe proper; but in no case shall it be less than four inches in diameter above the roof. No cap or cowl shall be affixed to the top of such ventilation-pipe, but in tenement-houses a strong wire basket shall be provided, and securely fastened thereto in every case, to cover the mouth of it.

18. Soil, waste, and vent pipes in an extension must be extended above the roof of the main building when otherwise they would open within twenty feet of the windows of the main house or the adjoining house.

19. Horizontal soil and waste pipes are prohibited.

20. The least diameter of soil-pipe permitted is four inches. A vertical waste-pipe into which a line of kitchen-sinks discharges must be at least three inches in diameter if receiving the waste of five or more sinks, and shall have two-inch branches.

21. Where lead pipe is used to connect fixtures with vertical soil or waste pipes, or to connect traps with vertical vent-pipes, it must not be less than one-inch pipe.

22. There shall be no traps on main vertical soil or waste pipes.

23. All iron pipes must be sound, free from holes or cracks, and of the grade known in commerce as extra heavy. The following weights per lineal foot will be accepted as standards:

2 inches,	5 1/4 pounds per lineal foot.
3 "	9 1/2 "
4 "	13 "
5 "	17 "
6 "	20 "
8 "	27 "
10 "	33 1/2 "
12 "	45 "

24. All fittings used in connection with such pipe shall correspond with it in weight and quality. No tar-coated cast-iron pipe shall be used.

25. When required by an inspector from the Board of Health, plumbing-work must be tested with the pepper-mint-test or by other approved methods, such test to be made by the plumber in the presence of the inspector. Defective pipes discovered must be removed and replaced by sound pipes, and all defective joints made tight, and every part of the work in which defects are found be made to conform to these rules and regulations.

26. All joints in iron drain-pipes, soil-pipes, and waste-pipes must be so filled with oakum and lead and hand-calked as to make them gas-tight.

The amount of lead used to a calked joint shall be not less than twelve ounces to each inch diameter of the pipe so connected.

27. All connections of lead with iron pipes must be made with a brass sleeve or ferrule of the same size as the lead pipe, put in the hub of the branch of the iron pipe and calked with lead. The lead pipe must be attached to the ferrule by a wiped or overcast joint.

28. All connections of lead waste and vent pipes shall be made by means of wiped joints.

29. Every water-closet, urinal, sink, basin, wash-tray, bath, and every tub or set of tubs, and hyarant waste-pipe, must be separately and effectively trapped; except where a sink and wash-tubs immediately adjoin each other, in which case the waste-pipe from the tubs may be connected with the inlet side of the sink-trap. In such a case the tub waste-pipe is not required to be separately trapped. Urinal platforms, if connected to drain-pipes, must also be properly trapped.

30. Traps must be placed as near the fixtures as practicable, and in no case shall a trap be more than two feet from the fixture.

31. All waste-pipes from fixtures other than water-closets must be provided at the outlet of such fixtures with strong metallic strainers to exclude from such waste pipes all substances likely to obstruct them.

32. In no case shall the waste from a bath-tub or other fixture be connected with a water-closet trap.

33. Traps must be protected from syphonage, and the waste-pipe leading from them ventilated by a special air-pipe, in no case less than two inches in diameter for water-closet traps and one inch and a half for other traps. Except in private dwellings, the vertical vent pipes for traps of water-closets in buildings more than four stories in height must be at least three inches in diameter, with 2-inch branches to each trap, and for traps of other fixtures not less than two inches in diameter, with branches 1 1/2 inches in diameter, unless the trap is smaller, in which case the diameter of branch vent-pipe must be at least equal to the diameter of the trap. In all cases vertical vent-pipes must be of cast or wrought iron.

34. Vent-pipes must extend two feet above the highest part of the roof or coping, or light-shaft louvers, the extension to be not less than four inches in diameter, to avoid obstruction from frost, except in cases where the use of smaller pipes is permitted by the Board of Health. They may be combined by branching together those which serve several traps. These air-pipes must always have a continuous slope to avoid collecting water by condensation.

35. No trap-vent pipe shall be used as a waste or soil pipe.

36. Overflow-pipes from fixtures must, in each case, be connected on the inlet side of the trap.

37. Every safe under a wash-basin, bath, urinal, water-closet or other fixture must be drained by a special pipe not directly connected with any soil-pipe, waste-pipe, drain or sewer, but discharging into an open sink, upon the cellar floor, or outside of the house. The outlets of such pipes should be covered by flap-valves.

38. The drain-pipe from refrigerators shall not be directly connected with the soil or waste pipe, or with the drain or sewer, or discharge upon the ground; it should discharge into an open and water-supplied sink. Such waste-pipes should be so arranged as to admit of frequent flushing, and should be as short as possible, and disconnected from the refrigerator. In tenement-houses it must be ventilated above the roof. Covering the outlet by means of a flap-valve is recommended.

39. The sediment-pipe from kitchen-boilers must be connected on the inlet-side of the sink-trap.

40. Water-closets must never be placed in an unventilated room or compartment. In every case the compartment must be open to the outer air or be ventilated by means of a shaft or air-duct. All water-closets within the house must be supplied with water from special tanks or cisterns, the water of

which is not used for any other purpose. Interior water-closets must never be supplied directly from the Croton supply-pipes. Except in tenement-houses, a group of closets may be supplied from one tank, but water-closets on different floors are not permitted to be flushed from one tank. In tenement-houses there must be a separate cistern for each water-closet, and one water-closet must be provided for each two families.

41. The overflow-pipes from water-closet cisterns may discharge into an open sink or where its discharge will attract attention and indicate that waste of water is occurring, but not into the soil or waste-pipe, nor into the drain or sewer. When the pressure of the Croton is not sufficient to supply these cisterns adequate pumps must be provided.

42. The valves of cisterns must be so fitted and adjusted as to prevent wasting of water, especially where cisterns are supplied from a tank on the roof.

43. Water-closets, when placed in the yard, must be so arranged as to be conveniently and adequately flushed, and their water-supply pipes and traps must be protected from freezing.

The compartments for such water-closets must be ventilated by means of slatted openings in the doors and roof.

44. No privy-vault or cesspool for sewage will be permitted in any part of the city where water-closets can be connected with a public sewer in the street.

45. Tanks for drinking-water are objectionable, but if indispensable they must never be lined with lead, galvanized iron, or zinc. They should be constructed of iron, or wood lined with tinned or planished copper, or wood alone. The overflow should discharge upon the roof, or be trapped and discharge into an open sink, but never into any soil or waste pipe or water-closet tank, nor into the drain or sewer. Discharge-pipes from such tanks must not deliver into any sewer-connected soil or waste pipe.

46. Rain-water leaders must never be used as soil, waste, or vent pipes; nor shall any soil, waste, or vent pipe be used as a leader.

47. When within the house, the leader must be of cast iron, with leaded joints, or of copper, with soldered joints. When outside of the house and connected with the house-drain it must, if of sheet metal with slip joints, be trapped beneath the ground or just inside of the wall, the trap being arranged so as to prevent freezing. In every case where a leader opens near a window or a light-shaft, it must be properly trapped at its base. The joint between a cast-iron leader and the roof must be made gas and water tight by means of a brass ferrule and lead or copper pipe, properly connected.

48. No steam exhaust, blow-off or drip pipe shall connect with the sewer or with any house-drain, soil-pipe or waste-pipe. Such pipes must discharge into a tank or condenser from which a suitable outlet to the house-sewer may be provided.

49. Cellars should not be connected to the house-drain unless necessary. Dry cesspools should be used where practicable. Mason's traps for yards, cellar and area drains are prohibited.

50. Subsoil drains must be provided when necessary. When used they must be effectively trapped and means provided to maintain a seal.

51. Yards and areas, and open light courts, must always be properly graded, cemented, flagged, or well paved, and properly drained; when the drain is connected with the house-drain it must be effectively trapped. Front area drains must, where practicable, be connected with the house-drain inside of the running trap, if one is used.

52. Cellar and foundation walls must, where possible, be rendered impervious to dampness, and the use of asphaltum or coal-tar pitch in addition to hydraulic cement is recommended for that purpose.

53. In no case will the general privy accommodation of a tenement or lodging house be allowed in the cellar or basement.

54. When there is no sewer in the street, and no way of reaching a sewer on an adjacent street or avenue, by any means provided for in these regulations, privy-vaults and cesspools will be permitted; but in all cases they shall be built and maintained absolutely water-tight. They shall be placed as far as practicable from any well, and so ventilated that no nuisance shall result therefrom.

Correspondence.

All correspondents should send us their names and addresses, not necessarily for publication, but as a guarantee of good faith and because it is often necessary to communicate with them for additional information before printing their communications. Anonymous letters will not be noticed.

A PROBLEM IN HOUSE DRAINAGE.

SCRANTON, PA., August 3, 1887.

SIR: Inclosed I send you a sketch (Fig. 1) of soil and ventilating pipes as are now in place in one of the best buildings in this city. There is a great defect in their operation, and it is proposed to remedy them by making alterations as set forth on sketch.

The dotted lines represent the pipe now in place and discharging into a cesspool about forty or fifty feet from the building. The lines at bottom of sketch represent proposed improvement by discharge into sewer 300 feet distant. One proposition is to commence at A, and putting the trap outside of garden wall, with a pipe from sewer to about two or four feet above ground, with a view of ventilating through rain-water pipe. The air-inlet pipe is shown outside of garden wall.

Another proposition is to begin at B and leave out one trap entirely, and put the other trap inside of garden wall, with a short pipe reaching above the surface of the ground between the trap and residence.

As some change is necessary at once, all parties have agreed to submit the question to you, and we would like to have you answer as soon as possible. We are now making alterations in water-closets, and would be very much pleased if you would give the question your immediate attention. Respectfully yours, F. W. WATSON.

[On the data furnished we should advise placing the trap on house-drain near the house-wall with fresh-air inlet, as is the practice in New York, Boston, and other cities. As the character of house is not stated—i. e., whether with front wall near sidewalk as in New York, or a suburban house with piazzas—we cannot say whether the trap should be placed inside the house with fresh-air inlet from just outside the wall, or whether the trap should be located in an accessible brick vault just outside the house. If there is available room we should prefer the latter plan.

We should place no trap between the house-trap and the sewer, and if the public sewer had manhole ventilation near the point of proposed junction with this 300 feet of private drain, the necessary ventilation of this 300 feet of drain could be secured by connecting a leader pipe with this drain just beyond the main trap in the vault. This suggestion is made on the assumption that the public sewer is kept in reasonably good condition. The leader-pipe should then be of good material and air-tight in its joints, so as to carry the escape above

windows, either of your own house or the adjoining houses. If this cannot be done you will have to trap the leader by having it enter the drain on the house side of the main trap in the vault. Then secure what ventilation for the drain you can by placing a vent-pipe for the 300 feet of drain as near the vault as you can so as to avoid offense—i. e., between it and the junction with the public sewer. If this cannot be done, forego the ventilation of the drain.

Your soil-pipes should extend full size at least through the roof. You will also need a grease-trap to prevent stoppage in the long private drain from grease. You will see illustrated methods of arranging a main trap and fresh-air inlet in a brick vault in "House Drainage and Plumbing Problems," on pages 43, 45, and 47.]

HOW TO MAKE HARD WATER SOFT—COVERING FOR LEAD PIPES UNDERGROUND.

BEAR RIVER, ANNAPOLIS CO., N. S., }
July 29, 1887.

SIR: (1) I have a tank plastered with Portland cement and a brick partition across one end to serve as a filter. The water is hard and very dark colored. Is there any way it can be made soft and clear as spring-water? (2) What is the best covering for lead pipe that is to be buried underground? Respectfully yours, W. W. CLARKE.

[(1) The only method that is practicable by which to soften water on anything of a large scale is what is known as Thomas Clark's method. He was Professor of Chemistry in the University of Aberdeen and patented the method about forty-three years ago.

Buck, in his "Hygiene and Public Health," says: "The process is a strictly chemical one and may be explained as follows: Take fifty-six pounds of pure quicklime and expose it to moist carbonic acid and it will absorb forty-four pounds of the carbonic acid and unite chemically with it, forming 100 pounds of carbonate of lime. This carbonate of lime will not dissolve of itself to any extent in water, but in the presence of carbonic acid there is formed soluble bi-carbonate of lime, and the amount of carbonic acid necessary to convert 100 pounds of carbonate of lime into bi-carbonate is exactly equal to that which has already

combined in the 100 pounds of carbonate." He then says: "Suppose that we have proceeded in this way and have now over 144 pounds of bi-carbonate of lime dissolved in water. If then we slake fifty-six pounds of quicklime and add to the solution, this will combine with the forty-four pounds of extra carbonic acid and form 100 pounds more of carbonate of lime in addition to the original 100 pounds, which, being now robbed of the carbonic acid which kept it in solution, will separate from the solution as a white powder along with the newly-formed carbonate of lime."

"In the case of any given amount of water the amount of lime necessary may be determined by analysis, or it (the lime) may be run in until it is evident from certain simple chemical tests that enough had been added. The lime is used as strong lime-water or milk of lime. After the treatment the water is allowed to settle from twelve to twenty-four hours and drawn off from the sediment. If the water is colored by peaty matter a very appreciable discolorization is effected."

The Newark Filtering Co., the Crocker Filtering Co., the National Water Purifying Co., of this city, and the Albany Steam Trap Co., of Albany, N. Y., claim to have processes for filtering, clarifying, and aerating water for domestic use which can be easily applied to the treatment of any quantity of water with good effect and at moderate expense.

(2) Black asphaltum varnish is about the best paint we know of to apply to pipes before they go in the ground; but do not confound it with black paraffine varnish, as the latter is worthless for this purpose.]

PERSONAL.

SURGEON W. K. VAN REYPEN has been appointed Medical Inspector of the Navy.

A BOARD, consisting of Captain Brown, Medical Inspector Bradley, and Civil Engineer Endicott, has been appointed to prepare a plan for the improvement of the Naval Hospital Grounds at Portsmouth, Va., for which \$50,000 was appropriated by Congress at its last session.

MR. GEORGE A. ELLIS, C. E., was Chief Engineer to the Racine, Wis., Water Construction Company. The works were tested a few days since, and one of the engines named George A. Ellis after him.

DIRECTOR WAGNER and Chief Engineer Park, of the Bureau of Gas, Philadelphia, are making a trip of inspection to the gas-works of several cities to gain additional information to be used in enlarging the Philadelphia works.

DR. EDWARD GERMER, of Erie, Pa., died in that city August 22, aged fifty-six years. Dr. Germer was President of the Pennsylvania State Board of Health under Governor Pattison, and was at his death delegate-elect to the International Sanitary Congress, which meets in Vienna in September.

COLONEL J. B. CLOUGH, Assistant Chief Engineer of the Northern Pacific Railway, died in Helena, Mont., August 22.

ASSISTANT CONSTRUCTOR HOOVER, of the Brooklyn Navy Yard, has been ordered to Washington to take charge of the preparation of plans for one of the new war vessels.

CAPTAIN WALTER L. FISK has been ordered from West Point to Washington for duty in the office of the Chief of Engineers.

JEFFERSON BORDEN, President of the Fall River Iron-Works Company and the Fall River Gas Company, of Rhode Island, died August 22, aged eighty-six years. Mr. Borden had been actively connected with the manufacturing and railroad interests of Fall River since 1821.

REAR ADMIRAL THOMAS T. CRAVEN, U. S. N., died at Charlestown Navy Yard, August 23, aged eighty years. He entered the Navy in 1822 as midshipman, was a captain in 1861, and saw service at the Battle of New Orleans and on the Mississippi. He was made a Rear Admiral in 1866, and was in charge of the Mare Island Navy Yard.

W. G. PROVINES, for nine years City Engineer of Cheyenne, Wyo., has resigned, owing to pressure of private business.

MAJOR DAVID PORTER HEAP, U. S. Engineers, has, at his own request, been released from duty as Engineer Secretary to the Lighthouse Board, and been assigned to duty as Engineer of the Third and Fourth Lighthouse Districts.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITIONS.

HAMILTON, ONT.—Plans and specifications, in competition, are asked for by the Hamilton Coffee Tavern Company. For the best plan a \$100 prize will be given, for the next best a \$50 prize. The plans and specifications are to be the property of the company. The company does not bind itself to adopt any of the plans, but if any are adopted the author may expect to be employed to superintend their execution. Plans will be received up to 15th September next, addressed to Alfred Powis, Secretary, 31 King Street, East, Hamilton, Ont. Each must be marked with some device or motto.

PROPOSALS.

NOTICE TO CONTRACTORS AND BUILDERS.

Sealed proposals will be received at the office of the Superintendent of Public Schools, Birmingham, Alabama, for the entire construction and completion of a school building to be erected in said city, until 12 o'clock noon of Tuesday, the eighteenth day of October, 1887, the building to be of brick, with stone trimmings, three stories high, containing fifteen school-rooms, and to be 108x76 feet.

Plans and specifications may be seen at the office of the Superintendent of Public Schools, Birmingham, Alabama, or at the office of the architect, S. J. Hall, 30 E. First Ave., Columbus, Ohio.

Bond to the amount of the contracting sum will be required. The Building Committee reserves the right to reject any and all bids.

A. O. LANE,
G. L. THOMAS,
W. J. RUSHTON,
Building Committee.

MASONRY of basement and area-walls of Post-Office, etc., at Springfield, O. Until September 10. Address Will. A. Freret, Supervising Architect of the Treasury, Washington, D. C.

IRON WORK, etc., for the Court-house at Dallas, Tex. Until September 14. Address Will. A. Freret, Supervising Architect of the Treasury, Washington, D. C.

JOINER-WORK, wood-flooring, marble mantles, roof-tiling, terra-cotta arching, plastering for Court-house at Leavenworth, Kan. Until September 16. Address Will. A. Freret, Supervising Architect of the Treasury, Washington, D. C.

HEATING AND VENTILATION of the E. Spencer Miller School, 432 1/2 Ogden Street, Philadelphia. Until September 2. Address H. W. Halliwell, Secretary of the Board of Public Education.

LAMP-POSTS AND GASOLINE FLUID needed by the city of Allegheny, Pa. Until September 2. Address James Brown, Comptroller.

COURT-HOUSE at Vandale, Cross County, Ark. Until September 5. Architect B. J. Bartlett, Little Rock. Address Thomas B. Smith, Commissioner of Public Buildings, Vandale.

BUILDING the court-house at Fort Scott, Kan., complete. Until September 17. Address Will. A. Freret, Supervising Architect of the Treasury, Washington, D. C.

REPAIRING heaters, painting, galvanizing, etc.; also, paving and furnishing iron gates for the Schuylkill Arsenal, Philadelphia. Until September 9. Address M. I. Ludington, Deputy Q. M. General, U. S. A., 1428 Arch Street, Philadelphia.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE SANITARY ENGINEER AND CONSTRUCTION RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

For works for which proposals are requested, see also the "Proposal Column," pages 341-343-344.

WATER, SEWERAGE, ETC.

EAST JORDAN, MICH.—Our correspondent writes in regard to water-works: "In reply to your inquiries, I will say that the matter is still in the hands of a committee. I don't think that anything will be done this year."

MASON CITY, ILL.—Our correspondent writes: "Our city voted on the question of issuing bonds for a system of water-works August 22. Cannot say what the result was yet. If decided in favor of bonds, I will inform you in regard to same."

MEXIA, TEX.—Our correspondent writes: "Our city is now building a water-works system; contract, \$22,000. Will be completed in sixty or ninety days."

LODO, ILL.—A committee has been appointed to sink a well for a water-supply.

MARINETTE, WIS.—The American Water-Works and Guarantee Company, which last month obtained a franchise to construct water-works here, will begin work at once.

STAFFORD, KAN.—Our correspondent writes: "The arrangement for a stand-pipe system of water-works has been completed, and work will begin in ten days."

We will have four miles of main pipe and fifty-five hydrants. Works to be built by W. A. McCoy, of Fort Scott, Kan., and to be completed by January 1, 1888."

DULUTH, MINN.—Nine dams will be built to increase the water-power on the St. Louis River. New York capitalists are interested.

GARDEN CITY, KAN.—Work on the water-works is progressing rapidly. The stand-pipe is nearly completed. Address the City Engineer for particulars.

MEDICINE LODGE, KAN.—A city election went by a large majority in favor of raising \$15,000 to introduce water.

PLATTSBROUGH, NEB.—The profiles and grades for a system of sewerage has been completed.

GREENLEAF, KAN.—We have received word from our correspondent that "The National Water-Supply Company, of Cincinnati, by John A. Wagner's steam-excavating process of sinking wells, has put in a gang of 8 wells, and has pumped them at the rate of 700,000 gallons every 24 hours for six days and is to pump them for six more to conclude the test. The rest of the works will be let by contract. Bids will be opened September 6, work to be completed December 1. The supply is a fine soft water."

LOS ANGELES, CAL.—General Bouton and N. L. Wicks propose to use the underground water below the bed of Los Angeles River for a water-supply, and have applied to City Council for permission to proceed with the works.

LOS ANGELES, CAL.—The Simi Land and Water Company filed articles of incorporation August 11. Its object is to develop the tract known as the Simi Rancho. The directors are Dan McFarland, L. T. Garnsey, L. W. Luitweiler, D. T. Perkins, Charles Forrester, and T. W. T. Richards. Almost the whole of the capital stock, \$650,000, is subscribed.

RIVERSIDE, CAL.—Among the prospective improvements are the Rubidoux Hotel, to cost \$250,000, a piped water-system, a \$100,000 high-school building, a \$50,000 opera-house, a \$50,000 casino, \$25,000 for piped water to Arlington, and electric railways. These projects, amounting to over half a million dollars, are assured, and in addition thereto a system of electric-lights, gas-works, and a hotel, to cost an amount equal to or greater than the Rubidoux, will swell the total to nearly \$1,000,000.

LARAMIE CITY, WYO., will have water from artesian wells. Address the Wyoming Central Land and Improvement Company.

ABERDEEN, DAK.—A city election will be held September 6 to vote on bonding for \$60,000 to construct sewers.

WESTERLY, R. I.—The contract for the laying of the West Side extension to the Shunoc water system was awarded August 16 to Mr. Frank A. Snow, of Providence. The pipe has just been completed at McNeal's Foundry in Burlington, N. J., and will be shipped this week, and as soon as it arrives the work will begin and will probably occupy about six weeks. Fifteen hydrants will be set.

CAMDEN, N. J.—The Water Committee of Camden City Council has authorized the clerk to advertise for bids for filter for the city water-works, with a capacity for 6,000,000 gallons, and the estimated cost for each additional million gallons.

RACINE, WIS.—The water-works were tested August 13. The system is direct pressure and stand-pipe. There are almost thirty-four miles of pipe. Two Blake pumping-engines. The works were built by Turner, Clark & Rawson, of Boston, and are owned by the Racine Water Company.

CHATTANOOGA, TENN.—August 30 an election will be held on the question of raising funds for a sewerage system.

SAN DIEGO, CAL.—Incorporated is the San Luis Rey Flume Company to construct dams, reservoirs, and canals for irrigation and water-supply. A large area has already been bought. Judge George Peterborough, E. H. Barnes, Frank H. Cunningham, C. S. Morrill are incorporators.

MILWAUKEE, WIS.—Engineer Benzenberg asks the Council for \$3,000 to put in a temporary intake for the water-works at North Point to preclude the possibility of a shortage of water at any future time.

PIERCE CITY, NEB.—A franchise has been voted to J. Guinney to erect water-works. He will commence right away. The franchise runs twenty years.

CARSON, IOWA.—Our correspondent writes: "At a special election held on the 7th of July it was voted to issue bonds for the purpose of water-works; \$200,000 was the limit of the amount of bonds that the town could issue. As yet the city has failed to receive estimates that are within the limits of the amount to be expended."

JOLIET, ILL.—Our correspondent writes: "Expect to let contract for water-works about October 1 for 20 miles from 20-inch mains down to 8-inch; 100 4-way hydrants, pumps with 8 million capacity; water from artesian wells. Works to be completed October, 1888, and the city to own works."

PAWNEE CITY, NEB.—Our correspondent informs us: "An election has been ordered for September 12, 1887, for voting for \$28,500 bonds for water-works in this city. Plans and specifications by A. A. Richardson, of Lincoln, Neb."

MINONK, ILL.—Our correspondent writes in regard to water-works: "The Council has by ordinance bonded the city in the sum of \$10,000, to bear five per cent., bonds advertised to be sold August 25, 1887. Also specifications are now in hands of contractors, and we hope to let same very soon and, have the works pushed rapidly to completion."

MT. CLEMENS, MICH.—Our correspondent writes in regard to water-works: "We have organized under State statute as 'The Mt. Clemens Water-Supply Co.' The Council of the city has as yet taken no decided action as to the expediency of the city putting in the

works itself. Until they decide that it is inexpedient for city to construct the works, and that it is expedient to have works, our company can do nothing. Address S. P. Spier, of Eldredge & Spier."

VINTON, IA.—A well for water or gas will be sunk.

MARINETTE, WIS.—The American Water-Works and Guarantee Company will build a system of water-works here.

TOPEKA, KAN.—An ordinance has been passed by city council creating Sewer District No. 13, and providing for the building of a sewerage system in the district.

MONTCLAIR, N. J.—The supply well for the Montclair water-works, which is to be 55 feet deep, has now reached a depth of 27 feet. The contractors have begun to work a double force of men, so as to drive the well day and night until its completion. The works are being constructed by McNamee & Co. of Brooklyn, well-known as the water-works contractors, and the pumping engines, to be put in by Henry R. Worthington & Co. will supply a direct pressure upon the mains, until the contractor shall complete the reservoir on the summit of First Mountain.

LONG PINE, NEB., has voted to put in water-works.

FAIRBURG, NEB.—Turner, Clark & Rawson, of Boston, have made a proposition to put water-works in here.

DUNLAP, IOWA.—The cost of the water-works which are to be constructed here will be \$10,000.

SYCAMORE, ILL.—The water-works will be improved by the addition of a stand-pipe, 135 feet high, and new pumping machinery. The cost is estimated at \$20,000. Address proposals to Water Commissioners until August 31.

BROCKTON, MASS.—Mayor Whipple has sent a letter to the Board of Aldermen asking them to appoint a committee to consider ways and means and plans for sewerage. No action has yet been taken.

TAUNTON, MASS.—The experimental wells at the pumping-station are satisfactory, and the matter of adding others to give a daily supply of 1,000,000 gallons will be brought by the Water Commissioners to the attention of Council.

PHOENIX, N. Y.—A special election, August 19, went in favor of establishing water-works by 138 to 12.

ALTOONA, PA.—The Board of Water Commissioners have draughts of ordinances in preparation looking to large expenditures for water-mains and for the Kintanog Point Reservoir.

DAVID CITY, NEB.—On August 20 a city election went in favor of raising \$20,000 for water-works.

MARSHFIELD, WIS.—Common Council is receiving bids for a sewerage system.

DREVERSBURG, TENN.—A supply of water will be obtained from artesian wells.

YORK, ME.—Six-inch iron pipe, hydrants, and force-pump will be bought to give a better fire protection. The Sanford Electric-Lighting Co. is also making tenders to furnish a supply of water here.

BELLEVUE, MICH.—It is proposed to extend the water-works at a cost of \$18,000.

OID, MICH.—On August 30 the town will vote on the question of introducing water-works.

PATERSON, N. J.—Sewerage contractors should watch for developments in Council over the proposed building of a costly sewer through solid rock in Hamburg Avenue.

RALPH, N. C.—J. L. Ludlow, C. E., has been employed by the city to prepare plans and superintend the construction of sewers. Work will be begun on the surveys at once.

NATCHEZ, MISS.—The Water Company will begin work at once to lay the main to obtain water from the river.

GREENBUSH, N. Y.—Henry W. Brown has the contract for building the pumping-house for the Greenbush Water-Works.

TOPEKA, KAN.—At the opening of bids for constructing sewers, August 17, the contract for the brick sewers was let to C. J. Rosen, total price not computed, and for pipe sewers to Decker & Mullen, price not computed. Decker & Mullen were the lowest bidders on both.

WHITEHALL, N. Y.—The Water Company will erect a new building to cost \$38,500.

ALTOONA, PA.—The contract for laying a 15-inch terra cotta sewer on Fifth Avenue, between First and Twelfth Streets, was awarded to Kelly & Co. The entire length of the proposed sewer is 4,775 feet, and includes the putting in of six inlets and the making of 20 house-taps. The contract price is \$1.17 1/2 per foot. The contractors have further agreed to put down 1,000 feet of 18-inch at the lower end of the sewer instead of 15-inch pipe at the same price.

AUSTIN, MINN.—Messrs. Loweth & Curtis, of St. Paul, are the engineers in charge of the new water-works. The contract has been let for \$36,000 to the National Brass and Iron Works of Dubuque, Iowa. Four miles of cast-iron mains, two 1,000,000 gallons compound condensing engines, fifty hydrants, a brick boiler-house and stack, and steel boilers will be furnished. Work will begin at once.

PRINCETON, ILL.—Our correspondent writes: "Nothing definite has been done in regard to water-works. At last meeting of Council there was some talk about water-works, and a committee of three was appointed to consult about the matter and to report at next meeting what in their judgment should be done."

PAXTON, ILL.—Our correspondent writes: "We expect to erect water-works this fall; have published plan and specifications for bids, a copy of which I enclose."

PAXTON, ILL.—Proposals for water-works will be opened by the Committee, August 20. The works include a tower, 80 feet high and 26 feet in diameter,

with a tank on top to hold 2,000 barrels; mains, hydrants, and pumping engine with a capacity of 250 gallons a minute. Address J. P. Middlecoff, S. P. Buhanell, O. D. Sackett, A. S. Hopkins, Committee.

PANA, ILL.—A committee has been appointed, with the Mayor, H. N. Schuyler, as Chairman, to ascertain the probable cost of water-works and where to get water.

MANITOWOC, WIS.—Plans are being prepared preparatory to advertising for proposals for building water-works.

CHICAGO.—A certificate has been filed with the Secretary of State announcing the increase of the capital stock of the Chicago Tubular Well Company, and giving notice of the change of name to the Chicago Tubular Well Works.

HAMBURG, PA.—Inquiries are being made as to sources of water for this place. Address George S. Mayer, Secretary of the Hamburg Water and Gas Company.

FORT SCOTT, KAN.—Sewerage projectors should address the Clerk of Council, or City Engineer, with propositions looking to constructing a system of sewerage here.

BEAUMONT, TEX.—Our correspondent writes "The city has levied a tax for water-works purposes, and \$14,000 bonds has been printed, signed, and sealed, and are now waiting to dispose of bonds in denomination of \$100, each with 6 per cent. interest, payable semi-annually. When bonds are disposed of the work will commence. I enclose specifications: One Blake's improved duplex pump, with two 14-inch steam cylinders, two 10-inch water-cylinders, and 12-inch stroke. There will be about 75 feet of suction-pipe, with foot-valve 12 to 14 feet under low-tide water. The water-pipe to be of 300 pounds test to the square inch; and hydrants to be used are Mathews' patent fire-hydrants. There will be about 2,060 feet of 8-inch pipe with 7 hydrants; 1,100 feet 6-inch pipe with 3 hydrants; 1,365 feet 4-inch pipe with 7 hydrants. All pipe and fittings to be tested, before covering up, with reasonable amount of pressure over working pressure. One iron stand-pipe properly connected with 8-inch pipe, and cut-off valve in connection. Bidders will make their own specifications of stand-pipe."

HOLMESBURG, PA.—The contract for the stand-pipe of the new water-works has been given to S. A. Farmer, of the Harrisburg Stove and Boiler Works, at \$5,200. The Warren Foundry and Machine Company has the contract for pipe at \$17,000.

HOOSICK FALLS, N. Y.—A village election, August 22, voted to bond the town in \$35,000 for a sewerage system. Address the Village Trustees.

CAMDEN, N. J.—Work on the improvement of the water-service has just begun. The cost is estimated at \$100,000.

WEAVER, WIS., has just obtained a water-supply from wells for fire purposes.

FLUSHING, L. I., wants proposals for laying water-mains, until September 6.

CARTHAGE, N. Y.—Our correspondent writes: "The question of water-works is being discussed at present by our taxpayers, and it is likely that a proposition to supply this village with pure and wholesome water, taken from Pleasant Lake, Champion, about four miles distant, will be submitted by the Trustees to a vote of the taxpayers soon. The proposition comes from the Canastota Water Co. Enclosed you will find an article on the subject giving a more detailed statement."

The enclosed statement is here given: "The Board of Trustees of this village have not yet entered into a contract with the Canastota Water Co. for the putting in of water-works. From present indications, however, it is probable that a contract to supply Carthage with pure and wholesome water will be made with the above company in a few days. The proposition presented to the board provides that if, after analysis, Black River water is found as wholesome as that in Pleasant Lake it will be used. If not, then the water from the lake will be used. They further agree to complete the water-main on State Street to the old cemetery before October 20, with seven non-freezing hydrants. The cost to the village will be \$400 per year for these hydrants. The Public School, village offices, and firemen's hall are to be furnished with water free of expense, also two public drinking-fountains. The company binds itself to furnish private families with water as cheaply as it is furnished in any village the size of Carthage in the State. All the expense of construction is to be paid by the company, but the village reserves the right to purchase the works at the end of any five years at an appraised value made by persons agreed upon by both parties. In time of fire the village controls the hydrants."

TORONTO, ONT.—The Water Committee has recommended to City Council the laying of a conduit across the Bay, at a cost of \$240,000.

IDAHO SPRINGS, COL.—Our correspondent writes: "We have a very fine system of water-works. We are building a new reservoir for the purpose of having a larger storage capacity; also, so that we can draw off our old reservoir and make some repairs on it."

READING, PA.—Our correspondent writes in regard to a filtering plant for the water-works: "Our Water Department has taken no action towards filtration, except to visit the Hyatt plant at Somerville, N. J. Several filtering companies have submitted propositions, but the matter has taken no definite shape as yet, and it is likely nothing will be done this year."

SPRINGFIELD, ILL.—Our correspondent writes: "There is not anything being done here now in regard to water-works. They have dug a big well near the River 'n-gamon to have filtered water, but it did not prove a success, and so all work is stopped at present, and I cannot say when they will resume work."

EAST HAMPTON, MASS.—Our correspondent writes in reference to reports from this place that nothing is being done about having water-works at present.

SAULT STE. MARIE, MICH.—A special town election has been voted in favor of raising \$10,000 for water-works.

BEACHTON, MASS.—An earnest discussion is going on here over sewerage. Address C. S. March, President of the Bechtown Improvement Society, for particulars.

WATER-PIPE.—About 170 tons of cast-iron water-pipe and special castings (4, 6, 8, 10 and 12 inch pipe), for the Rochester, N. Y., Water-Works. Until August 29. Thomas J. Neville, Clerk of the Executive Board, Rochester, N. Y.

TRENTON, N. J.—Hydrant manufacturers should note that the Chief Engineer of the Fire Department is making an inspection to decide how many additional fire-hydrants shall be erected.

HENDERSON, KY.—The Water-Works Commissioners have been authorized by the City Council to put in another pit and auxiliary pump. The pump will be a duplex, with a capacity of one million gallons in 24 hours. The cost of these additions will be about \$8,000.

LOUISVILLE, KY.—The Louisville Water Company are about to make extensive improvements.

BRIDGEPORT, CONN.—On September 3 Common Council will have hearings on the construction of several new sewers. Address the City Clerk.

TUSTIN, CAL.—Willard Bros. are prepared to supply water from their wells to the city.

SALT LAKE CITY.—City Council has awarded a contract to W. G. Childs for the construction of a new reservoir for the water-supply.

The Shields engine which is to be removed from the Cincinnati Water-Works was built in 1846. It is estimated that it has pumped 55,000,000,000 gallons of water.

GAS. STEAM. BUILDINGS. ETC.

ERIE, PA.—The project to test the natural-gas resources of the shore of Lake Erie has come to a head under the Presque Isle Natural-Gas Company. Twelve thousand dollars has been subscribed by manufacturers and business men, and the contract let to the Buffalo Oil Company, of Lima, O. The specifications require the contractors to drill the well 4,000 feet, at a contract price of between \$11,000 and \$12,000. The work will be commenced in thirty days and must be completed within four months.

HARRISBURG, PA.—The contract for heating the public buildings with steam has been given to the Harrisburg Steam Heat and Power Company at \$4,800 for the year ending June 1, 1888. For altering heating apparatus in various buildings the same company takes the contract at \$3,960. For constructing heating apparatus in the Executive Mansion the company has the contract at \$1,960.

LUDINGTON, MICH.—The Brush Electric-Light Company have contracted to put in at Ludington 25 arc-lights at \$80 each per annum.

JACKSON, MICH.—City Council has awarded the contract for street-lighting to the Thomson-Houston Electric-Light Company at \$16,000 for 180 lights burning every night.

CHARLESTON, MD.—A stock company has been formed to sink gas-wells.

MILWAUKEE, WIS.—Incorporated is the Wisconsin Electric Mfg. Co. with a capital stock of \$150,000. Alfred Miller, W. G. Roberts, and A. A. Hoskin are the incorporators, and the company is for owning and operating telephone exchanges in Milwaukee and other cities in Wisconsin.

PHILADELPHIA.—Chief Engineer Park, of the Bureau of Gas, is preparing plans for new gas-works.

BATAVIA, N. Y.—The contract for sinking the Batavia Natural-Gas Company's well has been given to Fitch Adams, of Bradford, Pa.

COOPERSTOWN, N. Y.—Incorporated is the Cooperstown Light and Power Company, with a capital stock of \$20,000. Business is carried on in Otsego. Trustees, Dudley Farlin, J. W. Hutt, C. D. Hammond, H. L. Browning, George W. Kirchway.

FORT SMITH, ARK.—The Fort Smith Natural-Gas and Power Company has been organized, and has elected the following officers: Harry E. Kelley, President; J. Henry Carnall, Vice-President; Talbot Skillman, Secretary; George T. Sparks, Treasurer. The directors elected are: J. L. Tilley, L. W. Rains, William Breen, Sam Felner, and Henry Reutzel.

JEFFERSONVILLE, IND.—Incorporated is the Ohio Falls Natural-Gas Company. Luther F. Warner, A. J. Burlingame, Simon Goldbach, and others.

CHARLESTOWN, IND.—A company has been organized here to bore for natural-gas. Dr. S. C. Taggart, M. B. Cole, F. M. Runyan, and others are directors.

CHATTANOOGA, TENN.—Organized is the Hauss Electric-Light and Power Company. D. J. Hauss, President; H. M. Wilke, Secretary.

BARABOO, WIS.—The city has granted a franchise to light the streets to a gas company.

LYNN, MASS.—The Woodward Underground Telephone and Telegraph Company has applied to the Aldermen for permission to build conduits and lay wires for the police and fire departments. A. T. Woodward is general manager.

NEW YORK CITY.—The Gas Commission opened bids August 23 for lighting the city with electricity. The American Electric Manufacturing Company put in a bid for 307 lamps at the rate of 32 cents each per night in the upper part of the city. The Harlem Lighting Company 300 lamps at 24, 40, 50 and 60 cents each, according to situation, in the upper part of the city. The United States Illuminating Company bid for an indefinite number of lights at 24, 40 and 50 cents each, according to place. The Mount Morris Electric-Light Company bid for 50 lamps only in the lower part of the city west of Broadway at 40 cents each. The North New York Lighting Company bid for 320 lamps in the annexed district at 40 cents each. The Brush Electric Illuminating Company, which received 70 cents for each light last year, bid for 140 at 25 cents and 437 at 40 cents. This company is at present getting 25 cents for each light furnished the city. The East River Electric-Light Company bid for 250 lamps at 19 1/2 cents, 401 at 19 cents, and 153 at 40 cents. The Gas Commission will award the contracts September 1.

PITTSBURG, PA.—The Shenango Natural-Gas Company is laying a new pipe-line and sinking wells. Joseph W. Craig is President; H. E. Pickett, Manager.

FORT WAYNE, IND.—Address J. B. White, President of the Business Men's Association, in regard to the pumping of natural gas from the gas fields 40 miles distant.

GAS COMPANY.—The Secretary of State filed the certificate of incorporation August 18, of the Mahoning Gas and Fuel Company of Youngstown, O., increase of capital stock from \$300,000 to \$500,000.

CHICOPEE, MASS.—The Chicopee Electric Light Company has assumed the contract made with the Thomson-Houston Company for lighting the streets, and will go on with the work.

LITCHFIELD, CONN.—The County Commissioners will advertise for proposals to erect jails at Winsted and New Milford. The plans and specifications for jails and purchase of sites are estimated to call for \$71,989.49.

CANASTOTA, N. Y.—At the election August 18 a resolution was carried by a vote of 125 to 49 in favor of electric lights for the streets. The board of trustees will advertise for bids.

CHARLESTON, S. C.—The Charleston Light and Power Co. will increase their plant at once.

STREET WORK AND PAVING.

BRAINTREE, MASS.—The Selectmen ask bids, until August 29, for building a road from Pearl to Liberty Streets in South Braintree. Address A. O. Clark, Chairman of the Board of Selectmen.

NORTH KINGSTON, R. I.—A report has been prepared on the maintenance of highways.

FULLERTON, CAL.—A large amount of street improvement will be done here. Work on Commonwealth Avenue will be pushed.

STANTON, MICH.—The City Council has ordered a special election for the purpose of voting on the question of bonding the city for improving the highways. The special election will occur on Monday, September 5.

LOS ANGELES, CAL.—An extensive park improvement will be made on the Dominguez property, under direction of William H. Hall, State Engineer. The owners are Judge Charles Silent, D. McFarland, and N. R. Vail.

SAN FRANCISCO, CAL.—A large amount of street paving and sidewalk works is proposed.

TRENTON, N. J.—Bids for paving Clinton Avenue were opened by the City Council August 19 as follows: For resurfacing the present Telford pavement by B. M. & J. F. Shandley: for excavation of earth per cubic yard, 60 cents; for resurfacing with trap rock stone, which will be rolled with a 20-ton steam-roller, per yard, 50 cents.

Martin Van Harlingen, of Philadelphia, presented several bids as follows: for excavation earth per cubic yard, 40 cents; and for Cape Ann granite per square yard, \$2.50; for Philadelphia asphalt block per square yard, \$2.40, with same price for excavation as before; for Goat Hill stone, per square yard, \$2.47, with same price for excavation as in first bid.

D. Lodor, for repairing the avenue with Telford paving, bid 85 cents per square yard, with 35 cents per cubic yard for excavation. For repairing with top dressing, without disturbing the present bed, he bid 65 cents per square yard. Mr. Lodor bid \$2.25 per yard for reaving the street with compressed asphaltum block from Norristown, the excavation to cost the same as before. He also put in bids on granite block and Goat Hill stone, the excavations in each case to be at the rate of 35 cents per cubic yard; granite block \$2.65 per yard, and Goat Hill stone \$2.05 per yard.

The Vulcanite Paving Company, of Philadelphia, bid, saying: "First, we will grade off the surface of the street adjoining the gutter stone for a distance of two feet out, and to a depth of three inches below the top of the gutter-stone, and thoroughly scrape and clean the street. We will then level up all inequalities by placing thereon a hydraulic concrete, composed of Portland cement and sharp gravel. On this, when properly set, we will lay 7 1/2 inches compressed Trinidad asphaltum, for the sum of \$2.15 per square yard. Secondly, we will grade the street to a depth of four inches from the top of the gutter-stone, and for a width of two feet out, and then lay a binder of 2 1/2 inches thick, and finish up with a top coat or wearing surface 1 1/2 inches thick of Hilbert's vulcanite asphaltum, laid as per specifications attached, for \$2.25 per square yard complete. Third, we will grade as in our No. 2 bid and lay a binder of 1 1/2 inches in thickness and on that lay 2 1/2 inches of vulcanite, composed of 3/4 Trinidad asphaltum and 1/4 composition distillate of coal tar, properly mixed with sand and brought to perfect grade, for the sum of \$2.10 per square yard, complete. K Street in Washington City was laid with this pavement in 1875, and is in perfect condition to-day, without one dollar in repairs ever being put on it. Either of the above pavements we will roll with a steam-roller. We guarantee to keep the street in repair for three years."

ROCHESTER, N. Y.—The Rochester and Charlotte Turnpike Company, the Rochester City and Brighton Railway Company, and the Electric Railway Company have all made propositions to the city to build and operate a line of railway down the Boulevard to the Lake. Address Patrick Cox, of the first-named company.

DES MOINES, IOWA.—City Council has passed the ordinance providing for the construction of a viaduct on Summit Street. The cost will be about \$100,000.

ELIZABETH, N. J.—Bids for paving various streets with trap-block, will be opened September 8, by M. M. Watson, Street Commissioner.

SAN DIEGO, CAL.—The principal streets will be paved with bituminous rock.

BROOKLYN.—Chief Engineer Van Buren has prepared plans for raising the grades of streets in the Ninth Ward and the plans are now before Common Council.

ROCHESTER, N. Y.—Council has approved of the following work: Kelly Street macadam improvement; Monroe Avenue asphalt improvement.

BRIDGES.

CHATTANOOGA, TENN.—The stock is nearly subscribed for the building of a bridge over the Tennessee River. The structure will be an iron truss, about 2,000 feet long, including approaches. It is announced that the contract will be given to a Southern company.

Messrs. Merriam & Jarnigan can give further information.

ELIZABETH, PA.—It is proposed to bridge the Monongahela River at this place. The cost will be about \$100,000.

CAIRO, ILL.—The first of the caissons for the bridge over the Ohio River was launched August 20. The Union Bridge Company are the contractors. A. Noble is resident engineer.

SUMMIT, N. J.—It is proposed to build a new iron bridge over Linden Avenue.

FORT JERVIS, N. Y.—The contract for a bridge over Neversink River has been given by the Town Board to the Groton Bridge Company.

LEAVENWORTH, KAN.—The bids recently opened for a bridge on Fifth Street were found to be too high. Proposals will be re-advertised for.

JACKSONVILLE, FLA.—A bridge will be built over Hogan's Creek at Laura Street. Address W. A. Bisbee for further information.

ALFORD, MASS.—The special town meeting has voted to instruct the Selectmen to build an iron bridge across the Green River, known as Williams Bridge. The Selectmen have contracted for the same with the Berlin, Conn., Bridge Company, the town to build the abutment.

NEW YORK CITY.—Proposals for improving the unfinished part of Riverside Avenue, between Eighty-fifth and Eighty-eighth Streets, will be received by the Department of Parks until September 7.

ROCKVILLE, CONN.—Town meeting has decided that an iron bridge shall be built across the river at Talcottville.

NEW ULM, MINN.—On August 20 a mass meeting resolved that Council should be requested to have an iron bridge built over Minnesota River. The Aldermen favor it.

CHATTANOOGA, TENN.—The Anderson Bridge Company is just organized to build a bridge over the Tennessee Market Street. Rough estimates place the cost at \$300,000. Address C. C. Anderson.

NIAGARA FALLS.—The new suspension bridge over the Niagara River, N. Y., will be altered to give a double roadway for teams.

ROCHESTER, N. Y.—The City Engineer is making an estimate of the cost of a new bridge over the river between Alexander and Edinburg Streets.

RUSHFORD, WIS.—Address Supervisor Loope in regard to a proposed iron bridge to be built this season.

OWASSO, MICH.—A new iron bridge will be built over the Shiawassee River at Shiawassee Street.

ST. LOUIS, MO.—The St. Louis Merchants' Bridge and Terminal Railroad Co. filed articles of incorporation in the Secretary of State's office August 18. The bridge is to be erected in the corporate limits of St. Louis; capital, \$1,000,000. The directors are: Seth W. Cobb, C. C. Rainwater, John D. Perry, John M. Gilkerson, John Whittaker, John R. Holmes, and John H. Overall, all leading business men of this city.

MILLEDGEVILLE, GEO.—A bridge will be built over the river here.

RAILROAD BRIDGES.—The Berlin, Conn., Iron Bridge Company has the contract for about 40 bridges on the Mendon and Waterbury Railroad.

BRIDGES.—Bids are now being received for the construction of bridges over the north and south branches of the Shenandoah River. For further particulars address M. L. Garrison, Front Royal, Va.

VISALIA, CAL.—\$12,000 will be applied to town improvement, beginning work at once.

MIDDLETOWN, R. I.—Bids for improving Second and First Beach Avenues will be received by Albert L. Chase, Town Clerk, until September 1.

MUSCATINE, IOWA.—Messrs. Edwards & Walsh have been awarded the contract for building a stone-arch bridge over Papoose Creek; cost, \$5,975.

HARTFORD, CONN.—The contract for building an iron bridge over the Connecticut for the New England Railroad Co. has been awarded to the Boston Bridge Works; cost, \$75,000.

NEW BRITAIN, CONN.—A new bridge is to be built at the Black Rock Crossing of the New England Railroad.

HINDOSTAN, IND.—The commissioners of Martin County propose building a bridge over White River at this place to cost about \$40,000.

BIDS OPENED.

MARSHALL, ILL.—The contract for building the courthouse was awarded August 22 to J. M. Bell, of Paris, and for steam-heating to Watson & Sons, of Terre Haute.

NEW YORK CITY.—Bids for work on the Eighth Regiment Armory were opened by the Armory Board, August 25, as follows:

Mason work: Dawson & Archer, \$175,000; John Cox, \$176,934; James H. Brady, \$177,555; Isaac H. Hopper, \$178,750; Moran & Armstrong, \$144,443; and Edward D. Connolly & Sons, \$160,370.

Carpenter work: McGuire & Sloan, \$92,691; Thomas Overington, \$54,900; Daniel Smyth, \$74,500; James M. Brady, \$67,800; and Mahony Brothers, \$75,780.

Plumbing work: Charles Nally, \$9,250; Scott & Newman, \$10,800; P. J. Andrews, \$10,933; George Cody, \$7,840; John Spence, \$9,500; and John Renahan, \$9,000. The only bid made for the iron work was by the Wallis Iron Works for \$107,047.

For steam-heating and ventilating apparatus the lowest bidder was Baker, Smith & Co., for \$11,745.

It was decided to re-advertise for iron work. The Board expects to supervise the bids so as to confine the total cost of the armory to \$300,000. The estimated cost of the armory is \$325,975.

MILWAUKEE, WIS.—New school building in the Ninth Ward. For the building: Charles Kraatz, \$22,448; A. H. Vogel, \$22,648; F. Niezorski, \$22,850; H. Schlenstedt, \$22,970; G. F. Stuewe, \$23,500; Henry Tesch, \$23,637; William Klocksin, \$24,500; J. H. Lemcheek, \$25,250; Wenzel Strachote, \$25,385.

For the steam-heating apparatus: H. Mooers & Co., \$3,740; M. Coogan, \$3,340; Charles A. Barker, \$2,929.

For the plumbing: William E. Goodman, \$910; P. H. Murphy, \$890.

The contracts were let to the lowest bidders. The Union School Furniture Co. will furnish the desks and seats: "C" and "D" desks, \$3.15 each; "E" desks, \$3.05 each; fronts and backs of all sizes, \$2.75 each.

WATERVILLE, N. Y.—The following bids for water-works construction were received by I. D. Brainerd, President of Water-Works Trusts, August 20:

Sullivan & Stafford, Little Falls, N. Y., for the works complete, \$50,600.57.

Sherman & McDonough, Utica and West Troy, for the works complete, \$51,450.

Riden & Dougherty, Vonkers, N. Y., for the works complete, \$55,566.81.

Chambers & Casey, Rochester, N. Y., for works, except pipe and specials, \$28,777.30.

G. W. White, Pulaski, N. Y., for the works complete, \$51,047.90.

Sullivan & Stafford, for work only, \$24,673.12.

Chambers & Casey, for work only, \$26,442.10.

G. W. White, for work only, \$22,754.30.

Warren Foundry and Machine Co., Reading, Pa., pipe, \$22,304.50; specials, \$428.25.

C. Millar & Son, Utica, N. Y., pipe, \$22,745.96; specials, \$415.76; hydrants, \$1,484.75; valves, \$648.55; valve-boxes, \$100.

R. D. Wood & Co., Philadelphia, pipe, \$24,049.35; specials, \$438.11; hydrants, \$1,484.75; valve-boxes, \$98.25.

Mellert Foundry and Machine Co., Reading, pipe, \$25,393.80; specials, \$381.37; hydrants, \$1,336; valves, \$668.

Builders' Iron-Works, specials, \$400.25; valve-boxes, \$99.

Eddy Valve Company, hydrants, \$1,210; valves, \$611.40; valve-boxes, \$99.

Tamaqua Manufacturing Co., Tamaqua, Pa., hydrants, \$1,207.

Chapman Valve Mfg. Co., hydrants, \$1,136; valves, \$656.41.

Ludlow Mfg. Co., hydrants, \$1,411; valves, \$668.10; valve-boxes, \$110.28.

Coffin Valve Mfg. Co., valves, \$556.

Contract awarded to G. W. White, Pulaski, N. Y., for work only, village to furnish pipes, hydrants, and valves. Contract price for work \$22,754.30.

ST. LOUIS.—The following bids for 30 tons of 3 and 4-inch water-pipe and 50 tons of special castings were received by the Board of Public Improvements, August 15: Shickle, Harrison & Howard Iron Co., St. Louis, water-pipe, \$39 per ton, total, \$1,170; special castings, \$55 per ton, \$2,750. The contract was awarded at those figures.

BRAINTREE, MASS.—The following bids for laying about twelve miles of cast-iron water-pipe in the town of Braintree, were received by the Water Commissioners, August 15:

John Cavanagh, Braintree, 16-inch pipe, 50c. per foot; 12-inch, 40c.; 10-inch, 35c.; 8-inch, 30c.; 6-inch, 25c.; 4-inch, 20c.; total, \$10,508.15.

John O'Connor, South Boston, 16-inch, \$1; 12-inch, 80c.; 10-inch, 70c.; 8-inch, 60c.; 6-inch, 50c.; 4-inch, 40c.; total, \$9,036.30.

A. H. Howland, Boston, for all, \$16,346.18.

W. C. McClellan, Boston, for all, \$22,000.

The contract is not yet awarded.

LYNN, MASS.—The following bids for constructing Section 3 of Haskell Intersecting Sewer were received by John C. Haskell, City Engineer, August 22:

BIDDER AND RESIDENCE.		
Edward F. Brigham, Cambridge,	95 00	Cu. yds. earth exc., 10,824, A.
Edward C. McCallan, Boston, Mass., ..	1 21 30	Cu. yds. rock exc., 200, B.
James Heath, Lynn, Mass.,	70 5 00	Cu. yds. earth exc., refilling above grade, 200, C.
	57 0 00	Cu. yds. concrete, 67, D.
	11 25 00	Cu. yds. brick masonry and cement mortar, 1,650, E.
	11 25 00	Cu. yds. rubble stone masonry, 30, F.
	50 0 00	Linear feet 10 in. drain-pipe in place, 3,480, G.
	23 0 00	M. ft. B. M. per lumber in place and secured, 10, N.
	65 0 00	Catch-basins, 21, I.
	65 0 00	12" conn. pipe from basins to sewer, 350, J.
	50 0 00	Superficial feet footing stone, 190, L.
	50 0 00	Purch stone masonry in sidewalks, 35, M.
	75 0 00	Superficial feet covering stone, 565, N.
	75 0 00	Linear ft. of 18" drain-pipe in place, 45, O.
	80 0 00	Linear ft. of 12" drain-pipe in place, 318, P.
	33 317 95	Total.

LYNN, MASS.—The contract for building sewer from Bay Meadow to the eastern terminus of the intercepting sewer (Sec. 3) has been awarded to James Heath.

THE SANITARY ENGINEER AND CONSTRUCTION RECORD.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1887, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 16. }
NUMBER 14. } PUBLISHED EVERY SATURDAY.

NEW YORK, SEPTEMBER 3, 1887.

LONDON, SEPTEMBER 17, 1887.

SINGLE COPIES, TEN CENTS.
Subscription, \$4.00 per year in advance, post paid. } IN AMERICA
SINGLE COPIES, SIXPENCE.
Subscription, 20s. per annum in advance, post paid. } IN GREAT BRITAIN.

THE SANITARY ENGINEER AND CONSTRUCTION RECORD, conducted by HENRY C. MEYER, is published every Saturday at 82 & 84 Fulton Street, New York. Its opinions upon all technical subjects are either prepared or revised by specialists.

TERMS, \$4 PER YEAR, IN ADVANCE.

Postage Paid.

OFFICE IN GREAT BRITAIN,
92 & 94 FLEET ST., LONDON.

TERMS, 20s. PER YEAR, IN ADVANCE. Postage Paid.
SINGLE COPIES, SIXPENCE.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE SANITARY ENGINEER AND CONSTRUCTION RECORD (New York), and crossed — & Co.

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzig, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, \$5; China, Japan, Sandwich Islands, Mexico and Cuba, \$5; South America, \$5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us promptly of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money order payable to THE SANITARY ENGINEER AND CONSTRUCTION RECORD.

When a change of address is desired, both the old and new addresses should be given.

THE RIGHTS OF THE PEOPLE TO WATER FOR THE USE OF TOWNS AND CITIES.

THIS question is one that is destined to become increasingly prominent as the population increases, the country becomes more developed, and the available supply of water in times of scarcity becomes less and less. This subject is presented under the head of a "Resource for Cheap Water for the People" in the last publication of the New England Water-Works Association. It seems that in at least two States (Massachusetts and Maine) all natural bodies of water of over ten acres in area are legally styled "Great Ponds," and have always been public property—no private title approaching nearer than low-water mark. The State of Massachusetts has adopted the principle of giving this water free to municipalities requiring it. The argument by T. M. Stetson, Esq., submitted at the time of the application of Fall River for condemnation of the water of Watuppa Ponds, is given in full in this paper. It is based on two propositions:

"First—The State owns the water in these 'Great Ponds' and may well give from it to its people without toll or payment.

"Second—That any ancient licenses or privileges heretofore allowed to parties to use, control, and avail of the surplus waters after they pass into the outlet stream (the Quequechan or Fall River) shall, so far as they legally may, be revoked or prevented from standing now in the way of the proposed gift from the State to its people."

The opponents of the application held that they had a prior right from continued use under a license given in 1826, but the argument states that the Supreme Court of the United States had in three cases decided against the irrevocability of such licenses.

The State had in 1647 consecrated the Great Ponds to the public forever, and Justice Hoar upheld this in a written opinion, stating, "There is no adjudged case in which any right in them adverse to the public has ever been recognized." This same opinion quotes from several other opinions as follows:

"Riparian owners on the stream own the uses of the water that actually succeeds in getting into the stream, but that is all.

"The use which every owner in a running stream may claim is only of the water which has entered into and become a part of the stream.

"The grant by the Legislature of an exclusive right to the water-power of a navigable stream does not give title to the corpus of the water. Hence a subsequent grant to the district to erect water-works to supply its inhabitants with water is not in violation of the previous grant of the water-power.

"An upper owner has an unqualified right to drain his marsh, and a neighboring proprietor cannot complain of deprivation of water which would otherwise come to his land, etc.

"Water taken from a pond before it could reach the outlet never could be water flowing from the pond.

"In short, until water gets into a defined water-course, it has no relations with the riparian owners along such water-course. The line of demarkation of the title is at the point where the water *de facto* leaves the Great Pond and enters the water-course. Till then it belongs to the State, afterwards to the riparian owners on the stream."

Numerous other decisions are quoted to show that no license by the State can be held to be

irrevocable, or to withhold the State from exercising its sovereignty should occasion arise.

So in this case "the ancient policy was to encourage mills, but never at the expense of the people's thirst and cleanliness.

The bill that was passed last year in the case of the city of New Bedford is appended. It provided for the taking and using of the waters of Little Quitticas Pond, without liability for other damages than the State itself would be liable to pay.

The city of Worcester is now defending a suit for diversion of water, but the testimony thus far published is too meagre to give an intelligible statement of the case. It is well that all who are interested in water-works become fully acquainted with the principles underlying such cases, so clearly and admirably stated in the one before us.

COMPARATIVE SANITARY CONDITION OF THE PRINCIPAL CITIES OF EUROPE IN 1886.

IN *Revue d'Hygiene* for June, 1887, Dr. Jacques Bertillon, the Chief of the Bureau of Statistics of the city of Paris, publishes a memoir under the above heading, being a continuation of a similar report made by him last year, which was duly noticed in THE SANITARY ENGINEER AND CONSTRUCTION RECORD.

In this paper he gives the proportion of deaths per 100,000 of living population for each of certain preventable diseases. The proportion of deaths per 100,000 of population reported as caused by typhoid fever during the year 1886, was, for Paris, 46; Marseilles, 108; Bordeaux, 60; Lyons, 40; Nancy, 65; Toulouse, 118; Besancon, 205. These are high figures as compared with those for the cities of other countries,—as, for example, London, 17; Edinburgh, 15; Liverpool, 34; Manchester, 33; Berlin, 16; Dresden, 18; Leipzig, 11; Vienna, 11; Brussels, 29; Amsterdam, 16; Copenhagen, 13.

A few large cities have, however, suffered greatly from this disease—e.g., Saragossa 128; St. Petersburg, 113; Milan, 71; Philadelphia, 65; Baltimore, 46.

The great outbreaks of small-pox during the year are shown by the following figures, giving numbers of deaths per 100,000—viz.: Marseilles, 573; Rheims, 110; Budapest, 358; Saragossa, 221; Rome, 128; Milan, 64; Zurich, 106. In like manner some of the figures for scarlet fever were: Paris, 18; Lyons, 13; Marseilles, 5; London, 17; Liverpool, 47; Leeds, 57; Glasgow, 68; Berlin, 21; Hanover, 285; Leipzig, 28; Munich, 34; Budapest, 127; Vienna, 16; Amsterdam, 6; Rome, 5; St. Petersburg, 93; Brooklyn, 51.

For diphtheria in like manner some of the figures were: Paris, 73; Marseilles, 163; Lyons, 38; London, 33; Liverpool, 21; Glasgow, 29; Edinburgh, 32; Berlin, 128; Dresden, 169; Hamburg, 123; Leipzig, 110; Munich, 86; Nuremberg, 240; Budapest, 128; Amsterdam, 74; Grenada, 491; Rome, 52; St. Petersburg, 63; Brooklyn, 170; Philadelphia, 113.

All the above diseases are liable to occur in epidemic form, and an outbreak in a particular city may make it appear very unhealthy for that year, although ordinarily its sanitary condition is good. It is different with another disease of which Dr. Bertillon gives the statistics, and for which the figures do not show such great differences. This is consumption, from which in each

100,000 inhabitants there died in Paris, 470; Marseilles, 448; Lyons, 444; London, 202; Glasgow, 278; Edinburgh, 193; Belfast, 472; Berlin, 334; Dresden, 387; Leipzig, 315; Munich, 390; Nuremberg, 482; Budapest, 708; Vienna, 664; Brussels, 315; Rome, 212; Brooklyn, 313; New Orleans, 382; Philadelphia, 296.

It will be found interesting to compare these figures with those for the preceding year, and on doing so it will be found that the changes have not been great, but are mostly for the better; that the French cities suffer most from typhoid, the English from scarlet fever, the German from diphtheria, and the Austrian from consumption.

NEW YORK AQUEDUCT COMMISSIONERS' REPORT.

THE New York Aqueduct Commissioners are to be commended for the wise expenditure that has given to the public and the profession so valuable a publication as their reports for the

undertaking, and engineers are often to blame if the expenditure be not authorized, though we believe in the case of the Brooklyn Bridge the failure to make it was due to a false notion of economy on the part of the trustees. In the case of the aqueduct report the receipts from sale of copies are expected to nearly cover the cost of publication.

AMERICAN PUPILS' PRIZE AT ECOLE DES BEAUX-ARTS.

ELSEWHERE in this issue will be found a quotation from *La Semaine des Constructeurs* giving an account of the foundation of an annual prize for French students of the Department of Architecture at the Ecole des Beaux-Arts. The fund was made up of contributions from certain American architects, former pupils of the Paris school, and a few friends interested in the profession of architecture. The seven thousand dollars thus donated is a generous response from

templated in this prize foundation. Indeed, it would be much easier to secure an endowment for an art school to be located in the bottom lands of Arkansas.

IN connection with our note on "How to Dress in Hot Weather," given in THE SANITARY ENGINEER AND CONSTRUCTION RECORD for August 20, attention is called to the communication from General M. C. Meigs, printed in another column, which gives some positive data as to the temperatures to which those who dress in black clothes in the summer may be exposed.

OUR SPECIAL ILLUSTRATION.

RESIDENCE OF WILLIAM EDGAR, NEWPORT, R. I.—M'KIM, MEAD & WHITE, ARCHITECTS.

OUR special illustration is of the residence of William Edgar, Esq., Newport, R. I. McKim, Mead & White are the architects.

period 1883-1887, a synopsis of which we give elsewhere in this issue; an acknowledgment is likewise due Mr. B. S. Church, the Chief Engineer, and the Secretary, Mr. J. C. Sheehan, for the great labor involved in the preparation of the mass of statistics given. The illustrations help to lighten up the report and to give a clearer idea of the arrangement, while the constructive details are of great value and will be fully appreciated by engineers.

It is a pity that those responsible for the affairs of the East River Bridge should have been willing to let the great mass of valuable experience obtained in its construction be in a measure lost. The annual reports issued cannot take the place of a fully illustrated report, and each day it will become more and more difficult to reproduce the details as left by the builders. Drawings become scattered, lost, or illegible, and note-books, on which so much depends, very soon disappear. The public is always willing to bear this portion of the expense of an engineering

the limited number who knew anything of the movement and contributed the money.

We have a letter suggesting that the originators of the movement to raise this fund should have "endeavored to secure from the National Congress an appropriation of a sum of money as a substantial endowment, to be deposited with the *Ecole des Beaux-Arts*, not merely in the name of American architects, but also to include the thousands of sculptors and painters who have profited so largely by what they have studied under the French master."

Even it were proper to appeal to the Government for funds for such a purpose, we think the committee acted wisely in not attempting so quixotic a scheme. What they have so quietly done is a graceful act of appreciation, and is so considered by the French friends of the school. Moreover, the views entertained by Congress on questions of this sort would lead us to conclude that no architect now living would live to see an appropriation made for any such purpose as is con-

OUR VIGNETTE ILLUSTRATION.

RESIDENCE OF GEORGE P. SAWYER, BUFFALO, N. Y.
GREEN & WICKS, ARCHITECTS.

THE subject of our vignette illustration is the house of Mr. George P. Sawyer, on Ferry Street, Buffalo, N. Y. It is of wood, all the stories shingled. White oak in dining-room and hall, elsewhere pine, painted; colonial finish. The plastering in halls and dining-room is in wire gauzed pebble, dark. The cost was \$10,000. The architects were Messrs. Green & Wicks, of Buffalo, N. Y.

BRICK PAVEMENTS IN CHARLESTON.

MR. T. A. HUGENIN, Superintendent of Streets, Charleston, S. C., writes us in response to our reference to a brick pavement in Cincinnati, on page 318, issue of August 20, that bricks prepared in accordance with a method patented by him have been "laid in Charleston for three years, and subjected to the heaviest traffic" of that city "with entire satisfaction, showing less wear than the granite block immediately adjacent."

THE AMERICAN PUPILS' PRIZE AT ECOLE DES BEAUX-ARTS.

[Translated from *La Semaine des Constructeurs*.]

A NUMBER of American architects, former pupils of the Ecole Nationale des Beaux-Arts, and other generous citizens of the United States, have recently made a gift to the school of a sum of 35,000 francs, to establish a prize in favor of the French pupils of the department of architecture.

Their delegate, M. Richard Hunt, architect, correspondent of the Académie des Beaux-Arts, in the following terms informs M. Paul Dubois of this liberality, which attests the deep gratitude of the donor toward our country:

THIRD ANNUAL EXHIBITION OF THE ARCHITECTURAL LEAGUE.

THE third annual exhibition of the Architectural League will be open to the public at the Fifth Avenue Art Galleries, 366 and 368 Fifth Avenue, New York City, on Monday, December 19, 1887, and will continue for three weeks.

The exhibition will consist of work not before exhibited in New York City, and representing, as far as practicable, the work of the past year.

The exhibition is to be devoted to architecture and the allied arts, as may be represented, as follows:

Architectural designs, perspective drawings, sketches in pencil, pen and ink, water colors, charcoal, etc., elevations and photographs of executed work.

Sketches for interior decoration and furniture, designs, and cartoons for stained glass, mural decoration and paintings of foreign work.

Stained glass, wood carving, mosaic, and casts and models of executed architectural and decorative work.

A detailed circular of blanks as to jury, framing, transportation, etc., is now being prepared and can be had after October 1 on application to the Secretary, Charles I. Berg, at 152 Fifth Avenue, New York.

The building is of brick, trimmed with New Jersey freestone. It is fire-proof, the floor-beams, partitions, and stairs being of iron, and the roofs of iron, asbestos, and slate. There is no wood-work on the exterior, all cornices and dormer windows being of stone. The windows and porches are ornamented with handsomely carved capitals in different designs.

The basement story is ten feet high, and is designed to contain a sitting and reception room for employees, a sewing-room, toilet and storerooms, an accident-reception ward and an examining-room. In this basement is to be placed the heating-apparatus for the building, to consist of boxes enclosing steam-coils, which receive supplies of fresh air from air-ducts leading to them from a common inlet, the supply being insured and regulated by a fan. These boxes each communicate with flues that pass upwards in the walls of the building to the various rooms on each floor, where they open by suitable registers. These flues are made of galvanized iron, and in each case their capacity has been made the subject of careful calculation, to insure the full delivery of an adequate amount of fresh air in the room supplied by it. An inspection of Fig. 2 will show the course of the primary air-ducts, as they form a part of the foundation plans of the buildings. There will be seen also an extension of these air-ducts to the pavilions. In the pavilions, however, they are merely accessories to a different system of air-supply, arranged for those buildings, which will be described in an appropriate connection. It should be noted here that from all the rooms of the main central building adequate exhaust-flues to carry off vitiated

"SIR: The architects of the United States, feeling a sincere gratitude toward the Ecole des Beaux-Arts, desire to give to their sentiments an expression which will forever recall the generous bounty of the school, so lavish in its care for the artist students of all nationalities.

"They desire to found for the French architectural pupils of the school an annual prize which shall be entitled 'Prix de reconnaissance des architectes Américains.'

They desire to found this prize in favor of the French pupils alone, in order the better to accentuate their gratitude toward France. To this end, the former pupils of the school and others have subscribed the sum of thirty-five thousand (35,000) francs.

They desire that the interest on this sum shall constitute an annual prize.

Hoping that this communication will be received with favor, and reiterating their expressions of gratitude, they pray you, Monsieur le Directeur, to accept the assurance of their devotion and of their highest consideration.

(Signed)

RICHARD M. HUNT,
President.

The secretary has also issued a circular, accompanied by a blank form, requesting architects to furnish him with their full names and addresses, the purpose apparently being to secure a correct list of the profession.

GENERAL DESCRIPTION OF THE METHODIST GENERAL HOSPITAL.

THE plot of land constituting the hospital grounds consists of the entire city block bounded by Seventh and Eighth Avenues and Sixth and Seventh Streets, in the city of Brooklyn. The grounds are rectangular, being 695 feet 9 inches from east to west, and 200 feet from north to south. The architect was Mr. John Mumford, of Brooklyn.

THE BUILDINGS.

The buildings front upon Sixth Street, and consist of a main central building, an accessory central building, and two pavilions, one on either side of the main building. The basements only of these buildings are connected by light corridors.

The Main Central Building is 155 feet 6 inches in length and 92 feet in depth, exclusive of the tower, which projects 19 feet. The height to the top of the cornices is 61 feet 8 inches, and to the top of the tower 126 feet.

air lead, which are gathered together beneath the roof above, where they open into appropriate louvred lanterns to discharge their contents into the outer air. There will be an elevator from the basement to the third story.

The first story will be 18 feet high, and will contain the manager's room, general reception-room, officers' and nurses' dining-rooms, superintendent's and clerks' offices, toilet-rooms, and the chapel. The latter is octagonal in plan, with ceiling 22 feet high, and will seat 160 persons. The plan is so arranged that the public can attend services in it without entering the hospital proper.

The principal entrance to the building is through a vestibule 17 feet 6 inches wide. This opens into a grand corridor 30 feet wide, from which springs the main staircase. The central portion of this corridor forms a rotunda, 17 feet in diameter, which is supported by cast-iron columns, and extends upwards to the roof, where it is surmounted by a glass dome light.

The second story, 15 feet in height, is planned to contain living-rooms for the superintendent and matron, and a number of private rooms for paying patients. A room for a library and museum purposes is provided over the chapel. This room is octagonal in plan, 40 feet in diameter, with ceiling 24 feet high, surmounted by a large skylight.

The third story is 13 feet high, and is arranged for one ward of ten beds, with the necessary service rooms. Six

smaller rooms for patients are also provided for on this floor.

The fourth story is intended to be devoted to dormitories for nurses, and will afford ample accommodation for thirty persons.

On each floor, from the basement to the fourth story, isolated by a branch corridor of some length, toilet-rooms are placed in the north-western corner of the building, provided not only with abundant cross-ventilation by windows, but also with a special exhaust ventilating-chimney, into which flues lead from each water-closet bowl. The walls of the toilet-rooms are built of enameled bricks.

In this part of the building, also, is placed a second staircase which, beginning at the basement, communicates with every floor.

This building, besides providing for the various administrative offices and residences, the chapel and museum, and the home for nurses, will afford accommodations of a superior character for about 30 patients.

THE ACCESSORY CENTRAL BUILDING.

This building will be placed directly in the rear of the main central building, and be connected with it by a covered corridor. It will be 54 feet deep and 80 feet wide, and will front on Seventh Street. It will be two stories in height, with a high mansard roof, containing a full story and an attic. It will have a basement, in which will be placed the boilers, engine, coal-vaults, and fan-blowers for supplying the air-currents, brought through ducts leading from large ornamental shafts in the grounds adjacent to the general system of fresh-air ducts of the institution.

The first story will contain a kitchen, preparing-room, bakery, storerooms, and refrigerators.

The second story will contain the laundry ironing-room, employees' dining-room, and apothecary's shop.

The third story will be occupied exclusively for dormitories for employees, with necessary toilet-rooms.

In the attic there will be a disinfecting-room.

THE PAVILIONS.

These contain the main or common wards, and the necessary service rooms. There are two of them, alike in every respect, one on each side of the main central building, and distant from it 40 feet. The extreme width of the front or service portion of each pavilion is 60 feet, and the total depth of the pavilion is 150 feet. The portion containing the wards is of two stories, with a basement. The basement is 9 feet high, entirely above ground, fully lighted by windows uniform in number with those of the floors above, with concrete floors, plastered ceilings, and whitewashed walls. It will contain nothing except the apparatus for heating and ventilation.

The wards proper are rectangular, 96 feet long and 32 feet wide. Their height is 15 feet. There is one window to every two beds; the windows on the two sides are placed directly opposite each other, and in the upper part of each window-frame is a transom-sash. The long axis of the wards runs nearly north and south, and the wards have a full and uninterrupted exposure upon the east, south and west sides respectively. Each ward is calculated to contain twenty-four beds, and in that case would provide nearly 2,000 cubic feet of air-space, 128 square feet of floor-area, and a wall-space of 8 feet, including windows, to each bed. A constant and copious supply of fresh air is provided for by registers placed in the walls between each window, which communicate with flues that lead to external openings in the basement-walls eight feet above the surface of the ground. These flues also communicate with heating chambers, enclosing steam-coils, placed in the basement, and, by suitable valves, the air-current may be made to pass through these heating chambers, or directly upward into the ward above. The temperature may thus be regulated, but in no case can the volume of air be interfered with. These flues likewise communicate with the air-ducts leading from the central fans described in connection with the main central building, by means of which the power of forcing or accelerating the ventilation of the wards will be supplied whenever the natural powers of aspiration, upon which the ward system of air-supply depends, is found deficient.

For the removal of vitiated air from the wards equally complete provision is made by means of two great aspirating chimneys in each pavilion. From apertures, suitably guarded, beneath the foot of each bed in the floors of the wards, and from a series of registers placed near the ceiling of the lower ward, and along the centre of the ceiling of the upper ward, foul-air ducts lead that converge to common ducts that finally empty into great aspirating chimneys, where, by means of steam-coils, a constant force of aspiration is maintained. The arrangement of the floor foul-air flues of the lower ward is well shown in the plan of the pavilions.

In addition to these, four open fire-places are provided in each ward, one in each of its corners. Each of these becomes, when in use, an accessory aspirating flue.

The wards open at their northern end into a wide corridor, which is enlarged so as to form a convenient sitting-room for convalescents. Around this cluster the service rooms for each ward. The arrangement is shown in the engraving. On either side this corridor leads to a wider open balcony upon which the staircases and the elevator shaft that connect the floors open. The isolation of each floor is thus accomplished, there being no communication between the floors of the pavilions without first passing into the open air of the balcony. Each ward is provided with water-closets, lavatory, bath-room, nurse's day-room, linen closet, scullery, and closet for patients' clothing, none

of which communicate directly with the ward. In addition an isolating room, capable of receiving two patients, is provided for each ward.

In the basement of the service portion of the pavilion is provided a dining-room for convalescents, and a dormitory for servants, and an isolating room for maniacal patients. The basement corridor is continuous with the general corridor that connects all the buildings. A separate lift is provided, leading from the basement to the scullery of each ward. To this service portion of each pavilion is added a third story, in which is provided residence apartments for the hospital *internes*, also a small isolated ward for one patient and a laboratory room.

THE RECEIVING RESERVOIR OF THE WASHINGTON AQUEDUCT.

GENERAL M. C. MEIGS writes the following letter to the *Washington Star*:

"A statement is published that a late storm swept into the receiving reservoir of the Washington aqueduct the drainage of 36 square miles of surrounding territory. The same paragraph also states that the streams flowing into the reservoir drain about 10 or 11 square miles. The case is not so bad as reported. The actual drainage area of the valleys above the dam across Little Falls Branch, which creates this reservoir of some 56 acres, is about 4,000 acres, or 6 square miles, unless my memory of my original surveys greatly errs. I ran out the lines of watershed, and remember them quite positively as inclosing 4,000 acres. But man's memory is not always to be relied on after an interval of 34 years. But the storm-water of such a flood soon runs off through escapes provided for it, and the waters sent into the city are mostly from the Potomac, which itself drains some *thousands* of square miles. To cut an intercepting ditch around the margin of this reservoir will have a good moral effect, but it will not keep out of our city the drainage of many square miles of cultivated and uncultivated land. The upper end of the reservoir was originally excavated to a sufficient depth with intention that all deposits settling at the outlet of the stream should be periodically dredged out of the basin. This could be done for from 15 to 20 cents per cubic yard. But its necessity has been overlooked, apparently, by those in charge. There were means for allowing great floods to escape over the by-pass and outlet, and other means for drawing off, through the culvert under the dam, all waters that at any time appeared unfit for the city service. To carry all flood-water around the reservoir will require a large intercepting ditch. Houses below the dam have been swept away by the stream when angry. This happened during the work of constructing the dam."

ASPHALT AND CONCRETE FOOT PAVEMENTS.

IN the discussion following the reading of Mr. Strachan's paper on "Asphalt and Concrete Foot Pavements," published in our issue of August 13, we learn from the *Builder's* report that Mr. Vawser, of Manchester, mentioned the advantage which was experienced at Macclesfield by laying concrete footpaths in about 4-foot squares, and putting between each a piece of plank. It was found that the elasticity of the planking was sufficient to prevent any cracking.

Mr. Fowler, of Manchester, agreed as to the great value of concrete paving, which, seven years ago, he used for the Newcastle Cattle Market. There he placed a lath round the boundary of each section, and there was not a single crack.

Mr. Ellice Clarke, of London, said his experience of an asphalt footpath $\frac{3}{4}$ -inch thick was that at the end of three years it required very considerable repairs. The unsightliness of cracks in asphalt was their principal objection; they did not detract at all from its wearing well. The practice mentioned by Mr. Vawser had been discontinued by all who had had much experience of asphalt. Now it was usual to lay two slabs of concrete on alternate days, or two or three days.

Mr. Boulnois, of Portsmouth, said that some of the earlier samples of ferrumite stone had too much iron in them, and being thus too hard, had a very slippery surface. The secret of the wear of asphalt lay in a nutshell. Unless it got sufficient traffic upon it it would never consolidate properly.

Mr. Lemon, of Southampton, said that twenty years ago he was very enthusiastic about asphalt, and his Corporation laid a great deal of it down. He had come to the conclusion now that there must be a very large traffic over it, or at least sufficient to keep it together. Otherwise it was bound to fail. Some laid down $\frac{3}{4}$ -inch thick soon wore out, but some laid 2 inches thick in a roadway where there was great traffic had been down for fifteen years, and had never cost sixpence for repairs. With respect to concrete, he thought concrete made and laid *in situ* was the footpath of the future.

NEW YORK AQUEDUCT COMMISSION REPORT.*

THE Commission organized under the act of Legislature passed June 1, 1883, and the report gives a history of all transactions up to the close of the operations of last year.

The report of Mr. Spencer gives an account of the organization and changes in the Commission; of the public hearings and discussions; of the appointment of the Chief Engineer August 15, 1883; the adoption of plans and profile of location February 27, 1884, and of subsequent modifications, and of the award of contracts (three to Messrs. O'Brien & Clark, four to Brown, Howard & Co., and two to Heman Clark) for nine sections of the work on December 13, 1884. The expenditures for the year 1884 were \$185,760.63.

May 13, 1885, plans for the new gate-house at Croton Dam were adopted, and, July 30, the contract awarded to James S. Smith and Henry H. Brown. In the fall of 1885, and up to April 1, 1886, hearings were again held on the matter of the proposed Quaker Bridge Dam.

December 2, 1885, the conclusion was reached that the Sodom Dam and reservoirs should be constructed immediately.

The expenditures for 1885 were \$2,265,147.58.

February 17, 1886, resolution passed to line the whole aqueduct with brick.

January 28, 1886, the terminus of the New Aqueduct was fixed at the northerly side of the largest reservoir in Central Park.

October 15, 1886, the tunnel between shafts 0 and 1 met, the lines agreeing within $1\frac{1}{4}$ inches.

The expenditures for 1886 were \$5,029,684.21, the total to date for a period of three years, four months, and twenty-three days being \$7,503,310.32.

The first year of this time was spent in surveys, location, adoption of plans of construction, obtaining title to land, etc.

The leading dimensions are given as follows:

AQUEDUCT TUNNEL.

Length of tunnel and open cuts from Croton Dam to Harlem River to be.....	28 $\frac{1}{2}$ miles.
Length from the north-easterly shore of the Harlem to gate-house at One Hundred and Thirty-fifth Street and Convent Avenue.....	2 $\frac{1}{2}$ "
Total.....	30 $\frac{1}{2}$ "
Length of pipe-line from gate-house, One Hundred and Thirty-fifth Street gate-house, will be 12,525 feet, or.....	2 $\frac{1}{2}$ miles.
Total length of Aqueduct.....	33 $\frac{1}{2}$ "

Of this 22.65 miles was excavated January 1, 1887, leaving 8 $\frac{1}{10}$ miles to be excavated at that date.

SHAFTS.

Of these thirty-five were completed and three to be contracted for.

The greatest depth of shaft from surface was..	350 feet.
The least depth " " " "	28 "
Aggregate depth of shafts excavated.....	4,491 "
Average depth of the tunnel below surface. . .	170 "

The President hopes that the Sodom dams and reservoirs, to be known as the "East Branch Reservoir," will be completed before the close of the year 1888, as well as the Muscote Dam and Reservoir, and that these will be sufficient for present supply.

The Quaker Bridge Dam he leaves in abeyance for still further consideration.

Then follows the report dated March 7, 1883, made by Mayor Edson and the committee appointed by him on the question of supply and the urgency for large additions at the earliest practicable moment.

Then an exhibit giving the rules adopted for the selection and appointment of inspectors on the work.

The report of the Secretary comprises a classified statement of expenditures and a list of officers, and a complete list of the engineering organization.

The report of the Chief Engineer contains a succinct account of the work done under his charge. He alludes justly to the embarrassment likely to arise from the requirements in the Aqueduct law, that the plans, contracts, and specifications be submitted by the Department of Public Works; but that the courtesy of those in charge of this department had warded off unpleasant conflicts.

* Report to the Commission by the President, James C. Spencer, Esq. Containing reports of the Secretary, John C. Sheehan, and Chief Engineer B. S. Church.

He refers to the preliminary work and plans of Chief Engineer Isaac Newton, and their endorsement by him and other engineers of the Quaker Dam project. He mentions the public discussions, and then passes to the consideration of the New Aqueduct, giving a complete description of the final location, the letting of work, organization of force, etc.

He then considers the "Character of the Rock and Earth," "The Quality of Masonry Construction," "Supply from the Croton River," "Bids and Contract Prices," "Shaft Excavation," "Tunnel Excavation and Lining," "Contractor's Plant," and ends with acknowledgment of the services rendered by his assistants.

Then follow reports by Commissioner Hubert O. Thompson of August 8, 1883, submitting plans for the aqueduct, and September 11, 1883, endorsing the Quaker Bridge Dam.

The volume closes with tables of the (1) monthly rainfall in Croton Basin, 1870-86; (2) monthly and yearly flow of Croton River, 1870-86; (3) daily flow of Croton River for each month, 1870-86; Profile 1, rainfall and flow of river for each month, 1870-86; Profile 2, average monthly rainfall and flow, 1870-86; Diagram 1, storage required for daily supply of 250 to 400 million gallons; Table 4, analysis of bids on each section; Table 5, quantities and prices of contracts for each section; Table 6, list of contracts awarded; Table 7, shaft excavation, weekly and total progress; Table 8, tunnel excavation, weekly and total progress; Table 9, tunnel excavation, actual and required progress; Table 10, tunnel excavation, cubic yards excavated each month; Table 11, tunnel lining, lineal feet laid to January 1, 1887; Table 12, summary of work completed to January 1, 1887; Table 13, contractors' plant.

In addition to these tables there is a large number of photo-gravure pictures of the work at different points and different stages, of contractors' plant, etc.; also photolithographs of various details of construction, of methods of laying out, of head works at shafts, etc.

THE HEALTH OF NATIONS.*

EDWIN CHADWICK was born January 24, 1800; had his attention specially called to the value of sanitation in 1828; entered the public service as an assistant commissioner for inquiry into the poor-law system; became secretary to the first New Poor-Law Board in 1834, and a member of the Board of Health organized in 1848. In 1854, with the breaking-up of the Board of Health, he retired from active service, and since that time has been busy in writing on matters connected with sanitation and sociology. He is eighty-seven years old, yet within this year we have received from him a pamphlet on the "Elementary Education Question," and another on "Alternative Remedies for Ireland," showing that he is still active, and keenly appreciative of what is going on in the fields in which he is interested. He has been the main starting point of the sanitary work of the present century, and this in two ways. In the first place it is to Mr. Chadwick that we owe the statistical foundations which alone make it possible to put sanitation on a scientific basis. The earlier commissions of inquiry into the sanitary condition of the people of England were largely due to his efforts, and their reports are mainly from his pen. The organization of the system of registration of vital statistics of England is due to his advice. In the second place he has constantly acted as a powerful stimulus and influential guide to other workers by the incessant stream of reports, reviews, addresses, and pamphlets which he has been contributing to the press for over fifty years. Many of these have been anonymous; many have appeared over the names of men who had little to do with their preparation.

The story of his life and literary labors is therefore the story of the development of modern sanitary science, and Dr. Richardson has told the story very well, although in somewhat fragmentary fashion, which was perhaps a necessity. The keynote of all of Mr. Chadwick's teaching is the need for centralization and concentration of effort to obtain reliable data, to secure the best expert advice, and to provide for supervision of sanitary work by persons independent of local interests, and that all this is needed from a business point of view.

Every one who is interested in the social and sanitary problems of the age will find instruction in these volumes, which do not admit of summarization, so wide and various are the fields of inquiry and work which they cover.

* A Review of the Work of Edwin Chadwick. With a Biographical Dissertation. By Benjamin Ward Richardson. 2 vols. 8vo. London: Longmans. 1887.

RECENT SEWER CONSTRUCTION.

No. VIII.

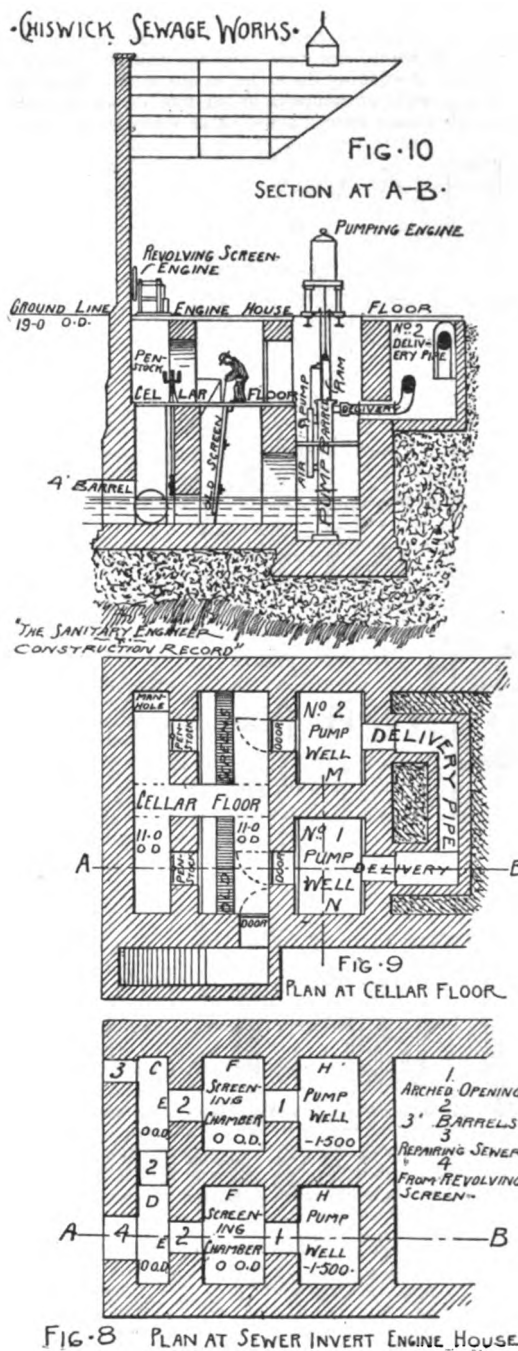

(Continued from page 327.)

CHISWICK SEWAGE-WORKS.

[Prepared for THE SANITARY ENGINEER and CONSTRUCTION RECORD by Joseph Hetherington, Resident Engineer.]

DURING the building of the new screen a temporary sewer was put in to divert the sewage. It is now closed with a penstock, and can be used at any time to divert the sewage when repairs are needed in the screen.

Where circumstances permit, it is desirable to have a bell-mouth both before and behind the revolving screen, so that no corners are left for grit and fine solids to accumulate; but at Chiswick the already existing pump-wells did not admit of this, and, accordingly, a 4-foot barrel takes the sewage from the wheel and conveys it into a chamber C D, Fig. 8, in the basement of the engine-

house. The repairing sewer also enters into this chamber. The chamber C D is divided by a wall, the object of which is not now apparent, as a 3-foot barrel is built in at the bottom of it. Penstocks E E admit the sewage to either or both engine-wells, H H, as may be desired, and on its way it passes through the old screens in the chambers F F, and through arched doorways to the wells, the floors of which are eighteen inches lower than the rest of the basement. A cellar floor is arranged eleven feet from the inverts, and on this the man stood when raking the paper, etc., from the grating. (See Section Fig. 10). The penstock-screws are on this floor and doorways to the pumps. The brickwork is very massive; all the walls are three feet thick up to the cellar floor and are built in cement. About six feet thickness of Portland cement-concrete is put in the foundations, much of it thrown in in bags, as the enor-

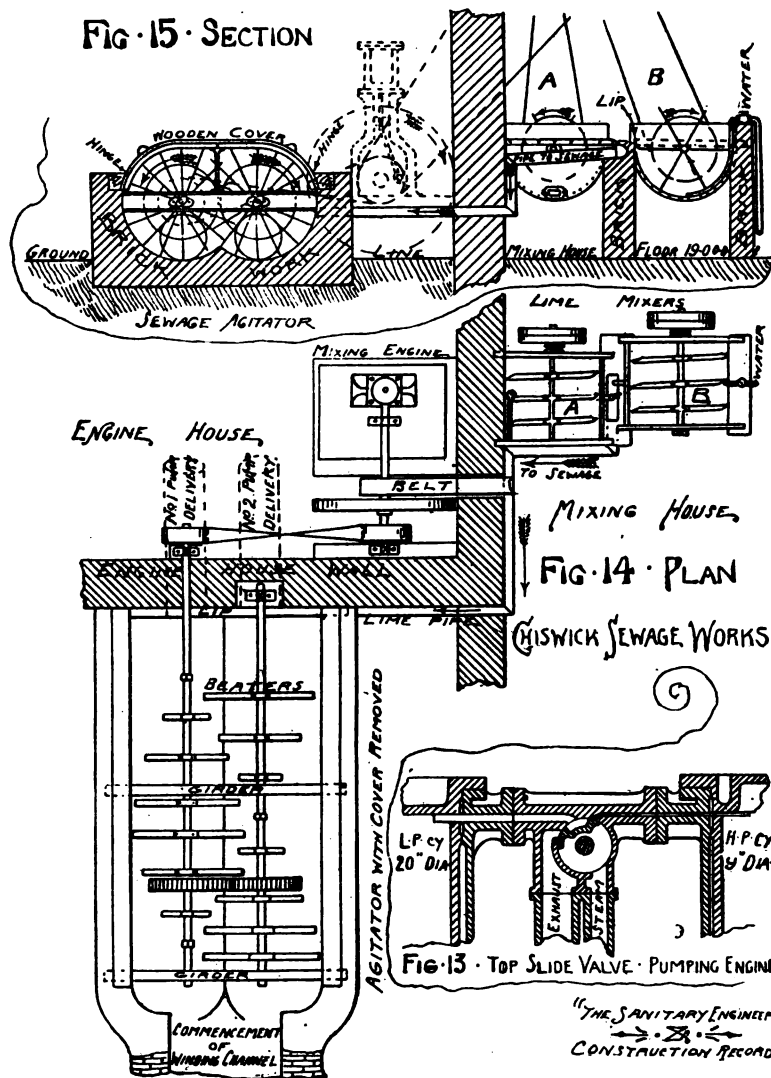

mous volume of ground-water washed the cement out before it had time to set in the ordinary way. The object of the wall immediately in front of the man with the rake, Fig. 10, is difficult to imagine. The wall is pierced with three arched openings, and its only conceivable service is to prevent collapse of the sides of the engine-house. The party-wall between the wells is carried up to the engine-house floor, and affords support for the girders on which the pumping-engines stand.

The engines and pumps are in duplicate and stand side by side and over the wells. This position will be seen from the plans in Figs. 8 and 9. In Fig. 10 the delivery-pipes are shown on their way to the winding channel. A section at M N, Fig. 9, showing No. 1 engine and pumps, is illustrated in Fig. 10, and a plan of the pumps in Fig. 11. The pumps are of the plunger and bucket type, worked by an inverted compound engine overhead. The action is as direct as it is possible to be, as the piston-rods go direct into the plungers. The pump-barrels are carried by girders built into the walls, and the engines on

girders at right angles to the lower ones. The brick-work is thus made an integral portion of the pumping machinery. Where the high-pressure piston is at the top of its stroke, the low-pressure piston is at the bottom, and the steam that is then under the high-pressure is expanded under the low-pressure piston as it makes its up-stroke. Similarly the steam from the top side of the high-pressure is expanded on the top side of the low-pressure piston, the relative positions of the piston being maintained by a light beam underneath, which is connected at each end by long links to the heads of the plungers. The condenser is underneath, between the pump-barrels, and the air-pump is fixed to the left-hand barrel in the figure, and operated by a cross-head on the side of the ram. The distribution of steam in the engine is effected by two circular valves; the top one is shown in section in Fig. 13, and the bottom one is exactly similar, but the other way about. The circular valve-chests are filled with steam, and the valve moving to the left admits steam to the high-pressure cylinder, and from the low-pressure cylinder to the condenser. At the same moment the lower valve shuts steam off the high-pressure piston, and allows the enclosed steam to expand into the low-pressure cylinder. On moving to the right

per minute, equal to lifting about 5,000,000 gallons of sewage with the two engines in 24 hours. Two shifts of men are employed at pumping and treating, but the actual work for one engine is only six hours in each 24 on the average, divided into four spells. There are, therefore, intervals of some hours duration when the flow is stopped, resulting in deposits in the sewers. Flushing-chambers are provided at the head of every sewer, but the immense quantity of filth scoured out by every rainstorm shows that these are unable to prevent the natural result of stagnation. Although the pumps are so much in excess of dry-weather flow, yet rainstorms occur when they are unable to lift the water at the rate it is coming down, and in dealing with the flow, diagrams will be given illustrating this. The storm-overflow can only act when the tide is down, and hence great power standing ready is absolutely necessary. The rational method would seem to be a small pump in addition, capable of dealing with the dry-weather flow when it is at its maximum, and also of being slowed down to the minimum. The sewage would not then stagnate, and the numerous complaints of stinking manholes would cease. Whenever the arrangement of pumps is at all like Chiswick the engine-wells should have a penstock between them, as well

the action of the valves is reversed. Motion is given to the valve-gear in part by the rocking-shaft on which the beam works, and in part by a cataract gear bolted to the side by the high-pressure cylinder. The section of valve in Fig. 13 corresponds to the position in Fig. 12, when the engine would not move at all. But by causing the cataract piston to move either to the top or bottom of its stroke (which can be done at will) the valves may be moved either to right or left, and either piston made to commence with a down-stroke. The cataract gear serves as a governor to the engines. The cylinders are steam-jacketed and covered with wood lagging. Steam is supplied by three Cornish boilers, each fifteen feet long and five feet six inches in diameter. The following are the leading dimensions of the engines and pumps:

Diameter of high-pressure cylinders	9 feet, length of stroke	3 feet.
" low-pressure	20 "	3 "
" pump-plungers	15 "	3 "
" buckets	27 "	3 "
" air-pump	8 "	3 "

The lift is 19 feet from the sewer invert to the floor of the mixing chamber into which the delivery pipes discharge. Each stroke up and down raises 90 gallons of sewage, and the engines can make about 20 strokes

as one between each well and the sewers, so that the sewage could be kept moving through the well of the engine at rest, and putrid stagnation be prevented. A small pump should also be connected to each well to rapidly clear out the water when it is necessary to go below. It is to be hoped, however, that few pumps stand in the sewage as they do at Chiswick, where the arrangement is unnecessarily filthy.

The pumped sewage is delivered into a brick chamber built against the engine-house, where the "milk of lime" is added and mixed with the stream. The milk of lime is prepared in two machines, A and B, to the right of Figs. 14 and 15. These are made of wrought iron, and are kept filled to an overflow lip with water. The water is admitted at the bottom, the lime is added at intervals, and the mixture stirred up by arms fixed to a shaft. By this means a continuous stream of milk of lime is discharged over the lip and conveyed to the chamber outside, where a second lip spreads it over the discharge from the pumps. This chamber is traversed by two shafts geared together, and carrying beaters of wrought iron two inches wide. They are caused to revolve about fifty times a minute, and they thoroughly incorporate the lime with the sewage. By their action the air is also brought into play as a purifier, for the sewage is beaten up into spray in which a rainbow may be observed on sunny days. The agitator outside is covered with wood to prevent splashing over.

(TO BE CONTINUED.)

PAVEMENTS AND STREET RAILROADS.

No. XIII.

(Continued from page 351.)

WOOD PAVEMENT IN THE METROPOLIS.*

Oxford Street, Marylebone Lane to Duke Street, was laid in September, 1876, upon an existing concrete foundation, at a cost of 13s. 6d. per square yard, and offered to be maintained for fifteen years at 12s. per square yard. It was repaired in 1878, and each successive year to November, 1882, when the blocks were removed, and the pavement relaid upon the plain system with a cement joint. The blocks originally were 6 inches deep, and when removed had worn down to about 3 inches, their actual life being about 6.20 years. The average annual wear of wood was 0.484 inch, which, reduced to the traffic standard, is equal to 0.319 inch. The pavement suddenly broke up and went to pieces at the end of 1882, owing, it is stated to water getting underneath, and the asphalt breaking up, which was probably caused by the "open joint" of asphalt and lime grout.

The Strand was paved in February, 1877, the cost being 13s. 6d. per square yard, and maintenance undertaken at 1s. per square yard for twelve years. Six-inch Baltic red blocks were used, and the pavement lasted till 1882, when it was renewed. The actual life of the wood was a little over five years, but it should be observed that the daily traffic is upwards of 1,100 tons per yard width.

Fleet Street.—The eastern portion was paved in July, 1877, the cost being 15s. per square yard. Considerable repairs have been carried out, but it is much worn, more so than Henson's pavement, and is somewhat bumpy to drive over; this may perhaps be partly accounted for by the gradient being sharp. The average annual wear of the wood is 0.456 inch, which, reduced to the traffic standard, is 0.251 inch.

Regent Street.—The portion between Piccadilly Circus and Vigo Street was paved in September, 1880, at a cost of 12s. 6d. per square yard, on a cement concrete foundation, 12 inches thick, formed of 2 parts of old macadam to 1 part of ballast. Six-inch deal blocks were laid, but they already show considerable signs of wear; in fact, they needed repair in 1883. The ascertained annual wear is 0.286 inch, which, reduced to the traffic standard, is equal to 0.384 inch.

Brompton Road.—The eastern part was paved in December, 1878, at a cost of 13s. 9d. per square yard. The blocks have been repaired on several occasions; the surface is in a more uneven condition than Henson's pavement, and the joints are much worn. The life of the blocks may be put at six and a half years. The ascertained annual wear is 0.373 inch, which, reduced to the traffic standard, is equal to 0.431 inch.

The author fails to observe that the asphalt bed and joint passes the merit claimed for them, and certainly the pavement in Brompton Road, the surface of which became irregular at least two years ago, is in an extremely unsatisfactory state, owing no doubt to the failure of the joint and quality of the wood.

Lloyd's patent "keyed" pavement was laid in Pall Mall in February, 1879, and, from the deplorable condition into which it had fallen in December, 1883, there can be little doubt that it has proved an utter failure. Unquestionably the work was carelessly executed, as the author found blocks varying in length from 8 inches to 15 inches, and joints from 1 inch to 2 inches in width; and when it is considered that the blocks were laid diagonally, although the wood used was pitch pine, it is not unreasonable to attribute the failure to the mode of jointing and diagonal form of blocking. The specimen blocks submitted were taken up in December, 1883, and they reveal the fact that the so-called "key" was no key whatever, it having entirely failed to hold the blocks together; and considering the irregularity of the width of the joint and the pooriness of the material with which it was formed, together with the uneven bedding of the blocks, it will be readily understood that the joints soon wore down, and that the blocks became rounded, thereby rendering the pavement uneven and more bumpy to drive over than any other modern system. The pavement originally cost 8s. 5d. per square yard only, being laid on an existing concrete foundation. When the blocks were removed they were about 4½ inches deep, but being so much rounded and unevenly worn, it was found that they could not be turned and relaid; consequently deal blocks upon the plain system were substituted. The life of a large area of the pitch pine "keyed" blocks was, therefore, less than five years—an extremely unsatisfactory result, especially when it is remembered that the carriage-way is extremely wide.

The same system of pavement was laid in the upper part of Regent Street in September, 1880, at a cost of 13s. 9d. per square yard. It was repaired in 1883, and again this year; it already shows considerable wear, and is uneven in places. The blocks are of pitch pine, 6 inches deep, and the ascertained annual wear is 0.214 inch, which, reduced to the traffic standard, is equal to 0.288 inch.

The pavement known as Carey's system was laid in Cannon Street in September, 1874, at a cost of 13s. 6d. per square yard, the maintenance terms being two years free and fifteen years at 1s. 6d. per square yard per annum. The blocks originally laid were 4 inches wide by 9 inches by 6 inches, and were shaped with alternate convex and concave ends, and laid on a thin bed of ballast, the joint being formed of lime grout. Considerable repairs and renewals have been carried out from time to time, and in

*A paper by George Henry Stayton, Assoc. M. Inst. C. E., and printed in the Minutes of the Proceedings.

March, 1884, the author saw several trenches opened near Queen Street, at which places the original blocks had worn to a depth of 3 inches, the surface being extremely uneven, not to say bad. The western section, which was renewed about a year ago, is already uneven, and begins to show signs of wear, and notwithstanding that the wood has considerable durability, yet, owing to the inferior surface of the pavement, the author would hesitate to class it among successful pavements.

The ligno-mineral pavement was laid throughout Coleman Street, City, in June, 1865, at a cost of 13s. 6d. per square yard. The paving consisted of mineralized pitch-pine blocks, 4 inches deep, with a "mastic" joint, the top portion being lime grout. The pavement having become worn out, owing to open joints and decayed wood, it was taken up in April, 1882, when asphalt was substituted. It is extremely probable that in consequence of the carriage-way being so much in the shade, the wood was specially liable to retain moisture. Fore Street was similarly paved in December, 1874, but the wood was replaced with asphalt in July, 1883.

Messrs. Moulem & Co.'s Pavement.—This plain system of paving has been laid in various parts of the metropolis, particularly in the city, St. Giles, St. Marylebone, St. Pancras, and Kensington. In Princes Street, Cavendish Square, blocks which were laid in September, 1874, are still in existence.

Kensington High Street.—In May, 1877, a section was laid near the Vestry Hall, at a cost of 14s. per square yard, with a three years' free maintenance. Six-inch blocks were laid in their natural state, with a ½-inch joint of lime grout. The present depth of the blocks is stated to be 3 inches, the annual average wear therefore being 0.440 inch. The surface shows considerable wear, and after rain water is retained at those points where it has worn below the channel-level. The latter evil is possibly to be attributed to the very slight rounding, one inch in four feet, to which it was laid. The blocks are to be renewed in October next, when the life of the wood will have been seven and a half years.

Fulham Road, Sydney Street to Arthur Street.—This section was paved in July, 1878, at a cost of 14s. per square yard, and in other respects was similar to the last-mentioned pavement. The surface is considerably worn, and the form of joint not only retains dirt but tends to round the blocks, the average depth of which is 4½ inches, or equal to an annual average wear of wood of 0.242 inch. The pavement will probably be relaid in 1885, when its life will have been seven years.

A large area of "plain" wood pavement has been laid in Kensington by Messrs. Nowell & Robson, who paved Kensington Road, Fulham Road, Uxbridge Road, and High Street, Notting Hill. The last-mentioned street was carried out in December, 1878, at a cost of 12s. 6d. per square yard, with a three years' free maintenance. The lime-joint gave much trouble shortly after the work was completed, and in places it may be observed that it has allowed dirt to accumulate. The average wear is equal to 0.218 inch per annum.

In other metropolitan districts besides Chelsea the local authorities have successfully laid a plain system of wood pavement by means of their own staff of workmen, particularly in St. Marylebone and Paddington. The credit of introducing this method is due to the St. Marylebone vestry, whose first work consisted in paving the portion of Oxford Street east of Regent Circus, in October, 1878. The blocks were laid upon an existing concrete foundation, and the work cost 8s. 4½d. per square yard, exclusive of the removal of the old stones. The blocks were repaired in 1882, 1883, and in 1884, at an approximate cost of 6d. per square yard. Plain yellow deal blocks, 6 inches deep, were adopted, with a cement-joint ½ inch wide, and they have worn to an average depth of 3.30 inches, but in some parts of the street the thickness is 1½ inch only. The surface shows considerable wear, and is uneven in places, the wood being so remarkably thin near the rests that it is a mere crust. The probable life of the wood is six and a half years. The average annual wear is 0.475 inch, and if reduced to the traffic standard it is equal to 0.306 inch. The heavy rate of wear is probably owing to the width of the joint, the author having taken up a piece of grout ¾ inch thick. This irregularity would have been avoided by the use of iron studs instead of temporary strips or latins. A large area was similarly laid in Edgware Road in October, 1880, and at the same cost. The surface is good; the annual wear is 0.198 inch, and if reduced to the traffic standard it amounts to 0.254 inch.

The Paddington vestry have laid 125,232 square yards in various streets. Praed Street was paved in July, 1879, with 6-inch plain yellow deal blocks, at a cost of 10s. 7d. per yard, and the surface is in a fairly good state. At the eastern end the blocks have been repaired on several occasions, the present depth of wood in the centre part being 4 to 4½ inches.

Generally speaking, the plain system appears to have given satisfaction, but the mode of jointing with lime-grout, or a wider joint than ¾-inch, cannot be recommended. Upon inspecting the lime-joint after a few years' wear, it may be ascertained that it wears below the surface, that dirt accumulates in the joints, and that the blocks have either become rounded or the top edges "burred," to such an extent that the surface has become bumpy. The lime-joint gave trouble when newly laid in Notting Hill in December, 1878, as after a sharp frost the grout, so to speak, "spewed" up, the rain filled the joint, and considerable sections of the pavement were literally afloat until the defects were remedied. A system

of blocking, which the author considers objectionable, is that by which the blocks of a new pavement are laid upon fresh unset cement floating, and, as the grouting is proceeded with, the blocks rammed with a "pavior's" rammer, so as to obtain a smooth surface. Under this process there is a probability of the blocks being injured or split, apart from which it is found that when the time arrives for renewing the wood, the surface of the concrete contains a series of indentations instead of being smooth and even. The difficulty may of course be surmounted by chipping off the projecting parts and refloating the surface, but the repaving cannot be so expeditiously or economically carried out. The result of the author's experience and investigation induces him to submit (1) that the surface of the concrete foundation should be perfectly smooth and fully set before the blocking is proceeded with, and (2) that a carefully-made cement-joint ¾-inch wide will not only be found simple and watertight, but will prove as durable as the wood itself.

Cost.—With the exception of a small area, the whole of the wood pavement in Chelsea, about 50,000 square yards, has been laid by the Board's own staff. The estimated cost of the pavements in King's Road and Sloan Street was 11s. 3d. per square yard,* but, as previously stated, the actual cost amounted to 10s. 6d. per square yard, exclusive of £120 spent in the before-mentioned experiments. The pavement in Fulham Road cost 10s. 3d. per square yard, the difference being partially attributable to the fact that a portion of the old broken granite was used in the concrete foundation in lieu of ballast.

The details of the cost per square yard, are as follows—viz.:

ITEM	31,313 yds. in Sloan Street and King's Road in 1879.	10,573 yards in Fulham Road in 1881.
Labor in breaking up macadam surface and excavating.	11.00	11.00
Cartage of old materials, including shoot for rubbish.	9.04	9.80
Portland cement for concrete and grout.	20.02	17.17
Thames ballast and sand for concrete, grout, and top dressing.	8.56	5.80
Blocks.	58.66	60.82
Studs.	1.58	1.48
Labor in bottoming up and leveling, preparing, and laying concrete, fixing studs in, wheeling, and laying blocks, grouting, top dressing, watching, and sundries.	13.45	14.12
Labor and materials in permanently filling in margins.	0.86	0.90
Sundries—plant, tools, superintendence, testing cement, oil, repairs, etc.	2.92	1.85
Total.	126.09	122.94

NOTE.—No allowance is made for the value of the paving stones and broken granite taken up and reused in other parts of the district, the minimum value of which amounted to £2,050, or about 1s. per square yard.

The variation in the prices paid for wood pavement in various parts of the metropolis has been somewhat remarkable, the maximum cost per square yard for laying a pavement and concrete foundation with entirely new materials having amounted to 18s. 6d., and the minimum to 10s. 6d. Owing presumably to competition and to the experience which has been gained, together with increased facilities, the cost has gradually been reduced to reasonable limits, as compared with the charges made eight or nine years since.

Management.—However excellently a street carriage-way pavement may have been constructed, its condition will soon become unsatisfactory unless its maintenance receives proper supervision. Good management implies not only that repairs shall be promptly and efficiently executed, but that the services of cleansing, watering, and sanding must be properly carried out; in short, the essentials of proper management are to be found in the judicious application of the scraper and broom, of water, and of grit, and in the immediate removal of defective blocks. The reinstatement of gas, water, and drainage-trenches must be classed under the first heading; and, although an apparently small matter, yet from the frequency of such openings, so serious an interference with the street surface is created, that in the course of a few years surface uniformity cannot be maintained unless this work is very carefully executed, and ample time allowed to elapse before the traffic is allowed to pass over the work. After a pavement has been laid for three years the existence of defective blocks becomes apparent, as by this time, the first effect of compression having ceased, the fibres of such blocks begin to yield under traffic pressure, with the result that slight surface depressions are formed. When this happens a bumping motion is created, and as the wheels then strike upon upon the edges of the adjoining blocks it is obvious that the surface must become irregular; and depressions or hollows a foot square or more are soon formed, which, unless promptly remedied, materially spoil the surface.

To avoid slipperiness and to insure many of the advantages claimed for wood pavement, it is essential that a thorough and systematic service of cleansing must be carried out, especially where macadam pavements are contiguous to wood, as in damp weather a considerable amount of mud is imported from them. In connection with the wood pavement in Chelsea there is a regular street orderly service, by which horse-droppings are removed and deposited

in bins. In addition thereto the wood pavements are washed once or twice a week, and are cleansed daily either by horse-sweeping machines or by hand labor. In the absence of heavy rains mere sweeping fails to keep wood pavement clean, and washing then becomes essential. To effect this water-vans are sent out before midnight, and the surface is so thoroughly soaked that, by the time the sweeping machines commence to work at 3 A. M., the dirt is easily removed, the entire operation being concluded in the forenoon. The ascertained cost of this service, including labor and horse hire in washing and sweeping, street orderly work, and collection and removal of the sweepings, amounts to 4½d. per square yard per annum, as against 11d. per square yard for macadam previous to the substitution of wood. It has been asserted upon good authority that the cost of cleansing wood pavement is very trivial; this is slightly misleading, the proportions being approximately:

Macadam	1.00
Wood	0.41

Theoretically, the amount of mud created upon the surface of wood, as also in the case of asphalt, should be almost nil; but practically the author finds that some 2,700 cartloads are annually removed from a length of about three miles in Chelsea. Therefore, after making every allowance for the conversion into mud of 350 loads of sand placed on the wood when slippery, it is obvious that a great portion of the mud is imported from the adjacent macadam.

The plentiful application of water prior to the work of cleansing is most beneficial, both in preventing dust, and, from a sanitary point of view, in removing the cause of obnoxious smells; but as the metropolitan water-supply is not yet in the hands of the ratepayers, its use for this purpose is materially restricted. The author ventures to assert that the system of cleansing thus described is amply sufficient to obviate slippery surfaces caused by the accumulation of greasy mud, and that the summer watering may be so carried out that a minimum wetting will suffice to keep down the dust. Letters have recently appeared in the *Times* with reference to the watering and cleansing of wood pavements, in which it has been strongly urged that such pavements should not be watered at all. When it is considered in what an unskillful manner street-watering is sometimes done, and that, owing to the stupidity or carelessness of carmen, considerable danger to locomotion is caused by overwatering a dirty pavement, there may be some justification for the contention. Doubtless horses travel better on dry wood pavement than on a watered surface, but in the absence of rain, watering is an absolute necessity for keeping down fine dust, more especially upon a hot windy day, when at least five or six wettings are required. Watering is also necessary for the preservation of the wood itself, as without water it would be materially injured by abrasion under such conditions. It is also questionable whether the very fine dust which must be given off under a non-watering system, would not become so serious as to be injurious to health and promote disease of the eye; but apart from this, the nuisance from the heat and dust combined would become intolerable.

In continuous damp and foggy weather and on frosty nights wood pavement is especially liable to become slippery; therefore, to insure a safe foothold for horses, its surface should be covered with a thin layer of Thames sand or grit. In Chelsea it has been found that this operation can be more expeditiously and evenly carried out by horse-machines known as "sand-distributors" than by manual labor alone. Night gangs have been organized, and, according to the conditions of the weather, the machines are sent out either at night or early in the morning; in the latter case the whole of the wood is sanded and made fit for traffic by 8 o'clock. The operation is beneficial to the wood itself, and might be advantageously carried out at other times, because the grit becomes so well worked into the ends or fibres of the blocks that it not only affords protection to them, but insures a better foothold for horses. The ascertained cost of the sanding does not exceed ½d. per square yard per annum.

SIXTH ANNUAL REPORT OF THE WATER COMMISSIONERS OF AMSTERDAM, N. Y.

THIS report, prepared by Mr. A. H. Degraff, Superintendent and Engineer, shows the present state of the works to be as follows: Total cost to date, \$371,221.52, with bonds outstanding for \$257,000. Expense account for the year (net), \$20,964.26, including \$2,921.80 for construction account, and receipts \$22,465.34. There are now 76,089 feet of distribution pipe in use and 2,050 were laid during the year. There are 130 hydrants, 196 gates, and 37 meters. The amounts metered varied from 6,508 gallons for the year to over 13,000,000 gallons, or an average of 128,770 gallons per day and an income of \$10.81 per day from meters.

The average cost for 864 feet 4 inches and 1,905 feet 6 inches pipe laid, including pipe, special castings, 7 stop-gates, six 4-inch and one 6-inch hydrant, freight handling, trenching, and back-filling, was 95 cents per foot.

In the autumn of last year the water was drawn down nine feet in the reservoir, and this with the proposed sewerage system makes an enlargement of the works necessary. Two plans are suggested, but the second, which proposes a large storage-reservoir on the creek above the present distributing reservoir, is recommended.

ENGLISH PLUMBING PRACTICE.

BY A JOURNEYMAN PLUMBER.

No. LXVII.

(Continued from page 139, Volume XV.)

HOT-WATER FITTINGS.

AFTER the boiler is properly fixed the next thing is to consider the circulation-pipes. Figure 1 is a sketch diagram showing how they are fixed in some of the London jerry-built houses. The pipes are usually of $\frac{3}{4}$ -inch bore, and of the gas-pipe description, which is very light in substance. The bends are often carelessly made and buckled in their throats, so as to offer serious impediments to the free flow of water through them. The pipes are rarely coated inside, or galvanized, to prevent oxidation, with the result that frequently all the hot water has to be run to waste, as it is so highly colored with iron rust. In some slightly better houses 1-inch bore pipes are used.

and in first-class work it is usual to fix $1\frac{1}{4}$ -inch galvanized iron or tinned copper pipes. The iron is what is called the lap-welded steam-pipe, and is very strong. The copper pipes have a lapped and brazed seam, but the last few years a great deal of patent seamless drawn copper tube has been used. Copper pipe should always be tinned when quite new and bright. When kept in stock for some time before being tinned, it is often found that the inside, which cannot be seen, do not get coated over the entire surface, patches of copper being left untinned.

Referring again to Fig. 1, A is the cold-water and B the hot-water cistern. C is a pipe connecting the two. The writer has frequently met with this stupid arrangement. In some other cases the feed-pipe has been connected as shown by dotted lines at D. Both of these arrangements are bad, as the hot water will sometimes work back into the cold-water cistern, rendering the contents into a heated state. This evil is more serious when the cistern A has to supply cold water to the sinks, etc. This can be prevented by fixing a light flap or valve on the end of the connecting pipe, as shown at H, Fig. 1, but, as this valve is liable to set fast, it is not a good plan.

In some cases a small feed-cistern is fixed at the side of the hot-water cistern, as shown at E, Fig. 1. This is a better arrangement, as it breaks the direct communication between the cold and hot water cisterns, but the blunder

is frequently made in fixing a $\frac{1}{2}$ -inch—in some cases a $\frac{3}{8}$ -inch—ball-valve in the feed-cistern. There is some little risk of damage to the boiler attending this arrangement. The low head of pressure on and the smallness of the ball-valve allows the water to dribble in very slowly, so that if a tap is left running, say into a bath, and another tap is opened at a level with the boiler, it is possible to empty the cistern-pipes, and boiler; and it need scarcely be added this is a very dangerous thing to do when the boiler fire is alight.

In some cases the draw-off taps have not been connected with the circulation-pipes, but to a separate pipe fixed from the hot-water cistern. This is not to be recommended, as in the case of a high house a long length of pipe would have to be emptied of the stagnant cold water contained in it before hot water could be drawn. And again, the pipe would have to be connected to the upper part of the hot-water cistern, the lower strata of water being often quite cold. This would limit the available supply of hot water. The writer has seen a few cases where the feed-pipe was fixed direct from the cold-water cistern to the boiler. In one case the pipe was only $\frac{1}{2}$ -inch in bore, which was much too small. The feed-pipe should always be so large that the cold water will run in as fast as the hot water can be drawn off.

Hot-water cisterns generally have steam-tight covers, or manholes, and have a pipe fixed from the top to the outer

FIG. 2

FIG. 4

air above the level of the cold-water cistern. In some cases this, what is commonly called expansion-pipe, is turned over the top edge of the cold-water cistern as shown at G, Fig. 1. In one case the writer saw several years ago, when the cold-water cistern was full the water covered the end of the expansion-pipe and the connection thus made created a circulation between the water in the two cisterns.

It is very important that all pipes connected to a boiler should be kept free from any stoppage, or a possibility of the water being frozen. There is no more frequent cause of boilers bursting than pipes being frozen. In some cases a patent plug, with a thin disk of copper in the centre, regulated to break when an extra pressure has been brought to bear, has been attached to the boiler. In other cases a safety-valve has been attached. Some of the safety-valves are similar to those usually attached to steam-boilers. Another kind much used is called a "dead-weight safety-valve," and is shown in section at Fig. 2.

The top of the inner tube is conical and ground into the outer cap. Weights A A A are added in proportion to the pressure the valve has to resist, care being taken not to add more than is really necessary. This valve should always be connected with the boiler by means of a separate pipe. If connected with the circulation-pipes, as is sometimes done, and common keyed bibb-faucets are used for

drawing off hot water, water-hammer in the pipes, caused by sudden closing of a cock, will sometimes cause the safety-valve to jump, so to speak, and allow a small quantity of water to leak out. This kind of valve is a very good one, and is preferable to some that have the weights piled on the top, making them top-heavy and more likely to leak if they should be knocked against or jarred.

It is an open question if safety-valves are to be trusted in cold countries, as it is possible the valve itself may become fixed if the water inside gets frozen.

Fusible plugs are sometimes fixed to boilers, so that if by any means, such as shortness of water or insufficient supply, they become empty when the fire is burning, the plugs will melt and thus relieve the pressure brought to bear by the sudden expansion of water into steam should it come in when the boiler is hot.

In first-class houses of modern construction the old way of fixing the hot-water cisterns at the top of the house, or on an upper floor, is not so generally practiced, but what is known as the cylinder system has been adopted.

Figure 3 is a sketch diagram showing one of the simplest arrangements as fixed in some of the middle-class houses. J is the boiler, K the hot-water cylinder, L the cold-water cistern, and M M M the draw-off cocks. In this system the water circulates between the boiler and cylinder and a pipe is fixed from the top of the cylinder and continued above the cold-water cistern. From this pipe branches and draw-offs are fixed in the various positions as necessary. The only drawback to this system is, that the water in the rising pipe being stagnant, and at times nearly cold, it has to be drawn off before hot water can be had at the cocks. In some cases a return-pipe has been fixed as shown by dotted lines, and as it was only necessary for the water to circulate slowly, this return-pipe has been fixed of a smaller size than the flow-pipe. For best work the return should always be the same size as the flow pipe, or the circulation of the hot water is very much impeded.

In some cases the hot-water chamber has been made of iron plates riveted to angle-irons, and made as shown in sketch, Fig. 4. But even when made of $\frac{1}{4}$ -inch iron plates it has been found necessary to have several stay-ropes inside to prevent the sides and top bulging out by the internal pressure. This bulging sometimes causes the joints of the pipe connections to leak, and it is nearly always the case that the manhole leaks. This manhole must, of necessity, be large enough for access for cleaning out the chamber, which is rendered more difficult by reason of the complication of stay-ropes inside.

The manhole-plate is of wrought iron and bolted over the manhole with a series of bolts tapped and screwed to an inside strengthening plate. Should the manhole-plate require to be removed for cleaning-out purposes, the bolts are generally difficult to get out by reason of their having rusted in. Sometimes the bolts break off and have to be drilled out, necessitating new bolts and retapping the holes for them. It is very rarely done, but it is better to have gun-metal or copper bolts instead of the iron ones.

(TO BE CONTINUED.)

SCHOOL-HOUSE AIR.

THE annual report of the Public School Department of the City of Hoboken, N. J., for the year ending April 30, 1887, contains a table of analyses of the air made in various school-rooms by Professor A. R. Leeds, upon which the Board of Education remarks that "while the sanitary condition of our schools is probably as good as the average of those of the neighboring cities, still the bad condition of the air in most of our class-rooms, as determined by Dr. Leeds' investigations, demands our earnest consideration and study," which is undoubtedly correct.

Taking the average proportion of carbonic-acid gas in the air of the streets, as found by analysis to be four parts in 10,000. Professor Leeds found that in School No. 1, in five class-rooms, it ranged from 15 to 29, in School No. 2 from 12 to 21, and in School No. 3 from 10 to 26 parts in 10,000. It is no wonder that in his remarks we find such notes as "Air of room unpleasant," "Air very close and disagreeable," etc.

In School No. 4 mechanical ventilation has been applied with benefit, as shown by the fact that in this school the proportion of carbonic acid ranged from 7 to 15 parts per 10,000. The cubic feet of air-space per scholar in the thirty-five class-rooms reported ranged from 265 to 65, being less than 100 in seven of the rooms. Such overcrowding as occurs in these seven rooms is utterly unjustifiable in a school-room under any circumstances.

HOT-WATER HEATING AND FITTING.

BY "THERMUS."

No. IX.

(Continued from page 324.)

LOSS OF HEAD OR PRESSURE BY ELBOWS OR BENDS.

THE loss of head in an elbow or bend should be divided into three parts in a study of the subject: (1) That due to change of direction of the water alone; (2) that due to friction alone, the same as in any pipe; and (3) that due to eddies and enlargements or contractions of the currents, such as exist when common screwed elbows are used that have pipes with square ends within them forming sharp shoulders against the current.

The *first* applies to all bends whose radius is less than five times the diameter of the pipe; but when the radius is five times or greater, with smooth bends the loss of head for change of direction becomes so small it may not be considered, as it practically becomes nothing.

The *second* (friction against the sides) applies to all bends, and, in fact, to all pipes, etc., without regard to shape, and it must always be considered as equal to the head consumed by the same length of straight pipe of the same diameter and character.

The *third* applies only to cases where the diameter of the bend or elbow is larger than the diameter of the pipe and has shoulders and threads, and it is greatest with square-ended pipes and least with pipes whose point of entry is easy, with the edges cut to a knife-edge and the angle of the side about as shown by Fig. 19½, and it does not exist at all in smooth bends of equal diameter throughout.

The *second* and *third* quantities, above mentioned, also apply to straight-screwed couplings or sockets and tees and

FIG. 21.

in them has about the same value as in elbows; but couplings being straight, of course, there can be no loss for change of direction.

The loss of head for change of direction alone in elbows differs with the angle. Weisbach's formula is the one most used, but it is difficult of application by practical men, and was presumably founded on the loss of head in fairly smooth bends in large water-pipe. If we had special fittings for hot-water work, somewhat like the Durham Co.'s special fittings for wrought-iron soil and waste pipes, in which the square ends of the pipes screwed against shoulders in the fittings, and with the diameter of the elbow or tee no greater than the pipe, then we could with considerable accuracy determine the loss of head by a bend or elbow, as we would have little more than change of direction and friction to consider; but with our present common elbows and tees reasonable approximations only can be formed. The late Robert Briggs was of the opinion that a common elbow (90 degrees), with a radius of about three-fourths the diameter of the pipe, would use as much of the head for change of direction as a pipe of the same nominal diameter thirty-eight diameters in length would use in friction while passing the same quantities of water or other fluid.

Deductions from the tables of Mr. Thomas Box also seem to confirm this, for what he calls "quick bends," or ones whose radii are about 1½ diameters of the pipe, or double the radii assumed by Mr. Briggs, give a resistance of about ¼ only (for change of direction) of what Mr. Briggs finds, and as this very nearly represents the ratio in which the resistance should decrease as the radii increased, we may reasonably assume that our common elbow will not use more head for change of direction than would be used by friction in 38 diameters long of the same pipe, and that this is the maximum. When the bend has a change of

direction of 45 degrees, or only one-half of 90, then the loss per change of direction is only half.

It might be well to mention here that though the loss for change of direction in two smooth 45-degree bends only equals the loss in one 90-degree elbow that the total loss in two ordinary 45-degree elbows is much greater than in

FIG. 22.

the one of 90 degrees, on account of the enlargements and contractions of the currents and the square ends of the pipes that a greater loss ensues from the nipping of two 45-degree elbows together than with one common elbow of 90 degrees.

The *second* division of the loss of head by elbows relates to friction only, and in that case the length of the bend through its centre line is taken and treated as so much straight pipe only.

The *third* division of the head lost by elbows is, as before stated, on account of the enlargement of the current when it enters the elbow and its subsequent contraction again to enter the pipe as it flows along.

There appears to be no question but that we should consider the action of the water in an enlarged bend nearly the same as when it leaves the boiler, and that a fresh point of entry, with its attendant loss, occurs each time. With favorable points of entry this third division of the head that is lost or consumed may be very much reduced, but with square ends there is as much of the head lost as is equivalent to ½ of the heads given in Table II., and this with very low pressures, such as is to be found in hot-water apparatus, is considerable.

On this subject Mr. Briggs considered that as much head was used at entry as was used by 58 diameters of the pipe, and about the same deduction may be drawn from a study of Mr. Box's tables for small diameter pipes.

If from all this, therefore, if we are led to take the extreme view of all the conditions, we are then bound to consider that a short common elbow uses as much head as 38 diameters of the pipe for change of direction alone, and that for entry, with ordinarily fitted square-ended pipes, we must add 58 diameters more, and it points to the fact that the total loss of head from all causes in a common elbow must be about equal to the loss from friction in 100 diameters long of the same pipe; at which rate a 2-inch elbow will consume as much head as 200 inches, or 16½ feet, of 2-inch pipe passing equal quantities of water.

This, of course, is a very extreme view of it, and the rule certainly will not hold true with large diameter pipes, though presumably we can apply it to all pipes smaller than 4 inches with common elbows.

With such diameter pipes and elbows as we ordinarily have to deal with in a heating apparatus, however, if we accept this as correct, we will be probably on the safe side and have something to spare when the radii of our elbows are no less than the three-quarters the diameter of the pipe (say a common elbow).

As the radius increases, however, the resistance decreases, so that in an elbow of 5 diameters radius, but otherwise a common screwed elbow, we have only the resistance to the entry of the water into the pipe, plus the loss by friction, to consider, which reduces the head consumed to be equal that lost by a straight pipe 62 diameters long.

If, on the other hand, we have a short common elbow, and take the trouble to ream the pipe ends carefully, we will then have (1) a resistance equal to the 38 diameters of the pipe for change of direction; then, in consideration of our easy point of entry, the latter (2) may be reduced very much below the value of 58 diameters given to it by Mr. Briggs, so much so that in thick pipes it may become practically nothing, and probably reducing the *total* resistance to less considerable than a pipe 50 diameters long will

give; as a perfect-shaped point of entry would reduce it to 38 diameters—plus something for friction, which even in a common elbow is less than four diameters of pipe will cause. Should the elbow be an ideal one, however, as shown in Fig. 21, then the first factor (for change of direction) is reduced to practically nothing, and the second is done away with altogether, so that friction alone remains and the resistance then is 7.8, or the length of the bend in diameters of the pipe, which reduces it to the same value as so much straight pipe.

To make this more comprehensive, we will make several diagrams of elbows and pipe, giving each part its value in diameters, and by diameters we mean the amount of head that would be consumed by a straight pipe one diameter long.

Let Fig. 22 be a common elbow with a radius of three-quarters the diameter of the pipe ($R = D \times .75$) with square-ended pipes entering it as shown. Then we will have 38 diameters for change of direction (C D) + 58 diameters for entry (E) + 4 diameters for friction = 100 diameters, as the value of an elbow joining pipes as in Fig. 22.

FIG. 23.

Let Fig. 23 be a common elbow, with a radius of three-quarters the diameter of the pipe—same as in Fig. 22—but with the ends of pipes entering it carefully reamed to an easy entry with a reamer, as shown in Fig. 19½ (last article); then we will have for a change of direction (C D) 38 diameters + nothing (or nominally nothing), for entry (E), + 4 diameters for friction = 42 diameters. If the pipe is not thick enough to ream until it gives the proper depth of easy entry, why, then, we must use our judgment and add something to the 42 diameters, and as the roughness of some uncovered threads in the fittings will always play some part in adding to the resistance, we may, perhaps, be justified in calling the value of Fig. 23, as a whole, 50 diameters.

The subject of Elbows will be continued next week.

(TO BE CONTINUED.)

Novelties.

Under this heading we propose to describe and illustrate appliances of probable interest to our several classes of readers. The selection will be made without reference to the wishes of agents or patentees, being governed solely by considerations of novelty, ingenuity, and probable interest to readers, and especially the fact that they have not been elsewhere described. As a rule we shall make no comments, and it is to be distinctly understood that a notice does not imply approval. No charge will be made for these notices, and any offer of pay for their insertion will insure their omission. We shall be glad to have our attention called to novelties suitable for this section.

PRESSURE-REGULATOR.

THE accompanying cuts illustrate a novel fluid pressure-regulator lately patented by W. B. Mason, of Boston, Mass.

The object of the apparatus, which is well known to engineers, is to prevent the rise of pressure above a predetermined maximum amount, and which is less than the pressure on the boiler side of the valve.

The improvements consist in the novel details of construction and arrangement of the parts employed, by which it is claimed the instrument is rendered more positive and certain in operation than others of its class generally in use, the prime object being to produce a valve that when in operation it will come into equilibrium in the position at which the amount of fluid flowing through should maintain it.

The valve is caused to move in each direction by fluid pressure, and not in one direction by a spring or weight, and in this is its principal difference.

Figure 1 is an elevation, partly in section, the parts being shown in the position assumed when no fluid is acting thereon; Fig. 2 is a longitudinal section on a plane at right angles to the plane of projection of Fig. 1.

The main body or valve-shell *a* of the instrument has the usual inlet and outlet openings, separated by a partition, which divides the shell into inlet and outlet chambers, and is provided with the passage or opening that connects the chambers, and which forms the valve-seat for the valve proper, *b*.

The valve when unseated is acted upon at its upper side by the pressure of the fluid in the inlet-chamber of the valve, and at its under side by the smaller pressure of the fluid at the outlet side of the valve, so that there is a tendency to seat the valve by the fluid-pressure acting upon it.

The valve-shell is provided with an extension below the outlet portion which is in free communication therewith. This extension forms a cylinder for the valve-actuating piston *c*, which is connected with the valve-stem, and is of greater area than the valve *b*, the proportion of these areas being about two to one. The upper surface of the valve-piston *c* is therefore exposed to the pressure of fluid in the outlet-chamber of the valve, which pressure acts in the opposite direction to that on the under side of the valve *b*, and is of substantially the same amount per unit of area, and consequently has about double the force tending to move the valve, so that the tendency of the pressure in the outlet portion of the valve acting on the upper surface of the piston *c* and under surface of the valve *b*, like that in the inlet-chamber acting on the upper surface only of the valve *b*, is to close the said valve.

Sections Showing Wooden Pipe Laid in N.Y. 85 Years Ago by the Manhattan Co.

The inlet-chamber of the main valve-shell is provided with a cap, containing a secondary or governing valve, *e*, controlling a port or passage, *f* (see Fig. 1), that connects the inlet-chamber with the cylinder, below the valve piston *c*. The stem of the valve *e* is acted upon by a spring *g*, connected with the valve-shell, the said spring *g* acting on a head or bearing-piece, resting on a diaphragm, *i*, directly over the upper end of the valve-stem, *e*, so that when unbalanced the spring forces the valve-stem and valve downward until the diaphragm and head come to a bearing on the upper end of the cap, as shown in Fig. 1, opening the valve *e* and permitting the fluid to pass from the inlet portion of the valve-shell through the port *f*, into the cylinder, where it acts on the under surface of the piston *c*. The valve *e* is kept up against the under side of the diaphragm *i* by a light spring. A pressure-chamber, *k*, is formed in the upper portion of the valve-shell, between the cap and the diaphragm, the under surface of which latter is thus exposed to whatever pressure may be in the chamber *k*, which pressure

pressure of which is to be regulated, and the spring *g* is so adjusted that when the pressure of the fluid to be regulated rises to the desired amount, the said pressure in the chamber *k*, acting on the under side of the diaphragm *i*, will be sufficient to overcome the force of the spring *g* and move the head far enough to permit the valve *e* to close.

The pressure of the spring *g* may be regulated and adjusted by a follower, acted upon by an adjusting device *n*, shown as a screw.

The dash-pot or cushioning piston connected with the valve is to prevent sudden movement, so that the valve will not chatter on its seat.

If the apparatus is used with a non-condensing fluid or gas, the dash-pot *p* may be filled with a liquid, or the regulating-piston *p'* have a tighter fit, so as to cushion on the gas.

THE MANHATTAN CO.'S OLD WOODEN WATER-PIPES ON BROADWAY.

WHILE the workmen of the Phoenix Construction Co., of No. 18 Courtland Street, New York, were opening Broadway on the west side between Courtland and Dey Streets, for the construction of the Consolidated Telegraphs Electrical Subway Co.'s conduits, they discovered the old wooden water-pipes of the Manhattan Company,

laid 85 years ago and through which no water had been carried for 50 years or so. These pipes were found about one foot below the cobblestones, and though no water had passed through them for nearly a half century they are remarkably well preserved in most places. They are white pine logs 13 to 15 inches in diameter, with a 4-inch bore through the centre, with hub and spigot ends as shown in sketch. In nearly all cases the rot has penetrated no further than 1½ inches, or through what is commonly called the sap-bands at the outside of the tree. In some places the bore is punky, but not to any considerable extent. The dark shading in the cross-section shows the rotten parts, and is a fair example of the preservation of the timber, the lighter parts being sound.

We know, of course, that timber in water lasts a long time, but in this case there was a subsoil of sand pretty well drained at the bottom, with the soakage of years passing through it occasionally from the surface.

When these pipes were in use the pressure in them presumably never exceeded ten pounds per square inch, and we are informed that the reservoir from which they conveyed the water was in the neighborhood of the Tombs.

E. G. LOVE, Ph.D., Gas Examiner.

A CORRESPONDENT of the Manchester (Eng.) *Guardian* gives the following causes which result in large gas-bills, and the remedies for the same:

"1. An escape of gas somewhere on the premises, which, being continued during the whole of the twenty-four hours till stopped, consumes more gas than many extra burners would do of an evening. 2. Incorrect registration of meter against the consumer. 3. Bad and worn-out gas-burners. 4. Increase of gas-pressure in the street-mains, which causes more gas to issue from, or rather be forced through, the orifice of the burner than is required for illumination. The remedy for each of these evils is in the hands of the gas-consumer, could that individual be led to take more than a casual interest in the gas arrangements of his house, shop, warehouse, or factory. The remedies, he says, are: 1. By regular inspection of his premises he can ascertain that there is no leakage, or remedy any defect of that

character. Whether any escape or not exists can be readily proved by turning on the gas at the meter when all the lights are turned off, and then noticing whether the small drum over the index is moving, or any registration of consumption is taking place. 2. By having his own dry meter, which can be examined by a competent and disinterested official for a mere trifle at any time. 3. By replacing gas-burners every twelve or eighteen months. 4. By having a properly constructed self-acting gas-regulator fixed on the supply-pipe from the meter. This will render him altogether independent of the pressure in the street-main, and by having a full supply of gas in his pipes at a uniform pressure he will both increase his illumination, be saved the constant expense and annoyance of breakage of globes, and that troublesome hissing of the gas which is so annoying; and to a certain extent it will purify the atmosphere by permitting the gas to be properly burnt instead of going off unconsumed."

DETLEF LIENAU.

DETLEF LIENAU, who died on Monday at the age of sixty-nine, was for nearly forty years an architect in New York City. He was born in Holstein, Germany; was educated at Stettin and at the technical schools of Munich and Berlin, and finished his architectural studies in France under Labrousse. He came to America in 1848 or 1850, residing in Jersey City, and practicing as an architect in New York. A few months before his death he took up his residence in the latter city.

Correspondence.

A BOOK ON WATER-SUPPLY OF TOWNS.

NEW YORK, August 22, 1887.

SIR: I shall be greatly obliged if you will inform me as to the best books on the subject of supplying towns and cities with water-works, or the best means of getting such information. Yours very respectfully,

S. W. ROWELL.

[J. T. Fanning's "Water-Supply and Hydraulic Engineering" is the best and, indeed, the only American textbook on water-supply. The chapters on water-supply in Philbrick's "Sanitary Engineering" give a layman a good idea of the problems to be considered, but the technical engineering details are to be found in Fanning's work.]

HOW TO DRESS IN HOT WEATHER.

WASHINGTON, D. C., August 21, 1887.

SIR: Apropos of your 20th August article on "How to Dress in Hot Weather," accept the following notes: Thermometers used, the ordinary thermometers in which the glass mercury tube is protected by a larger tube of glass as an envelope.

Thermometer A has a 5/8-inch naked bright bulb on south window-sill.

Thermometer B has black crape-covered bulb on south window-sill. C, outside north window-jamb in shade. The room is on the ground floor. House faces north and south, with window in north and south walls open and free circulation of air. Height of window-sill above tide, 95 feet.

Observations of heat of sunshine—1316 N. Street, W. Washington.

Sunshine thermometer, with bulb covered with black crape, placed flat on a southern wooden window-sill.

1887.	TIME.	SHADE. NORTH.	SUNSHINE. SOUTH SILL.	REMARKS.
July 12	1:15 P. M.	83°	131°	The sunshine thermometer is 95 feet above tide, laid on a wooden sill of a southern window, open to southern airs.
" 13	12:15 "	83°	132°	
" 16	1:20 "	97°	149°	
" 28	12:27 "	141°	
Aug. 4	1:17 "	121°	Difference between black crape-covered bulb and naked glass bulb about 10°.
" 9	12:30 "	80½°	146°	
" 10	2:20 "	85°	120°	
" 11	1:40 "	92°	137½°	
" 12	12 M.	80°	141°	11 A. M. to 11:17 A. M. and at 12 M. 147°.
" 13	12:45 P. M.	80°	146½°	
" 19	12:19 P. M.	84°	153°	
" 12	12:30 "	143°	
" 12	12:45 "	140°	
" 12	1:20 "	142½°	

These are the temperatures to which men in black hats and women wearing crape are exposed walking between noon and 2 P. M. on the sunny side of a city street without shade. The slightest haze lowers the record. It is highest with a clear blue sky.

M. C. MEIGS.

acts in opposition to the spring *g*, tending to raise the same, and permit the valve *e* to close. When, as in this instance, the regulator is to be used as a reducing-valve, the pressure-chamber *k* is connected by a port *m*, with the outlet portion of the valve-shell, or with any other place containing the fluid, the

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITIONS.

BOSTON.—Peabody & Stearns have been selected as the architects of the Syndicate Building on State Street. It is to be the largest fire-proof building in Boston. The same architects also have secured the "Fiske Building."

THE Hamilton, Ont., Coffee Tavern Company asks for plans and specifications of a building to be situated on the north-east corner of John and Jackson Streets, Hamilton, Ont., and offer the following prizes for same. For the plans considered best, \$100; for the plans considered second best, \$50. The plans and specifications to be the property of the company. The company does not bind itself to adopt any of the plans; but if any are adopted, the author may expect to be employed to superintend their execution. Plans should be sent, before September 15, to Alfred Powis, Secretary of the Company.

PLANS and estimates for the House of Industry, for the County of Welland, Ont., will be received by the undersigned until September 15. The sum of \$100 will be paid for the plan approved by the County Council. The building is to be located upon the Industrial Farm, one-half mile west of the town of Welland, Ont., and to be constructed of brick, 2½ stories high, exclusive of basement, heated by hot water and to furnish accommodation for sixty inmates. J. C. Page, County Clerk, Welland, Ont.

CAMBRIDGE, MA.S., PUBLIC LIBRARY.—The committee of the Council of Cambridge (of which Mayor Russell is Chairman), having in charge the proposed erection of a new public library building, received, on August 16, competitive plans from McKim, Mead & White, of New York, Peabody & Stearns, Van Brunt & Howe, William E. Chamberlain, and William P. Wentworth, all of Boston. The committee will not consider the plans until the last of September, and before any selection is made the approval of Mr. Frederick Rindge, now a resident of San Francisco (the principal donor of the library), will be required. It was intended to erect the building during the present year, but the committee has decided to postpone action until the spring of 1898.

PLANS and specifications are asked in competition from architects for a large hotel at Redondo Beach, near Los Angeles, Cal. It is to contain 400 rooms and to cost not less than \$100,000. The first premium is \$1,000. Plans should be sent in before September 20. Address Silent, Vail & McFarland, the Redondo Beach Company, First and Main Streets, Los Angeles.

MEETING OF WHOLESALE DEALERS IN PLUMBING AND STEAM SUPPLIES.

The Associated Dealers in Plumbers' Steam and Gas-Fitters' Supplies held their monthly meeting at the United States Hotel, this city, September 1. The association is in a prosperous condition and received numerous additions to its membership.

PROPOSALS.

TOO LATE FOR CLASSIFICATION.

REPAIRS TO PUMPING-ENGINES. (5,000,000 gallons capacity) for Toledo, O. Until September 20. Address the Board of Water-Works Trustees, H. C. Collir, Superintendent.

IRON DRAW-BRIDGE for the Americus, Preston, and Lumpkin Railroad, Georgia. Address at once, B. H. Hardaway, Chief Engineer, Americus, Geo.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE SANITARY ENGINEER AND CONSTRUCTION RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

For works for which proposals are requested see also the "Proposal Column," pages 371-372-385.

WATER. SEWERAGE. ETC.

MINNEAPOLIS, MINN.—The Minneapolis Water-Works Committee have agreed to erect a new pumping-house to accommodate four pumps, and advertise for two high-duty pumps 12,000,000 gallons capacity each, and 36-inch pipe sufficient to carry water a distance of 2½ miles.

PITTSFIELD, ILL.—Our correspondent writes: "An ordinance has been passed authorizing the expenditure of \$20,000 for water-works. Bids are advertised for to build a tower which will be 101 feet from foot of the foundation to top of the tank. Water will be raised to the tank by steam-pump. Bids are also asked for to lay the mains in front of all store buildings."

LE MAR, IOWA.—Our correspondent writes: "We have made no specific arrangements for water-works so far, but contemplate the erection of a system the coming year, if a satisfactory arrangement can be made."

FORT SCOTT, KAN. wants bids for constructing sewers.

CONCORD, N. H.—The extension of the water service for Penacook will begin in a few days.

NUNDA, N. Y., will have water-works. There will be a reservoir and pumps. The works are under contract.

CLARKSVILLE, TENN.—An agitation is started here for a supply of water from wells.

CAPE ELIZABETH, ME.—The report of the Water Committee has been received and acted on in town meeting. A vote will be taken next April on the proposition of the Portland Water Company. A. V. Cole is of committee for the April meeting.

HERKIMER, N. Y.—A village election was held September 1 to decide on water-works. The surveys have been made by E. D. Smalley, of Utica, who estimates the cost at \$48,200. We have not learned the result.

WASICA, MINN.—A supply of water for fire protection will be obtained from an artesian well.

ABERDEEN, DAK.—The Sewerage Committee has employed a civil engineer to prepare plans and estimates for a system of sewerage.

JERSEY CITY, N. J.—Several corporations and firms have proposed to the Bartlett Water Syndicate to furnish them their water by a supply, separate from the city, on the ground of the cost of the latter. No conclusion has been reached.

LYONS, ILL.—Address the Town Engineer with reference to water-pipe, etc., likely to be needed by the rapid growth of the town.

LARAMIE CITY, WYO.—Several parties are trying to make contracts with the city to supply earthen sewer-pipe.

NORTH PLATTE, NEB.—Work has just begun on the water-works for this place.

AUSTIN, ILL., together with Morehead, has it planned to obtain a supply of water from the recently organized Cicero Water, Gas, and Electric-Light Company.

OGDENBURG, N. Y.—Our correspondent writes: "Water-works were established in this city in 1868, and have been in successful operation ever since. The matter of improving the water by the introduction of the 'Hyatt Filter' has been under consideration, but has been indefinitely postponed by an adverse vote."

OAK PARK, ILL.—Incorporated is the Cicero Water, Gas, and Electric-Light Company to build water-works; Edwin S. Conway, P. W. Herrick, William M. Luff, incorporators.

DAVID CITY, NEB.—A city election, August 20, went in favor of raising \$22,000 for water-works. Work will be begun at once. The City Clerk will give information.

GIRARD, KAN.—Our correspondent writes: "Water franchise granted, but construction doubtful. No progress made."

JEFFERSONVILLE, IND.—The city has contracted with S. R. Bullock & Co. to build water-works, including necessary pumping-engines, a stand-pipe 150 feet high, and to lay about ten miles of pipe; the water to be taken from the Ohio River.

GREENVILLE, MICH.—Our correspondent writes: "I would say there will be a special election held on the fifth day of September to see if the people will bond the city for \$24,000 for water-works."

LAFRER, MICH.—Our correspondent writes: "The Common Council has submitted the question to the voters, whether to issue \$40,000 bonds to construct water-works; election ordered for September 12. It is believed authority will be given to construct the works."

MILWAUKEE.—There is \$48,000 available that the Council has appropriated for the new flushing-tunnel, to be cut through Dane Place, to pump the cold water of the lake into the river.

Fire apparatus and hose will be purchased for the Wauwatosa County buildings by the Committee. Chief Foley, of the Milwaukee Fire Department, acts with the Committee.

DAVID CITY, NEB.—Our correspondent writes: "A. A. Richardson, Consulting Engineer, Lincoln, Neb., will receive bids, until September 22, for constructing water-works at David City. Estimated cost, \$22,000."

DUBUQUE, IOWA.—A strong agitation for better sewerage is under way. City Engineer Tschirgi has prepared plans calling for \$128,000 to complete the system. Aldermen Byrne, Hayden, Trexler, Parker, and Doerfer are a special committee on the matter.

BUFFALO, N. Y.—The Board of Health urges the construction of sewers costing \$300,000.

HAMILTON, ONT.—A new 6-inch iron main and hydrants will be laid on Leeming Street.

BROCKTON, MASS.—With reference to sewerage, the special committee recommends the passage of the following order:

"Ordered, That the Committee on Department of City Engineer duly authorized by order of the City Council, approved August 16 last, to employ a civil engineer to make a survey of the city for the purpose of establishing a system of grades, etc., be and they are hereby further authorized and directed, in connection with said work, to cause to be made contour maps which shall exhibit the drainage area of North Main Street, Centre Street, and of the Packard Swamp section; the total sum expended for work named in this and the order before named, not, however, to exceed the sum named in said order."

ST. PAUL.—The Board of Public Works favors a sewer on Mackubin Street, from Canal to Ronds. Bids are to be advertised for a sewer on Earl Street, from Beech to Mound.

LAKE, ILL.—Our correspondent writes: "Nothing definite has been done in regard to the question of water-works for this town, but we hope to come to some conclusion before long, as the question is a very important one and we must settle it soon."

DEFIANCE, O.—Our correspondent writes: "Our city passed an ordinance August 17 granting a franchise to S. R. Bullock & Co., of New York, for water-works; time to accept franchise, 20 days from passage."

LAMAR, MO.—Our correspondent writes: "The city Board has entered into a contract for water-works, and the contract has been ratified by a vote of the qualified voters of the city. But I have my doubts if the company will erect water-works under said franchise."

BRISTOL, TENN.—Our correspondent writes: "The Board of Mayor and Aldermen of Bristol, Tenn., some two months ago appointed a committee to examine some plans offered said board and report back to said board. But the committee not being satisfied with any plans offered, have not yet reported, and I hardly think any thing will be done this season for water, but cannot say positively as to that."

WHITEWATER, WIS.—Our correspondent writes: "As yet there has been no official action by the Council in the matter of water-works, but the subject has been quite generally agitated among our citizens, and probably the Council will do something with it in the course of the next few weeks. When a system is put in it will not be owned by the city, but by the contractors, and operated on the annual rental plan. Any communications from contractors will now be in order."

Our correspondent encloses a copy of the Mayor's message, from which we quote:

"If we could get sufficient flow of water from an artesian well it would be the most desirable. I would recommend that the council appoint a committee to thoroughly investigate this water-works question and ascertain whether the citizens want water-works or not, and if so, to determine where we shall get the supply, the number of miles of mains required, and the system and plan of operation, etc. You could then make plans and specifications for what the city would need, authorize the receiving of bids for the same, and make a contract with the lowest responsible bidder.—Ed. Engebretson, Mayor."

JERSEY CITY, N. J.—Several new sewers are proposed. Address Alderman Hickey.

ALBANY, N. Y.—The matter of a pumping-engine is under consideration by the Water Commissioners.

POTTSTOWN, PA.—The Pottstown Gas and Water Company has decided to increase its bonded indebtedness \$44,000, to enable it to put down new water-mains and other improvements.

ST. LOUIS, MO.—The Mayor recommends enlargement of the water-works. A bill has been prepared for the matter.

FAIRBURY, NEB.—A. S. Strang has the contract for water-works, 5 miles of mains and 63 hydrants; annual cost to the city, \$3,000.

SAN FRANCISCO, CAL.—An 18-inch sewer is projected for Page Street.

BEACHMONT, MASS.—We last week noticed the movement for sewers. G. W. McLaughlin, H. T. Quinn, and T. S. Coffin are a committee to examine and report.

NEW HAVEN, CONN.—It is proposed that a new section of the Boulevard sewer be built. The work will probably be undertaken at once.

SCRANTON, PA.—Incorporated is the Valley Water Company; John Jermyn, E. E. Hicks, C. Jadione, and others.

SPRINGFIELD, ILL.—Considerable sewer-work is recommended by P. Haggerty, Inspector.

AUBURN, CAL.—Address F. Birdsall about water-works here.

COLUMBIA, MO., wants water-works, and has advertised for proposals.

AUGUSTA, GEO.—The Farmington Water Company will build works here.

PENNSYLVANIA WATER INCORPORATIONS.—The North Huntingdon Water Co.; the Penn Township Water Co.; the Fairfield Water Co.; the Bolivar Water Co.; and the Penn Borough Water Co., of Derry, E. Pitts, Murray Forbes, and J. K. Russell, Derry; C. S. Sims, Mt. Holly, N. J.; and J. C. Sims, Jr., Philadelphia, incorporators.

SANTA ANNA, CAL., has voted to raise \$50,000 for a system of sewers. Contractors should heed this.

WARE, MASS.—The agitation for sewers is active. Contractors and others should address the Road Commissioners.

TEMPLETON, CAL., has taken steps to obtain a supply of water.

WATER COMPANY.—Incorporated is the Los Guilicos, Cal., Water, Light, and Improvement Company; capital stock, \$250,000, divided into \$5,000 shares; directors, J. M. Donahue, N. W. Griswold, A. S. Rhorer, W. H. J. Matthews, and Henry N. Bird.

GLEN ELDER, KAN., is discussing water-works.

YORKVILLE, S. C.—The water-works question is being considered. Address G. N. O'Leary.

WEATHERFORD, TEX.—The city desires correspondence from water-works builders to erect water-works. A liberal franchise will be granted. Address M. E. Cameron.

SUMTER, S. C.—The contract to build water-works has been awarded to Jeter & Boardman, of Brunswick, Geo.

MORGAN, TEX.—Our correspondent writes in regard to water-works to be built by the Morgan Water-Works and Ice Co.: "We begin next week to bore for artesian well, from which source we will get a supply of water. After getting water, we propose to build a large reservoir and stand-pipe to hold the water, from which we expect to run water-mains through the principal streets, thus supplying water wherever needed. E. Winston is Secretary."

PONEROY, O.—Col. E. R. Davenport, of Charleston, W. Va., has been voted a franchise for building water-works. There will be 5½ miles of mains and 60 hydrants; rental, \$2,500 per annum.

GREENSBORO, N. C.—Surveys for water-works are made by E. W. Bowditch, C. E., of Boston, Mass.

MURRAY BAY, ONT.—A company has been formed to build water-works.

EAST TAWAS, MICH.—The Village Council desires proposals, until September 5, for constructing water-works, including about 37,000 feet of water-pipe, 4-inch to 14-inch, 23,000 pounds of castings, and pumping-engines with boilers, capacity at least 500,000 gallons daily. Will Mowray is Village Clerk.

LOS ANGELES, CAL.—The Lankershim Ranch Company has been organized to erect buildings, develop the needed water-supplies, and conduct a large ranch about ten miles from Los Angeles. J. B. Lankershim, L. T. Garney, C. W. Smith, and R. W. Poindexter are interested.

AUSTIN, MINN.—The contract for the Austin Water-Works has been let to the National Iron and Brass Works, of Dubuque. The price is \$36,000.

GAS. STEAM. BUILDINGS. ETC.

SALT LAKE CITY.—The contract for the construction of the U. S. Penitentiary has been awarded to the Pauly Jail Building and Manufacturing Co. of St. Louis, at \$48,000.

ST. PAUL, MINN.—Incorporated is the Brainerd Electric-Light Company; capital stock, \$100,000. Incorporators, John C. Rosser, William E. Seelye, Oliver H. Havill, all of Brainerd.

The Stillwater Gas-Light Company changed the name of incorporation to the Stillwater Gas and Electric Light Company, with a capital stock of \$60,000.

LOUISVILLE, KY.—The Union Gas Company has struck a great flow of gas on the fields 25 miles from the city. It is proposed to pipe the gas from Louisville.

PITTSBURG, PA.—Manufacturers of oil-main iron pipe should address the Western and Atlantic Pipe Lines, which will pipe oil from the Washington fields.

BOSTON.—A charter has been granted to the Union Gas-Light Company of Rockland. Jerome B. Poole, President; Albert Culver, Treasurer; capital stock, \$15,000, in 150 shares.

TOLEDO, O.—The Toledo Natural-Gas and Oil Development Company will develop its fields. Address Secretary R. D. Whittlesey.

LAKE, ILL.—The Economic Light and Heat Company asks for a franchise to lay gas-mains and furnish gas at \$7.25 per 1,000 cubic feet.

READING, PA.—Address William M. Kaufman, President of the Reading Steam, Heat, and Power Company, about furnishing the necessary plant. Addressed to the Board of Trade Rooms, 532 Penn Street, will reach him.

JANESVILLE, WIS.—Proposals for steam-heating apparatus in the Second Ward School building will be invited by the Board of Education.

SAN FRANCISCO, CAL.—The California Wharf and Warehouse Company filed articles of incorporation recently. The capital stock is \$250,000. The Directors are Robert Balfour, Robert Bruce, Park Fellows, Charles Page, and Charles P. Eells. The objects are to acquire land and buildings for the storage of grain and other articles of commerce.

ILLINOIS INCORPORATION.—Incorporated is the Sparta respecting Company at Sparta, capital stock \$3,000, to prospect for gas, oil, salt, and other materials; incorporators, W. R. Borders, S. W. McGuire, W. J. Lyle, and others.

ASHLAND, WIS.—The County Commissioners will receive bids for a \$20,000 jail.

WINONA, MINN.—The County Commissioners have ordered advertising for bids for the construction of a new court-house. Architect Maybury will prepare plans. The cost will be \$100,000.

ST. PAUL, MINN.—The Minnesota Natural-Gas, Oil and Fuel Company. Capital stock, \$1,000,000. Incorporators: William P. Sergeant, Robert M. Todd, Edward S. Prentice, Thovold V. Knatvold John P. Hovland, Charles C. Dwight, William McAdam, James H. Parker, D. F. Morgan, all of Albert Lea, where the place of business is to be located.

YAZOO CITY, MISS.—The city intends to bore one or more artesian wells.

RESACA, GEO.—A bill to incorporate the Resaca Canal and Manufacturing Co., of this place, with a capital stock of \$50,000, is now before the General Assembly. The firm contemplates to cut the canal, erect buildings for manufacturing purposes, and operate various kinds of industries.

KNOXVILLE, TENN.—The Knoxville Natural Gas Company will sink a large well. The American Well Drilling Company, of Louisville, R. Carroll, President, has the contract.

TOPEKA, KAN.—Organized is the Natural Gas and Mineral Exploring Co.; D. T. Paine, President; M. S. Evans, Secretary.

SAN FRANCISCO, CAL.—Incorporated is the California Cold Storage Company; capital stock, \$1,000,000, divided into 5,000 shares; directors: W. R. Smedberg, James O. Cashin, L. J. Harrison, Reed Jones, and D. M. Cashin. The company is formed to store and preserve fruits and vegetables.

BOSTON.—The Superintendent of the Lamp Department of Boston received proposals Thursday, September 1, for furnishing gas for a term of three years in the suburban districts, known as West Roxbury, Jamaica Plain, Brighton, Dorchester, South Boston, East Boston, and Charlestown. Each lamp is required to burn 3,228 hours in each year. The bids were as follows: East Boston Gas Co., \$1.65 per 1,000 feet; South Boston Gas Co., \$1.65; Dorchester Gas-Light Co., \$2; Jamaica Plain Gas Co., \$2; Charlestown Gas Co., \$1.65; Roxbury Gas Co. for burners of more than fifteen feet per hour, \$1.30; all others, \$1.65; Brookline Gas Co., large burners, \$1.85; all others, \$2. The contract was taken under advisement.

FORT SMITH, ARK.—The Fort Smith Natural-Gas and Power Company, capital \$50,000, will sink gaswells. H. E. Kelly is President, J. H. Cornell, Vice-President.

ERIE, PA.—The Presque Isle Natural Gas Company has closed a contract with the Buffalo Oil Company, of Lima, O., to bore a deep well. The cost will not exceed \$12,000.

BRIDGES.

MINNEAPOLIS, MINN.—Bids are asked for on the Marshall Avenue and Lake Street bridge. J. S. Senoll, of St. Paul, is the Engineer; S. A. Condit is Secretary of the Bridge Commission.

BOSTON.—The contract for the masonry and piers for the Harvard Street Bridge has been awarded to Messrs. Shields & Carroll.

BOSTON.—The building of a new caisson for the dry-dock at the Charlestown Navy Yard, for which \$31,000 was appropriated by Congress, has been abandoned. The lowest bid received was from the Atlantic Works, and the figures were about \$4,000 more than the appropriation. It has been decided to reconstruct the old caisson, using the frame, and for this purpose it has been towed into the dry-dock. To refit, the expense will be a matter of \$10,000 or more.

MONTGOMERY, ALA.—The South and North Railroad Company will build an iron bridge over the Alabama River, to be finished January 1. Construction is begun.

THE Missouri River Bridge and Iron Co. have been awarded the contract to build a bridge at Denver. Cost \$25,850.

WILMINGTON, VT.—The Vermont Construction Co., of St. Albans have been awarded the contract to build an iron bridge over the Winooski River.

CHATTANOOGA, TENN.—The Chattanooga Bridge Company has signed a contract with the Decatur, Ala., Bridge and Contracting Company, by which the latter agrees to construct a bridge for \$108,000.

SAN FRANCISCO, CAL.—A railroad bridge will soon be undertaken over Carquinez Strait, near Vallejo Junction.

CINCINNATI, O.—On September 10 bids will be received by the Commissioners of Hamilton County for constructing an iron bridge on Dick Road in Crosby Township; also a bridge in Sycamore Township. Address Fred Raine, County Auditor.

CINCINNATI, O.—The County Commissioners propose to erect a bridge on the road from Montgomery to Hinghaus.

PEORIA, ILL. (Special).—A special election was held August 30, for the purpose of obtaining the sentiment in regard to the construction of a new free bridge across the Illinois River. About half an average vote was polled, and it was practically unanimous for the bridge. The structure will cost about \$50,000.

ALBANY, N. Y.—Proposals will be received by the Superintendent of Public Works until Tuesday, September 13, at 12 o'clock, noon, for building iron bridges, abutments and approaches over the Erie Canal, at Hudson and Austin Streets, in the city of Buffalo. James Shanahan, Superintendent Public Works.

OREGON CITY, ORE.—Plans for a suspension bridge over the Willamette River have been prepared. The span will be 475 feet.

STREET WORK AND PAVING.

MINNEAPOLIS, MINN.—The improvement of Franklin Avenue, from Thirteenth Avenue to the river, has been decided on by the Street Commission.

MINNEAPOLIS, MINN.—T. M. Bohan, Philip Beck, John McGowan, and H. E. Blaisdell are on a committee to look up a site for a new park.

CINCINNATI, O.—The Board of Public Affairs is asking bids on paving and other work for Crawfish Creek Road.

BOND HILL, O.—E. F. Layman, C. E., of Cincinnati, has made plans for grading, macadamizing, etc., for certain streets.

MT. AIRY, O.—Plans for street-works, with drains, etc., have been prepared by A. A. Brasher, of Cincinnati, engineer.

JERSEY CITY, N. J.—Considerable street-work will be done, including improvement of Manhattan Avenue from Central to Sherman Avenue; sewerage Webster Avenue and Hancock Avenue.

OAKLAND, CAL.—Street-work, including sewerage with vitrified pipe, will be done on Tenth Avenue. Address J. W. Tompkins, Superintendent of Streets. Similar work will be done on Hannah Street.

FOND DU LAC, WIS.—The contract for paving Main and Forest Streets has been given to L. Schoenland, the lowest bidder, at \$1.13½ per square yard.

FORT WAYNE, IND.—Joseph Derheimer has received the contract for paving Calhoun Street with cedar blocks at 98 cents per square yard.

TORONTO, ONT.—has under consideration a by-law appropriating \$400,000 to harbor improvements, etc.

SYRACUSE, N. Y.—The City Engineer will advertise for proposals for paving and gutter-work, and for paving material and pipe-sewer.

SAN DIEGO, CAL.—Address Bernard King, Superintendent of Streets, about improvements on C Street and others.

ALLEGHENY, PA.—Charles Ehlers, City Engineer, can give information about the proposed improvements of Strawberry, Gane and Ashton Streets.

TRFNTON, N. J.—Grading, etc., on Lawlerton Avenue. C. C. Haven, City Surveyor, will give information.

CINCINNATI.—Bids are asked for by the County Auditor for improving the county road from corporation line to the village of Reading.

TOPEKA, KAN.—The City Engineer will make plans and specifications for the approaches of the Sixth Avenue viaduct.

CINCINNATI, O.—The Board of Affairs wants proposals for grading, flagging, etc., of Fern Street. Thomas G. Smith is President.

SAN DIEGO, CAL.—It is settled that the paving and sewerage of Fifth and Sixth Streets will soon be undertaken. John G. Capron, contractor, has already offered to do the work under bonds for \$100,000.

TOLEDO, O.—Bids are wanted until September 12 for macadamizing Infirmary Road. Address Charles A. Vordtriede, County Auditor, Toledo.

MINNEAPOLIS, MINN.—Contracts for street work have been awarded by the Public Works as follows: Grading Goodrich Avenue, for \$5,150, to James Keating; grading Summit Avenue, for \$11,845, to Murnane & Keough; grading Hamline Avenue, for \$3,104, to Murnane & Keough; grading Milwaukee Avenue, for \$7,000, to Kuhr & Bahr; sewer on Fillmore Avenue, for \$1,850, to McArthur Bros. The assessments for slopes on Maud Street and grading Dearborn Street were adjourned. The assessment for condemning and taking an easement for a sewer along the right of way of the St. Paul and Duluth Railroad Company was completed, and the clerk directed to give confirmation notice, and the assessment for widening Cliff Street was corrected and confirmed. Correction was ordered on the assessment for paving Wabasha Street.

TOPEKA, KAN.—Address the City Engineer about paving on Quincy and Jackson Streets, North Topeka.

RAILROADS, CANALS, ETC.

CHILLICOTHE, ILL.—Incorporated is the Chillicothe Street Railway Company. Lewis S. Hoyt, W. M. Mead, J. P. Laurie, and others.

ST. PAUL, MINN.—The North Dakota and Pacific Railway Company has been incorporated to build a railway from some point in Norman County to a point in Dakota, the route to be selected by the directors. Principal place of business, St. Paul. Capital stock, \$2,000,000. Incorporators: Charles G. Lawrence, Harris Richardson, Louis E. White, Joseph T. Avery, Walter J. Trask, all of St. Paul.

ST. PAUL, MINN.—Incorporated is the Duluth Terminal Railway Company, to operate a line or lines of railway along the shores of Superior Bay and St. Louis Bay in St. Louis County. Capital stock, \$2,000,000. Incorporators: G. G. Hartley, Alonzo J. Whiteman, William W. Billson, William F. Phelps, R. S. Munger, Josiah D. Ensign, Charles E. Shannon, M. R. Baldwin, J. H. Triggs, Luther Mendenhall, Asa Dailey, C. H. Graves, Alex. McDougall, Jacob R. Myers.

MOBILE, ALA.—Incorporated is the Mobile, Hatesburg, and Jackson Railroad Company. Capital \$300,000. A. Austill and others are incorporators.

MORRISVILLE, N. Y.—On August 20 the Canastota, Morrisville, and Southern Railroad Company was organized. Work will begin this fall.

SAN MARCOS, TEX.—A new line of railroad is being surveyed from San Marcos to the Pandale Railroad.

CANAL.—Superintendent of Public Works Shanahan opened bids August 21 for the enlarging of locks 8 and 48 on the Black River Canal, and has awarded the contracts as follows: Lock 8 to Thomas H. Stryker, Rome, for \$10,508.50; lock 48 to James E. Flood & Co., Sandy Hill, for \$9,895.50.

MILWAUKEE.—Twelve surveyors of the Wisconsin Central line are at work on the proposed railroad extension from Rib Lake to Tomahawk, Wis.

The Chicago, Milwaukee and St. P. R. R. Co. will build an extension from Geneva Lake and Milton Junction to Libertyville.

The Chicago and N. W. R. R. Co. will extend their tracks from Lake Geneva to Fontana and on Harvard Junction.

NEW YORK CITY.—The Dock Department has plans ready for docks from One Hundred and Fifty-Ninth Street to High Bridge. Other piers also are to be built.

PEORIA, ILL.—On October 11 a meeting will be held to consider the connecting of Lake Michigan with the Mississippi River by canal.

BLOCK ISLAND, R. I.—The Town Council of Block Island has contracted with S. V. R. Hendricks, of Easthampton, Mass., to open the Great Salt Pond on the west side of the island to the sea by a channel twenty-five feet wide and four feet deep at mean low water. Piles are to be driven on either side of the channel for 300 feet and on one side there is to be 500 tons of rip-rap stone leading out into the ocean to protect the channel from drifting sands. The channel will have a depth of seven feet and one inch at high water. The town appropriated for the work \$10,000, \$8,550 of which is given to the contractor, the work to be begun on or before the 30th of September and is expected to be completed on the first of January.

ROCHESTER, N. Y.—The Rochester Cable Railroad will build a line, involving much work of track-laying, etc.

LOS ANGELES, CAL.—An electric street railroad is projected by J. H. Brook, Hervey Ludley, and C. E. Day. The Julian motor will be used.

SAN DIEGO, CAL.—A street-car line will be built by George H. Crittenden and Frank I. Johnson.

CHATTANOOGA, TENN.—The Chattanooga Southern Railroad Company proposes to build from Chattanooga to the Tennessee line. Capital, \$1,000,000.

NEW ORLEANS, LA.—The only bidder for constructing the first section of the Diamond Island Bend Levee (200,000 cubic yards of earth-work), was Peter Trezant, at 25 cents per cubic yard. The Board of State Engineers recommended that the contract be awarded to him.

DULUTH, Red Wing and Southern Railway Company will be built to River Falls at once.

SISKIYOU, CAL., will vote on raising \$85,000 for six miles of railroad.

ISHPEMING, MICH.—The contract for the extension of the Chicago and Northwestern Railroad from Ishpeming to Republic, Mich., with a branch to Michigamme, was let, August 25, to Langdon & Co., of Minneapolis, railroad contractors. The survey is nearly completed, and a very large force of men will be put at work immediately. Langdon & Co. will complete the line of the Minneapolis, Sault Ste. Marie and Atlantic Railroad from Minneapolis to Manistique, Mich., this season.

LOUISVILLE, KY.—J. R. Serpell & Co. have received contract, and will build ten miles of very heavy work on Lynchburg and Durham Railroad.

WATERWAYS.—A convention of those interested in Western waterways will be held in Memphis, Tenn., October 20 and 21.

CLEVELAND, O.—It is proposed to consolidate the existing street-car lines and then build extensive additions, constituting a belt line. Address George Multern, of the Woodland Avenue and West Side Railway.

PHILADELPHIA.—The contract for grading the extension of the Reading Railroad from Glassboro to Mullica Hill has been awarded to Frank Thomas, of Shippensburg, Pa., and work is to be commenced immediately. The road will cost \$85,000.

BETHLEHEM, PA.—The Lehigh and Lackawanna Railroad will be extended from Wind Gap to Stroudsburg, in Monroe County. The contract for the first section of five miles, from Wind Gap to Saylorsburg, has been let, and work will begin on Monday.

EASTON, PA.—The Electrical Railway Company has given the contract for the line to College Hill to the Datt Company. Work will be begun at once.

MILWAUKEE.—The Chicago and N. W. R. R. Co. have let the contract to build forty-four miles of railroad in Michigan from Metropolitan to Republic to Langland & Co. of St. Paul.

The Cream City Railroad Co. will extend its track on North Water, Brady, and Racine Streets. Steel rails have been ordered.

The opposition to the cable roads here is dying out, and West Siders are anxious now to have them built and have notified the City Clerk to that effect.

GOVERNMENT WORK.

MANCHESTER, N. H.—Synopsis of bids for labor and material required to complete the building ready for interior finish for post-office, Court-House, etc., opened August 22, by the Supervising Architect:

Oliver S. Giddings, \$138,950, Concord granite; course; No. 8 cut.

Head & Dowst, \$127,785, granite, Sargeant & Sullivan, Concord, N. H.; course; as per specification.

Creedy & Noyes, \$127,705, granite, Railway Bay Concord; course; as per specification.

Mead & Mason & Co., \$110,578, granite, Concord; course; No. 8 cut.

Clinton G. Smith, \$124,448, marble, Sutherland Falls; as wanted; as wanted.

Clinton G. Smith, \$120,448, granite, Concord; as wanted; as wanted.

Sargeant & Sullivan, \$131,000, granite, Concord; course; as per specification.

MANCHESTER, N. H.—All bids for constructing the Government Building here have been rejected by the Supervising Architect of the Treasury, as being too high. The specifications have been changed, now calling for brick with stone trimmings in place of granite, and new proposals are asked for.

BOSTON, MASS.—The following bids for removing Babson's Ledge, Gloucester Harbor, to 14 feet at low water, were received by Col. G. L. Gillespie, August 30:

W. D. Duncan & Nickerson, 105 Atlantic Avenue, Boston, Mass., \$14.75 per cubic yard.

Thomas Symonds, Leominster, Mass., \$21 per cubic yard.

Charles H. Edwards, 35 Hawley Street, Boston, Mass., \$59 per cubic yard.

SYRACUSE, N. Y.—Synopsis of bids for steam-heating and ventilating apparatus for court-house, etc., opened August 25, by Supervising Architect:

Pierce, Butler & Pierce Mfg. Co., \$21,500, Reed's; fan, as specified.

S. I. Pope & Co., \$17,190, Crane; fan, 54 inches as shown, No. 188.

E. P. Bates, \$18,500, Reed's; fan, Blakeman, 7 feet 6 inches diameter.

West Point Engine and Machine Co., \$13,089.24, Bundy direct; fan, Buffalo blower.

Hartlett, Haywood & Co., \$16,306, vent-tube, own; fan, Exeter or Sturtevant.

Edward Joy, \$19,990, Walworth; fan, 72-inch Blackman.

SYRACUSE, N. Y.—The contract for steam-heating apparatus in the Government Building here has been awarded to the West Point Engine and Machinery Co., of West Point, Pa., at \$13,089.24.

POST-OFFICE, etc., Concord, N. H.—Synopsis of bids for joining, plastering, etc., opened August 27, by the Supervising Architect:

L. D. Willcutt, \$32,452; additional flooring, 15c. per square foot.

Mead, Mason & Co., \$27,200; 10c. per square foot.

John Moore, \$24,150; 12c. per square foot.

SYNOPSIS of bids for iron-fence work, Marine Hospital, Baltimore, Md., opened August 29 by the Supervising Architect of the Treasury: Joseph Norwood, \$2,085; Chester B. Albree, \$1,070; Van Dorn Iron Works, \$1,888; Champion Iron-Fence Co., \$754.82; J. E. Bolles & Co., \$821.82; George H. Pagels & Sons, \$1,225.

SYNOPSIS of bids for stairs at Peoria, Ill., opened August 24, by Supervising Architect: Poulson & Eger, \$6,550; Champion Iron-Fence Co., \$4,475; The Winslow Bros. Co., \$4,350.

BOSTON, MASS.—Colonel Gillespie has submitted during the past fiscal year the following estimates for necessary work during the coming fiscal year: Extension of sea-wall, George's island, \$10,000; extension of sea-wall, Galloupe's island, \$7,500; extension of sea-wall, Long Island, \$3,000; work on sea-walls, south end, east bluff, Governors island, \$80,000; widening main ship channel at upper middle, \$250,000; completing Fort Point channel, \$60,000; widening and deepening Nix's mate channel, \$25,000; total, \$435,000.

BIDS OPENED.

MARQUETTE, MICH.—The following bids for heating and ventilating apparatus for the State Prison were received by E. P. Rogers, President Board of Commissioners, August 24: Kruse & Barker, Milwaukee, Wis., \$11,790; Kelly & Jones Co., Pittsburg, Pa., \$12,907; Detroit Metal and Heating Works, Detroit, Mich., \$12,000; Samuel I. Pope & Co., Chicago, Ill., \$10,970.

BLOCK ISLAND, R. I.—The following bids for opening a channel between Great Salt Pond and the ocean were received by Joseph P. Cotton, C. E., of Newport, August 27: Hartford Dredging Co., Hartford, Conn., \$16,060; Frank Pidgeon Dredging Co., New York City, \$9,600; Charles H. Edwards, Boston, Mass., \$9,294; John Van Patten, Albany, N. Y., \$9,250; S. V. R. Hendrix, Easthampton, Mass., \$8,450.

MARQUETTE, MICH.—At a meeting of the Upper Peninsula Prison Board, August 26, the following contracts were let: Cell block, \$24,400; boiler stock, \$3,000; conduit, \$1,200, to Wahlmann & Grip, of Ishpeming. The water system was let to R. R. French, of Marquette, for \$7,100. Steam-heating and ventilation were let to Samuel I. Pope & Co., of Chicago, for \$10,970.

PHILADELPHIA.—Bids were opened by the Director of Public Works, August 20, for the continuation of the Manayunk Intersecting Sewer along Canal Street, 2,315 feet N. W. from Levering Street. The first section consisted of a brick sewer 2'10"x3'7", and the second of cast-iron pipe 2'9"x3'6". Bids for flushing-chamber, some 12-inch terra-cotta pipe were also received. The bids were as follows: R. A. Malone & Sons, at \$13.87 per linear foot for the brick sewer, \$25 per linear foot for the iron pipe, \$2,500 for the flushing-chamber, and \$2.56 per linear foot for the terra-cotta pipe; James Deehan bid \$13 for the brick, and \$13.08 for the iron sections, \$5,000 for the flushing-chamber, and \$3 per foot for the terra-cotta pipe; James Sullivan bid \$13 for the brick and \$15.80 for the iron, \$2,500 for the flushing-chamber, and \$3 per foot for the terra-cotta pipe; James F. Kennedy bid \$13.23 for brick and \$14.20 for iron sections, \$2,200 for flushing-chamber and \$3.50 per foot for pipe. The total cost of the section will be about \$32,000.

There were also bids opened for the construction of thirty-five small branch sewers, the principal one being two sections of a sewer on Girard Avenue. For the first section, 322 feet, 2,800 feet long, from Sixth to Broad Streets, John M. Mack bid \$4 per foot; P. C. & T. McEntee, \$3.25; B. F. Shelmire, \$3.87; James Deehan, \$3.50; H. P. McTague, \$3.29; John Noonan, \$3.09.

For the second section, from Sixth eastward to Frankford Road, a distance of 3,000 feet, the bidders were: John M. Mack, \$4; P. C. & T. McEntee, \$3.72; Shelmire, \$3.73; Deehan, \$3.50, and McTague, \$2.83 per linear foot.

MILWAUKEE.—Bids opened August 26 for repairing pier, North Point Pumping Station: William T. Casgrain will receive \$14 per pile, \$14 per M for 12x12 timbers, \$50 per M for white oak timber, 5½c. per lb. for screws, \$12 a cord for stone, \$15 per 1,000 feet for re-laying old work, 5c. per lb. for straightening old rods and bolts.

Bids opened August 26 for Section No. 5, Menominee Special Intersecting Sewer: J. J. Crilly, \$6,200; J. C. F. Brand, \$6,100; John O'Neil, \$5,937; William Forrester, \$6,200; James Markey, \$6,050. The contract was let to John O'Neil. The job will be very difficult, as a tunnel must be made under the river through marshy land. The work must be completed in six weeks.

BROOKLYN.—Bids were opened by the Department of City Works August 30, for building a station-house and court-house, as follows:

George W. Williams, for work complete, \$73,375; J. R. Schoonover, for work complete, \$68,700; Leahy & Moran, for work complete, \$62,000; P. J. Carlin, for work complete, \$62,000; W. & T. Lamb, Jr., for work complete, \$61,535; Charles Collins, for work complete, \$59,480; H. O'Rourke (bid informal).

AITKIN, MINN.—Bids were opened on construction of court-house as follows: T. P. Hardy, \$14,850; Gregg & Griswold, \$13,670; W. F. Chadbourne, \$13,475; Alexander Grant, \$13,200. Grant was awarded contract.

ST. PAUL.—The contract for wood-work on the new court-house has been awarded to the Bohn Manufacturing Co., of this city, \$78,000.

MILWAUKEE.—Stone curbing on Cedar Street from Ninth to Fifteenth Street: H. Vogt, at 55c. per linear foot. C. A. Beck & Co. were awarded the contract for furnishing 2,000 yards of cedar block for repaving streets in Fifteenth Ward at 55c. per square yard.

For paving Third Street with stone from Chestnut to Vliet Street: J. M. Cannon, \$2.84 per square yard; J. Clauser, curbing same street, 54c. per linear foot; stone curbing on Jackson Street from Ogden to Pleasant Street, 54½c. per foot, Fred Andres, Contractor.

PHILADELPHIA.—Bids were opened August 25 by the Survey Committee of Councils for the construction of thirty-five branch sewers. The following bids were also received for the construction of the Manayunk intercepting sewer from Levering Street northward a distance of 2,315 feet: R. A. Malone & Sons, \$34,603.80; James Deehan, \$35,168.50; James Sullivan, \$32,605, and James F. Kennedy, \$32,000.20. The contracts will be awarded after Director Wagner shall have examined the proposals.

JERSEY CITY, N. J.—Bids for furnishing a steam-boiler to the asylum were opened August 23 as follows: Hugh Leslie, \$1,375, will give \$15 per ton for the old boiler; John McLaren, \$1,720, and \$700 for the old boiler.

NEW YORK CITY.—The contract for repairs and alterations in the retreat building on Blackwell's Island has been awarded to James Moore at \$25,700.

CANAL WORK.—Superintendent of Public Works Shanahan has received these bids for rebuilding locks on the Black River Canal in this State: Lock eight, Thomas H. Stryker, of Rome, \$12,168; James E. Flood, of Sandy Hill, \$12,532. Awarded to Stryker. No. 48, Thomas H. Stryker, \$11,508; James E. Flood, \$9,805; Philip McGuire, of Forestport, \$12,760. Awarded to Flood.

MILWAUKEE.—The Schlitz Brewing Company have awarded the contract for furnishing the iron columns for their new malt-house for \$17,500 to William Bayley & Co.

J. C. F. Brand will lay 304 feet of pipe-sewer in Sycamore Street for \$547.20; Dan O'Driscoll, 702 feet, Kinnickinnic Avenue, \$1,368.34; John O'Neill, pipe sewer, Second Street, \$2.35 per linear foot; A. C. Murphy, 383 feet of pipe sewer in Garfield Avenue, \$564.19; J. J. Crilly, laying 431 feet of pipe-sewer in Fourteenth Avenue.

BOSTON.—The Boston Water Board received on Wednesday proposals for building iron roofs at the Chestnut Hill pumping station. The G. W. & F. Smith Iron Company bid \$8,675, and the Philadelphia Bridge Works, \$6,750. The contract was awarded to the Philadelphia Bridge Works.

BOSTON, MASS.—The following bids were received by City Engineer of Boston, Mass., for building ferries for the East Boston Ferries: McInnis & Parker (awarded), \$12,995; William A. Norton, \$11,000; J. N. Hayes & Co., \$14,250; William A. Kenrick & Son, \$14,670.

THE SANITARY ENGINEER AND CONSTRUCTION RECORD.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1887, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 16.
NUMBER 15.

PUBLISHED EVERY SATURDAY.

NATIONAL APPROPRIATIONS FOR RESERVOIRS IN COLORADO.

MR. ORANGE JUDD, for many years identified with agricultural journalism, has been visiting Colorado and is reported in the *Denver Republican* to strongly advocate the construction by the United States Government of reservoirs in the mountains of that State for the storage of water to be utilized in irrigating large tracts of land now unavailable for cultivation because of the absence of the water needed for irrigation. Mr. Judd says:

"There is no other way in which the general Government can accomplish so much good for the country as to expend a considerable portion of its surplus millions in investigations and then in establishing a system of reservoirs to conserve the vast quantities of water which run to waste every year and which, if husbanded and let down when needed, would add untold millions to the wealth of the country. At the head-waters of the great 'agricultural rivers'—the Colorado, the Rio Grande, the Arkansas, the two great branches of the Platte, and numerous other streams—a system of dams or embankments could be constructed across the gulches at comparatively small expense which would hold water enough to supply the wants of many millions of acres that would become veritable gardens and fields of the highest productive fertility. By a little co-operation among the citizens of this State, and perhaps of adjacent States and Territories, in the employment of one or more competent men to enlighten the members of Congress, they could be readily induced to make all needful preparations for preliminary investigations, and then for carrying out the idea to practical results. One hundred, or even fifty millions of dollars thus expended, would undoubtedly add thousands of millions of dollars to the productive resources of the country."

If there are no waterways within the State of Colorado on which Government money can be properly spent, it is not strange that the citizens of that State should claim a share of the money annually expended for internal improvements for the building of storage reservoirs to hold water for irrigating tracts of land now valueless, thus adding wealth to that community, just as in other localities it has been added by the improvement of water highways.

The point, however, on which this question must be decided in order to secure United States aid is, "Will the water thus stored be available for use by the citizens of more than one State, and will its disposition be under United States control?" If not, and if only available for one State, we should consider it a waste of time to try and secure aid from the United States Government.

NEW YORK INSANE ASYLUM ABUSES.

THE report of the Commission of the State Board of Charities of New York in the matter of the investigation of the New York Asylum for the Insane seems to be a carefully prepared and sensible document. The Commission find that the buildings have been greatly overcrowded, there being nearly two thousand patients, with proper provision for the care of only one thousand; that there has been undue economy of expenditure for food, and insufficient salaries paid to secure proper nursing and attendance; and that the cooking is bad, "made necessarily so by the inadequate appliances in a kitchen intended for five hundred patients and made to pass through its processes, called cookery, food for over 1,700 patients besides

attendants." As the commission remark, "this condition of things is wrong and shameful; especially does it appear so in view of the fact that the patients compelled to eat the mixtures set before them are not ordinary paupers, but insane persons—that is to say, sick persons, and many of them acute cases, requiring for their recovery, as well as comfort, wholesome, digestible, and nutritious food."

The responsibility for this state of things rests mainly on the Board of Estimate and Apportionment, who have refused to grant the sums necessary to secure proper treatment for the unfortunate wretches whose diseases and necessities have forced them into this asylum. The Commissioners of Charities and Correction are held, in a measure, responsible, because of their neglect to present each year proper estimates, with evidence of their necessity.

The whole system is a bad one, because of the unbalanced estimates, divided responsibility, and want of proper accountability.

The methods of relief recommended by the commission are divided into provisional and permanent, the former including the means which can be applied at once and which will certainly effect great improvement, the latter including changes in the system which will probably require State and possibly national legislation.

The Board of Charities and Correction clearly has a greater field of duty than it can possibly supervise personally, and it does not employ skilled and properly-paid agents to do that part of its work which it cannot do by its own members. The standard of efficiency, which seems to have been the sole thing kept in view, has been cheapness—cheap food, cheap cooking, cheap nurses—and the results are disgraceful to the city of New York, which is abundantly able to take care of its sick and insane poor without starving them or committing them to the charge of drunken, ignorant attendants.

NAVIGATION OF THE GREEN AND BARREN RIVERS IN KENTUCKY.

FROM a report to the Chief of Engineers by a board appointed for the purpose, consisting of Majors W. R. King, Amos Stickney, and A. Mackenzie, all of the U. S. Engineers, we learn as follows: The questions especially given them to answer were: What are the commercial importance and value of the works and property of the Green and Barren River Navigation Company? They were also to furnish estimates of the cost of making commerce free by the purchase of the rights and franchises of the company.

These rivers lie wholly within the State of Kentucky, and drain about 10,000 square miles. Their general direction is north-west, and the Green, after receiving the waters of the Barren River, empties into the Ohio about eight miles above Evansville, Ind.

About fifty years ago the State undertook to improve the river by locks and dams. Four locks and dams on the Green and one upon the Barren were completed, and by means of them a continuous navigation for vessels of four-foot draught was obtained to Bowling Green, 175 miles from the Ohio.

The scheme was operated by the State until 1868, when the Navigation Company was chartered and the control transferred to it for thirty years, making it practically owner of the locks and dams.

HOUSE IN CAMDEN, N. J.

WILSON EYRE, ARCHITECT.

Green River has some remarkable characteristics. Rising in the central part of the State, it flows with a gradual descent nearly south-west to within 100 miles of its mouth, and then north-west to the Ohio. The country drained is comparatively level, and the river is free from sudden freshets.

For the last 150 miles of its course it has the remarkable depth of twenty to thirty feet, with only occasional obstructions by rocky reefs. This great depth is the probable cause of its freedom from ice, making the lower end a noted harbor for boats from the Ohio in the ice season. Another peculiarity of the river is the considerable number of tributaries which are navigable for fifteen to thirty miles of their course. Seven such are named and there are others. The width varies from 300 to 600 feet and the banks are bold, with an abundance of timber and stone for the building of dams, etc.

The structures that have been built were well done, the locks being 150x36 feet, which is, however, too small for present requirements. The State attempted to repeal the act of transfer to the company, but the Supreme Court decided such action illegal. It at the same time said that the State could, under the demand of public necessity, resume control by paying a just compensation. The State in 1886 ceded the dams and locks to the United States on condition that it extinguish "the claim of the company to exact tolls and control the river."

The evidence taken goes to show that these streams are the natural outlet of a country rich in mineral and agricultural wealth, but that they are virtually closed to competition by the prohibitory tolls exacted by the Navigation Company. The value of existing commerce is given at \$6,000,000 per year.

The money value of benefits to accrue by a release from these tolls is estimated at \$30,000 per year and the intrinsic value of the works at \$350,000.

The Board, therefore, reaches the following conclusion :

The Board is of the opinion that, in justice to the country tributary to the Green and Barren Rivers, the present obstructive tax on its commerce should be removed, and it is also of the opinion that the commercial importance of these rivers is sufficiently great to justify the general Government in extending aid to their improvement.

There appears to be three methods by which the general Government can secure control of the Green and Barren Rivers and their works of improvement :

(1) By purchasing the chartered rights on the most reasonable terms the Green and Barren Rivers Navigation Company will accept, as provided for by the act of the Kentucky Legislature.

(2) By condemnation, with just compensation, as determined by the proper legal tribunal. This method is also contemplated by the act of the Kentucky Legislature, which cedes the works to the United States on condition that the claims of the company are extinguished by purchase or otherwise.

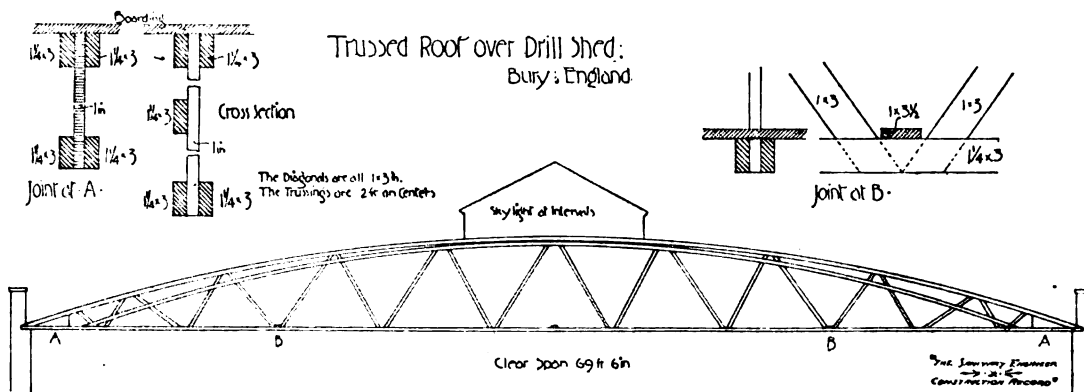

(3) By accepting the works and assuming control of the improvements of the Green and Barren Rivers, on the condition that the State of Kentucky will first extinguish the franchise, as suggested by the State Court of Appeals. On such a basis, the Board is of the opinion that the interests involved are sufficient to justify the general Government in reimbursing the State in an amount not exceeding \$350,000, the estimated present intrinsic value of the works.

PURIFICATION OF WATER BY AERATION.

THE Hoboken, N. J., Water-Works, where the process of purification practiced has been that of pumping air into it under high pressure, recently found that the water in the reservoir was troubled with the growth of algæ during the warm weather of this summer in spite of the aeration of the water in the force-main. The experiment of aerating the whole body of water in the reservoir is now being tried, under advice of Professor Leeds, who is understood to have suggested the aeration in the main, which has proved ineffectual in the late excessive heat. Perforated pipes have been laid in the bottom of the reservoir, and air pumped through them, "converting the whole reservoir into a boiling spring," as is stated in some of the reports. This has, in its turn, been effective in purifying the water. The cost is not given.

MAYOR HEWITT has reappointed Mr. James S. Coleman Street Cleaning Commissioner for another term of six years, writing a well-deserved and complimentary letter in which, after recognizing the difficulties the Commissioner has had to contend with in keeping the streets of New York clean, by reason of the occupancy of many of them by trucks and vehicles of all sorts, and the constant eruption of others by the steam, gas and electric-light companies, which makes it impossible to secure pavements that can be cleaned, the Mayor says :

"I believe that you are more anxious to render efficient service and make a good reputation than you are to get the salary which the law awards to you. I have, therefore, concluded that you are the fittest man to hold the position which you occupy, and I therefore announce to you that after the most careful deliberation and patient examination, I think you have earned the reappointment which I gladly make as due to your devotion to the public service."

NEWARK BAY IMPROVEMENTS.

LIEUTENANT GEORGE MC. DERBY, Corps of Engineers, has submitted his annual report upon the river and harbor improvements under his charge in New Jersey. A survey of Newark Bay disclosed the existence of another shoal about one mile below the one surveyed in 1884, about 800 feet long and having a least depth of 8.06 feet in the channel. It is not deemed advisable to extend the dyke beyond the length already constructed until positive evidence is obtained that the dredged channel across the shoal will not maintain itself alone. It is suggested that \$100,000 can be profitably expended during the next fiscal year.

BRITISH CORRESPONDENCE.

I NOTICE that in a few of the steam-cranes used for hoisting material, etc., for new buildings in London, that wire rope is being used in place of chains. There is, of course, less friction and the travel is easier.

During a very severe fall of rain consequent upon a thunder storm the main sewer crossing the Metropolitan Railway at Baker Street Station burst, and the line was flooded over the metals to the height of the platform, completely putting a stop to the traffic. The rainfall itself was also sufficiently heavy to stop the traffic at Farringdon Street Station on the same line after 8 o'clock. This is the second occasion within the past two years that such a mishap has occurred, the previous occasion having been at the Sloane Square Station.

An insurance company is in existence in Frankfort-on-the-Main, organized for the purpose of guaranteeing insurance against damage consequent upon burst water-pipes or defective water-fittings. The rate of insurance is about 9 1/2 d. (19 cents) per £100 insured, and the company is, apparently, well patronized. It is estimated that accidents consequent upon this cause of leakage or overflow are about a hundred times as frequent as accidents by fire.

OUR DETAIL SHEET.

OUR illustration this week shows details from a house at Dorchester, Mass., built about the year 1800.

BUILDING CONSTRUCTION DETAILS.

No. VI.

(Continued from page 68.)

IT sometimes happens that a piece of construction may be carried out by rule-of-thumb, or even without any rule whatever, in such a manner as at first glance to seem ut-

terly impracticable, and still be perfectly secure and trust worthy as far as it goes. An example in hand is the trussed roof, if such it may be termed, over the cavalry drill shed at Bury, England, a diagram of which is reproduced herewith. The space to be covered by the roof is 69 feet 6 inches by 106 feet. It seems almost impossible that for such a span a roof could be constructed with no timber in it heavier than 1 x 3 inches. But that is actually what has been done. The entire roof is made with 3-inch strips nailed together to form trussed rafters of the shape shown by the drawing. The top and bottom chords are doubled, the oblique pieces are but one inch thick, and the inner bowed chord is simply nailed on one side of the obliques. The feet of the chords where they meet are joined by a web of sheathing boards. These trussed rafters are spaced two feet on centres, and besides being firmly braced laterally by the roof-boarding which is nailed directly to them, they are further stiffened against yielding sidewise

by being connected at three points by 1 x 3 1/2-inch strips nailed across the bottom chords. The roof is constructed entirely of pine, and has an ordinary tarred composition covering, with light wooden skylights at intervals.

Perhaps it is hardly fair to speak of this roof as having been laid out by rule-of-thumb. The lines are just such as are often adopted for heavy bridge-trusses, and indeed a better form could hardly be devised for producing a light, stiff truss, with no waste of space or material. The total rise is but six feet, and the trussed rafters are so light that four men would easily be able to lift them into place without the aid of a derrick, as each rafter contains only 136 feet of lumber and would weigh less than 300 pounds. And it is quite possible that the rafters were scientifically calculated and the pieces carefully reduced to an exact minimum, though in the absence of certain information to the contrary one would more naturally infer that the roof was built by a clever mechanic who had plenty of 1 x 3-inch stock on hand and at a venture used it in imitation of some well-known truss.

The margin of strength in such a trussed beam is of course quite small. The weight of a single rafter is 300 pounds. The weight of the roof-boarding over a single bay would be also about 300 pounds, and allowing an equal weight for roofing composition and a section of a skylight, the total dead load on a single rafter would be 900 pounds. For purposes of rough calculation, apply the formula which Trautwine gives for trusses, on page 270 of his hand-book :

$$W = \frac{8 A d C}{l}$$

when W = total distributed breaking load in pounds, A = area of bottom chord, d = depth in inches, l = clear span in inches, and C = the ultimate tensile strength of the material per square inch, in this case 10,000 pounds. Substituting the values we have

$$W = \frac{8 \times 3 \frac{3}{4} \times 72 \times 10,000}{12 \times 70} = 25,714 \text{ pounds.}$$

With a factor of safety of three, this allows 59 pounds per foot for snow, wind, and other extraneous pressure. In reality not less than six would be admissible for the factor of safety in such a case as this, but as a matter of fact, the roof would seem to be strong enough for all it ever has to bear, for, in the place where it is built, neither snow nor wind would ever be sufficient in quantity or violence to cause any disturbance, though such a construction would not outlive a single winter in our climate.

This cannot be called good construction, being entirely too flimsy in its nature to stand for any length of time unless carefully watched. The strength, or rather the holding together of the rafters, depends chiefly upon the nailings, and, as we believe, there is but a single nail to each end of a diagonal, the chances of failure are quite large. But, at the same time, the roof is so daring and so light in its construction one cannot but feel interested in it; and, under similar conditions, a roof might be constructed which would require but little more material and be thoroughly substantial in every respect.

This roof was standing in good order in 1870, when it was measured by Mr. C. F. Weeks, architect, Boston, to whom we are indebted for the data from which the drawings were made. We are unable to say whether it still remains intact, but should not be greatly surprised to know that a broken nail or an unusually violent storm had caused its ruin.

RECENT SEWER CONSTRUCTION.

No. IX.

(Continued from page 378.)

CHISWICK SEWAGE-WORKS.

[Prepared for THE SANITARY ENGINEER AND CONSTRUCTION RECORD by Joseph Hetherington, Resident Engineer.]

THE bearing of the agitator is designed to exclude grit, and is shown at Fig. 16. Notwithstanding the rapid movement, the lime and solids in the sewage rapidly forms a deposit on the machine to a thickness of three inches and more. On placing some of this in a warm atmosphere it melts and runs to slush like snow. The agitators and mixers are driven by a small vertical engine in the engine-house. The lime-mixers revolve about ten times per minute. Their peculiar

FIG. 16. BEARINGS OF SEWAGE AGITATORS

shape and construction were to some extent due to other fixtures of which they were made part. These were for mixing the lime and sulphate of alumina by hand and have been abandoned. By them the two chemicals were mixed together and an intermittent supply sent down pipes to the bottoms of the engine-wells. Dr. Tidy being called in condemned that system, and the newer agitators and mixers were put in by Mr. Strachan to give effect to Dr. Tidy's advice. He also advised that between the addition of the lime and the addition of the alumina, an interval should be given, and in accordance with this, Mr. Strachan put in the winding channel, giving the sewage a run of 300 feet, at the end of which the alumina is added. The alumina is in the form of slabs, perfectly soluble, and it is added in solution, prepared by filling a tub with a perforated bottom with slabs, and spraying a jet of water over them. The solution drains out at the perforations and is distributed over the stream, which then receives another stirring by a precisely similar machine to that used for stirring in the lime. The second agitator is situated in the mixing-house, through which the winding channel passes. (See general plan Figs. 2 and 17.) The quantities of chemicals used will be referred to presently.

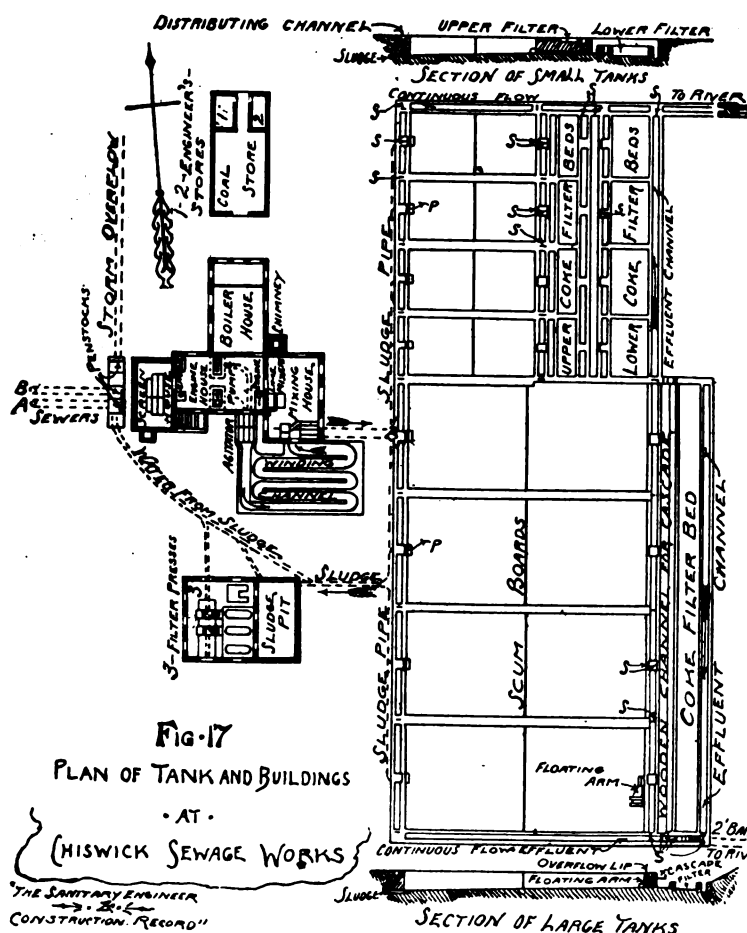

FIG. 17

PLAN OF TANK AND BUILDINGS

• AT •

CHISWICK SEWAGE WORKS

The sewage, after passing through the alumina agitators, is conveyed by an underground pipe to the distributing channel of the tanks, entering at the point A, Fig. 17. The channel extends the whole length of the eight tanks, and a wooden sluice-door to each tank admits sewage to any one of them. The channel is also fitted with sluices

at right angles placed between the tanks, and with sluices at its ends opening to channels along the outsides of the end tanks. By aid of these, and similar doors in the channel at the right-hand ends of the tanks, a continuous flow through either set of tanks can be worked. (Some of the sluice-doors are marked S in Fig. 17.) This sewage can be sent into the first large tank at A, back through the second, back again through the third, and brought back again through the fourth to the channel at the left, whence by opening the end sluice it can be sent along the channel at the side of the fourth, and thence to the river if it is high water. If the tide is out it can be turned along the wooden channel and allowed to fall in a cascade into a trench below and out to the river via the coke filter-bed. The small tanks can be worked in a similar way, and also in a great variety of other ways, as they are provided with an intricate set of channels, sluices, and filter-beds. There are eight sluices to each of the small tanks, and four to each of the large ones. The four small tanks are admirable for experimental purposes, but in practical working the whole intricate set of channels and filters is ignored. The continuous flow system is also only used on the very rare occasions when the tide is too high to allow of the use of the low-level filters concurrently with a prolonged rainstorm. This contingency has only occurred once in the past five years, when all the tanks were full and the tide was up. The ordinary method is to fill a tank at a time, shut it off, and go on filling another. Each full tank is allowed about two hours' complete rest, and the effluent is then drawn off by a floating arm, passed through the lower filter-beds, and out to the river. The filter-beds themselves have also fallen into disuse since the revolving screen was put in. The filters to the small tanks can each be used separately, but the large tanks have one long bed only. The side walls of the filter are perforated at the bottom, and by this plan only a layer of coke on the bottom of the bed came into contact with the sewage. When in use they were filled about two feet deep with coke, which, after remaining some three months, was removed and used as fuel for pumping. The smoke from the chimney-stack had a disagreeable odor in consequence, and this contributed to the disuse of the filters. A plank 9x4-inches is extended across each of the tanks, and is floated in grooves at the sides as the tank fills. The object of this is the prevention of scum getting to the floating arms. The floors of the tanks slope to the left, and a pocket is made at p, in which the sludge-valve is fixed. The sludge is swept down towards this, and passes into a pipe which delivers it into the sludge-pit. A tank is cleaned every day. The walls between the tanks are three feet thick, made of a brick casing nine inches thick, and the space filled with concrete. The floors of the large tanks are of concrete, of the small ones brick paving; and the filter-beds throughout are paved with bricks. The effluent, by continuous flow, can be discharged at 18.6 above O. D., the highest tide on record being 17.6 O. D. The walls on the south sides and east ends of the tanks, where there is least sunshine, have a tendency to grow green, and much scrubbing is necessary to keep them clean. The following are the leading dimensions of the tanks:

Large Tanks.—Length, 94' 6"; width, 40' 4"; depth 6' 0" to 7' 0" = 24,755 cubic feet = 154,844 gallons each.

Small Tanks.—Length, 50' 0"; width, 23' 6"; depth, 6' 0" to 7' 0" = 7,637 cubic feet = 47,734 gallons each.

Total tank capacity, 810,312 gallons; total tank area, .46 acre.

The sluice doors for the channels are made of wood; the frames are of oak, with angle-irons in the grooves to carry the cross-bar, also of iron. In this bar is mounted a gun-metal nut operated by a hand-wheel, which lifts and lowers the door by a screw. The frame is built flush in the brick-work of the channels.

Figures 18 and 19 illustrate the floating arms in the small tanks. They are made of galvanized iron one-sixteenth of an inch thick, and raised by drums of the same material. The drums are much too large, and are all half-filled with water. The lower end of the arms pivots into an iron valve-box, which is fitted for a 9-inch pipe, through which the effluent is passed below the upper filter-

FIG. 18

beds. The operation of this detail will be readily understood from the figures. The arms in the large tanks, Figs. 20 and 21, are on the same principle, but differ in construction. They are made to draw the water off much closer to the sludge, a depression being made in the tank-floor for this purpose. The floats are two rectangular boxes, pivoted at the top lip of the arm. These floats are made of galvanized iron, and have a 15-inch outlet-pipe. Fig. 21 illustrates a difference between the large and small tanks, in the former having an overflow-lip made by lowering the wall at one side of the trench by six inches. When used in continuous flow working, the water wells over the lip and drops into the channel behind. A sluice-door is provided also, and the flow can be sent that way instead of over the lip. The sludge-valves are at the left-hand ends of the tanks, Fig. 17, and are the same valves as for the floating arms, and are worked from the top. The tank-floors fall a foot in their length, and in the large tanks six inches towards the centre as well. When a tank is to be cleared of sludge the walls are first scrubbed all round; the water left by the floating arm on

FIG. 20

the top of the sludge is then run back to the sewer by the same pipe that takes the sludge, a shunt being provided in the pipe to deflect its flow either to the sewer or the sludge-pit. Finally the sludge is pushed down by manual labor towards the valve, and delivered into a pit ready for pressing.

Like many other precipitation-works, Chiswick works had the sludge difficulty. It was at first deposited in earth-pits, there to dry by evaporation and percolation. The latter process was soon stopped by the glutinous

sludge making the ground water-tight, and evaporation being very slow, the available space began to get short. The odor from the beds was powerful and roused the neighborhood, resulting in a Chancery suit. Practically all the sludge made between 1879 and 1884 was on the ground, and even without the goad of a Chancery suit the board would have soon had to face the question of some fresh way of sludge disposal. They had indeed met at the works and decided upon the adoption of filter-presses months before the Chancery proceedings, but the delay in waiting first for the Local Government Board to hold an inquiry and then the further delay of their sanction to borrowing the money, brought the summer round again. Notice of proceedings was served on a Saturday, and the board had the work of putting up pressing apparatus commenced with on the next Monday morning. Under such circumstances there was no time to mature plans or gain any useful knowledge of pressing arrangements elsewhere, and orders were simply given to an experienced contractor in this class of work to put up presses with all speed, according to any plan he thought would best suit the circumstances at Chiswick. The outcome of this was far from satisfactory, as will appear from the description of the plant.

The sludge from the precipitation tanks flows by gravity to the sludge-pit beneath the pressing shed (see Figs. 22 and 23). As previously stated, the top water from the sludge comes down the same pipe, and an opening is made in the pipe near its entrance to the pit. The man in charge can here see when the water begins to bring sludge, and by means of a shunt can turn the stream into the pit. After standing in the pit for a short time a subsidence takes place, some water coming to the top. This is drawn off by an arm operated by hand. It is lowered into the top water, and having drawn the liquid off is raised again. The sludge is raised by a suction-pipe connected with the two pressing vessels and with the sludge-pit. The valve to either vessel being open, an air-pump is set to work to exhaust the vessel and pipe, the sludge being thus drawn up. As it is entering a quantity of milk of lime from the lime-mixer above is syphoned over into the pipe, and the two enter the vessel together. The vessel being full, the suction-valve is closed, and the valve to the press opened. Compressed air, which has been stored in an air-vessel of similar shape and size to the pressing vessel, is turned into

der, but by making it double-acting a better distribution of work is secured. See Fig. 22, where S is the steam-cylinder, p the air-pump, and c the air-compressor. The pipes are shown in the same figure. The lime-mixer is a wrought-iron cylinder with a perforated bottom on which the lime rests. Beneath this is a conical part, into the bottom (apex) of which compressed air is admitted. The lime is thrown in and water turned on till about seven cubic feet has run in. When the lime is slaked, and just previous to filling a vessel with sludge, the air is turned on at the bottom of the mixer, causing a fierce ebullition of the contents of the vessel. The inlet of the syphon which draws off the contents is beneath the perforated bottom of the cylinder, so that stones and cinders do not pass. The pressing-vessel and press are further illustrated in Fig. 24. A shaft carrying four arms of 1-inch round iron traverses the vessel, and is kept revolving by

hind the block is filled. A clothes-peg happening to go in with the first rush will tear half-a-dozen cloths in its passage. Sludge escapes at the rents, gets behind the cloth, and blocks up the corrugations in the plate, and the press works slowly from want of drainage. In any case, the corrugations clog in time with the finer particles which escape through the cloths with the first rush of water. This ceases when a layer of solids has formed in the cloth. The plates are cleaned at the time the cloths are changed. At first cloths of jute supplied by the makers of the presses were used. These were estimated to last three months, but in practice they were always found completely rotten in three weeks. With jute, too, it cost £4 10s. to clothe a press, as each cloth cost 3s. 9d. Flax cloths were then tried, made up on the works at a cost of 2s. 4d. each. These always last one month, without a tenth of the trouble and patching the jute re-

FIG. 24 SECTION OF MONTEJUS' AND FILTER-PRESS

the engine. It does not prevent an accumulation of sludge forming along the bottom, as shown by the dark shading. Between the dams of heavy solids are spaces which remain filled with water. The vessels have a capacity of 100 cubic feet each, equal to $5\frac{1}{2}$ times that of the presses, this being the proportion wet sludge bears to cake, but owing to their horizontal position all the contents can never be expelled, as will be seen by a reference to the figure. On the average each vessel has to be filled three times to make two presses full of cake—often twice filled to make one press full. The shafts wind on to themselves rags, hair, etc., and further diminish the contents of the vessels. They require cleaning out frequently, and a man has to get in every time to get the shaft clean. A small mudhole is put in the bottom of each vessel to wash out at. The loss of time and of energy in the form of air blown to waste is simply enormous. It is seldom that a vessel can have a charge of sludge drawn into it in ten minutes; often it takes fifteen. Not less than four hours every day is wasted in this way, while the engine is running all the while and the men's pay going on. The average working hours of the men are between fifteen and sixteen per day. Instead of two men two-thirds of their working time, as was estimated, it takes two-thirds of their existence. The consumption of coal is very heavy. It is not easy to get at, as

quired. The Chiswick presses have twenty-four circular plates; these give less filtration area than square plates of the same width, but square plates are apt to squirt unless some other means than a central screw is used for closing the press. The screw as used at Chiswick is rather a barbarous method, for the friction on the end is immense, and the straining of the men in closing the presses is painful to witness.

The water expressed from the sludge is taken back to the sewer and pumped up with the sewage. Much of the sludge is taken away by market gardeners for manure, but no payment is made for it. If allowed to accumulate in a heap it heats and gives off a most offensive odor, but this may easily be prevented by covering up the heap with earth.

It is a little singular that filter-presses were not generally adapted long ago at works where the sludge difficulty had to be faced. Their usefulness was proved some thirty years ago at Leicester by Mr. Wicksteed. In a patent specification, dated 1856, a filter-press is described, "which may be applied to express water from sewage matter, whereby a cheap and valuable manure is formed." The number of patents taken out for filter-presses since that time is extraordinary. Like other machines, ninety-nine out of every one hundred patents concerning them are useless. There is one that might well be put in practice—viz., to close the press by hydraulic pressure instead of screws. Hydraulic power might also be applied to force in the sludge.

The description of the works is now completed, but before giving diagrams of flow, etc., a few words may be permitted on the necessity of competent supervision of the machinery during its manufacture and erection. Chiswick plant illustrates this very well. Take the pumping-engines for example, on the efficiency and constant readiness of which the immunity of the town from sewage-flooding depends. The design of these engines is exceedingly ingenious and compact, but the details have been carried out in a slovenly manner—with very expensive results to the ratepayers. The cylinder covers are fastened on by $\frac{3}{4}$ -inch bolts in 1-inch holes. When a cover has to be removed the bolts are run round in the holes, and, in order to get at their heads, the wood-lagging has to be removed. Thus an operation requiring only minutes occupies hours. Competent supervision would have insisted on a better arrangement. Down the pump-well numerous instances of a worse kind occur. A piece has been drilled out of every pump-barrel immediately over the lower valve to form a mudhole. This may have been necessary, but some compensation should have been made for the metal removed in so dangerous a place—dangerous because the valve has a conical seat and acts like a wedge in the barrel. Already one has split from this cause and has had to be removed. The pumps rested on the brick floors of the

FIG. 22 GENERAL ARRANGEMENT OF SLUDGE PRESSES

the charged vessel and the sludge driven into the press. The charge having been expelled and the press filled with cake the press-valve is closed and the charge of compressed air which now occupies the place of the wet sludge in the vessel is blown out to atmospheric pressure, the air-pump is set to work, and the operation repeated. When the press is opened the cakes drop into a truck underneath the presses to be removed outside. Compressed air is supplied by a horizontal air-compressor, supplying one-third of a cubic foot of air at atmospheric pressure at every stroke. The air-pump is worked by the same engine. In this air-pump the piston is made to act both on its in and out stroke. The cylinder of the air-pump has a port in the middle of its length, and each end is a valve. When the piston passes the port, the air enclosed is expelled by the valve at the end. A further portion of air expands into the cylinder, and when the piston passes the port on its return stroke the enclosed air is again swept out at the other end. The result is the same as if the piston were single-acting and the air admitted at one end of the cylin-

der, but by making it double-acting a better distribution of work is secured. The steam is supplied from the pumping-engine boilers, but it is not less than $4\frac{1}{2}$ tons per week. This is $3\frac{1}{2}$ times what it ought to be with a well arranged plant worked by compressed air, perhaps the most extravagant that can be devised. Every time a vessel full of compressed air at 120 pounds is blown off, about $3\frac{1}{2}$ millions of foot-pounds are absolutely wasted. The chambers of the presses are 36 inches diameter, and each press contains about 18 cubic feet, the charge of cake in one press weighing about 10 cwt. About 8 pounds of lime is used to each hundredweight of cake. Gray-stone lime is used for this purpose, the Clay Cross lime used in treating the sewage being far inferior for the purpose. Without lime it is impossible to press a firm cake. Clay Cross and chalk limes make the cakes like soft-soap, and much scraping is required to get them off the cloths. With gray lime cakes drop out of the press like boards. Where the sewage is badly screened, masses of rags and such like matters get impacted in the hole through the plates, and only the part of the press be-

wells, and were held down by girders, which were built over lugs on the barrel. (See Fig. 25.) This arrangement was strong to hold the barrel down, but weak to hold it up when the bricks were pulverized at the bottom of the well. Consequently, several lugs broke off, and the downward motion of the pumps being arrested by the delivery pipes, one of these snapped off at the throat, needing another new barrel. The carrying arrangement

FIG. 26

FIG. 25

shown in Fig. 26 has now been adopted, and the floors of the wells cut out and oak planks six inches thick laid in, over which again iron plates one-quarter inch thick and three feet square have been placed for each pump to rest on. The new lugs permit the barrels to be drawn out without cutting the girders out of the walls. The exhaust-pipes were made with lead joints, which worked leaky from the jarring and rocking of the condenser, also carried on the same girders as the pumps. The strains set up in the condensers by the breaking off of the lugs on the main pumps broke both engines' condensers. These have been replaced by larger ones which admit the exhaust-pipe by a gland, allowing expansion and contraction of the pipe without pulling the joints apart, as was the case with the old condensers. The delivery pipes were connected by lead joints, always leaky from the movement of the pumps. Flanged pipes have been substituted for these. The injection-pipes to the condensers were made with lead joints in such positions that calking was impossible and leakage (air-drawing) incessant. They have had to be replaced by screwed pipes. The rams were made in design as shown in Fig. 27. Several had their ends pulled out by the heavy

OLD RAMS

NEW RAMS

valves they have to carry, and new ones made as in Fig. 28 are substituted. The rams are always full of putrid sewage which leaks in through the hole for the valve spindle. Other defects might be mentioned, but enough has been said to show how essential a competent inspector of machinery is in such work, where so much depends on its good working order. The engine in the pressing-shed affords another illustration which should be laid to heart by local authorities. This machine was repeatedly denounced by the resident engineer in the course of its construction, but owing to the great need of its work being commenced as early as possible to comply with the Chancery order, the only thing that could be done was to require a guarantee for six months from the makers. They gaily offered to guarantee it for twenty years, but after working six weeks only, it was admitted by these gentlemen themselves to be in such a bad state that it would be cheaper to them to put in an entirely new engine, rather than attempt to fulfill their guarantee of the old one. This they accordingly did, stopping the work a whole week to put in the new one. Without a competent person to point out the defects in this machine, the original guarantee of three months would have been shuffled through in all probability, and the board would have possessed a machine at once a source of danger in Chancery and a curse to those who had charge of its working. These things should be a lesson to other boards who lean too much on the civil

engineer whose design for the works they have accepted. Clerks of works are provided for brick-work, and there is equal need for a similar functionary in machinery. Such a one would have saved Chiswick great risks as well as some hundreds of pounds.

Since 1883 the flow of sewage has been recorded daily, as also the rainfall and the height of the tides (both of which affect the flow); and from February, 1885, daily records have been kept of the sludge turned out of the filter-presses. In the spring of the present year the height of the water in the subsoil has been daily observed, but the observations are not sufficiently extensive to warrant any deductions. Movements occur in the ground-water level, and the leakage appears greatest when the water is highest—and that is all that can be said now.

Sheets are kept in the engine-room in which are set down the height of the sewage in the pump-well, and the time of starting and stopping the pumps. The sewage is not pumped below one foot over the inverts; when that level

is reached the pumps are stopped, and they stand till the water rises to about four feet. These particulars are graphically set out in diagram form every week, as shown in Fig. 29, where two days are taken from actual records—the first a dry one and the second a wet one, with a rainfall of .98 inch. The time the engines are at work is shown by black lines underneath, and the flow put down in figures below. It will be observed that on the second day the sewage rose with great rapidity against one engine, and even against both engines together. There was, however, a heavy subsoil leakage going on at the same time. There is a storm-overflow for a case of this kind, it is true, but so long as the pumps can hold the sewage below eleven feet it is not to be used. It can only be used when the tide is down in any case. Storm-overflows have furnished occasion for much sus-

picion on the part of certain persons who know of their existence. Dark hints are thrown out about their surreptitious use in the night, either by authority to save expenses, or by the workmen to save themselves the trouble of pumping and treating. For the past five years and a half, at any rate, Chiswick overflow has not been used. It is kept locked and no one can open it without the knowledge of the engineer.

To return to the record of the flow—the weekly diagrams are combined into a yearly one, where the curve is determined by the number of gallons pumped each day. The rainfall and tides are entered in this one also, as shown in Fig. 30. In this diagram, the flow is divided into two parts, the dry-weather flow (sewage proper) and rain, and leakage. The first part is shaded in Fig. 30 with full lines, the second with dotted lines. The flow is put down in figures, as also the rainfall and heights of the tides in the spaces under each section.

The sewage proper is ascertained by striking an average of the summer flow when leakage is at a minimum. In 1883, this average worked out to 28.3 gallons per head per day. The population has increased from 17,000 at that time to 20,000 in 1886, but the sewage flow per head does not increase in the same proportion, because one large factor is constant—namely, the sewage from two large breweries. The sewage flow is now estimated at 25 gallons per head, equal to 500,000 a day of sewage proper. In 1886 the total flow never fell below this figure on any days except Sundays, when the flow falls off by about 90,000 gallons on the average. The excess over 500,000 after excluding that due to rain may be put down to leakage, which is never absent at Chiswick.

The quantity of water due to an inch of rain is in round numbers 1,000,000 gallons. Its amount is ascertained by taking the average flow of a number of consecutive dry days, and noting the increase which occurs on the wet day. Favorable opportunities for this occur several times in each year. Thus in March, 1885, the average flow for 14 consecutive dry days was 625,450 gallons. This dry period was broken by a fall of .48 inch of rain on the fifteenth day, the flow being increased to 1,173,120 gallons. Deducting the average of the preceding 14 dry days, leaves 547,670 gallons due to .48 inch, equal to 1,140,973 gallons for one inch. By a like process, a fall of 1.37 inches in June gave an increase over the then dry-weather average of 1,268,970 gallons, equal to 926,255 gallons for one inch. From a number of similar instances, the resulting average is in round numbers, 1,000,000 gallons for an inch of rain at the present time. In 1883, this quantity of rain gave an

FIG. 29. FORM OF WEEKLY DIAGRAM OF SEWAGE FLOW AND WORK OF PUMPS

FIG. 30. FORM OF YEARLY DIAGRAM SHOWING SEWAGE FLOW, RAINFALL AND TIDES.

increase of 645,000 gallons, which has risen to 1,000,000 by the additional houses erected since that time, and by some road-water being admitted. In Fig. 30, the months of February and August, 1883, are illustrated, as they show in a marked manner the excessive leakage in the Chiswick sewers. The dry-weather flow is taken at 482,126 gallons, and to this is added an amount for rain in the proportion of 645,000 gallons for an inch. All above the resulting line is leakage. It will be noted that the August flow is frequently below the average dry-weather flow of that year, and also that the tidal curve influences the sewage curve above. These diagrams are over five feet long and one foot high, and they show, when colored, the fluctuations in sewage flow in a very graphic manner.

Whence comes the enormous leakage? A part is directly due to the tide, which gets into the sewers in some un-

known way whenever the tide rises above 14 feet O. D. The leakage is heaviest when the average height of the tides is highest, and then also the subsoil water is highest, since the latter responds readily to the tides. Thus in the two months shown in the figure the average height of the tide in the first was 13 feet 2 inches, and in the second 17 feet 5 inches above O. D. In the second month may be seen the effect of the tide about the 7th and 21st, when the springs occur. The same thing is observable throughout the year, and if the tides run high or there is a heavy flood in the river for several days the leakage rapidly increases.

When the leakage is as great as in the February illustrated, the sewage is as clear as drinking-water in the early morning. During some of the heaviest days the flow was 135 gallons per head of population. It will be understood from what precedes that the annual flow is very variable. In 1883 the total flow for the year was 253½ millions of gallons; in 1884, 208½ millions; in 1885, 256½ millions; and in 1886, 280½ millions.

The treatment consists of the application of lime and sulphate of alumina. The lime is a chalk lime from Clay Cross in Yorkshire. Before being put into the mixers to form the milk-of-lime, it is thoroughly slaked into the form of a damp powder. The quantity used per gallon averages about seven grains of the unslaked lime per gallon of sewage. The judgment of the workmen regulates the amount according to the strength of the sewage, more per gallon being used in the day-time than in the night.

Clay Cross lime gives the best effluent of any lime used at Chiswick. Ordinary chalk lime is very good, but contains a large proportion of large flints; gray-stone lime gives a poor result.

The sulphate of alumina is used in the proportion of five grains per gallon of sewage, on the average, the judgment of the men being relied on to regulate it to the ever-changing foulness of the sewage. It is delivered at the works in the form of slabs about 18 inches long, 9 inches wide, and 4 inches thick. The following is an analysis of it:

Alumina.....	14.00
Peroxide of iron.....	.75
Sulphuric acid in combination with above bases.....	33.81
Free acid.....	.00
Water.....	51.44
	100.00

It is guaranteed to contain 46.68 per cent. of sulphate of alumina. It has hitherto proved far superior to any of the numerous substitutes experimented with at Chiswick.

The quantity of sludge at Chiswick could only be guessed at previous to the erection of the filter-presses. The best authorities gave as results to be relied on from 120 to 140 pounds of pressed sludge per head per annum from a population similar to Chiswick. The working of the presses at Chiswick shows that these figures are far from reliable. The amount of pressed sludge is recorded every day, and may be shown in tabular form, thus:

	Tons per million actual flow.	Tons per million sewage proper.	Amount per head per annum in pounds.	Total for year in tons.
1885	8	12	245.2	2,190
1886	7.728	11.967	244.5	2,184

The cost of pressing a ton of sludge at Chiswick is abnormally high, owing to the malarrangement of the machinery. It has hitherto been about 5s. per ton of cake. The details now are:

Wages.....	£200
Lime.....	140
Cloths.....	60
Coal, gas, oil, etc.....	100
Total of pressing per annum.....	£500

The cost of chemicals for treating the sewage is about £1 10s. per million gallons. The total annual working expenses since the commencement of the works is as follows:

1879-80.....	£168
1880-81.....	808
1881-2.....	1,020
1882-3.....	1,613
1883-4.....	1,281
1884-5.....	1,500
1885-6.....	2,038
1886-7.....	2,053

A change of management occurred at the end of 1882 and at the end of 1884. The cost of the year 1884-5 includes five months' sludge-pressing. The last two years' expenses include sludge-pressing for the whole year.

The cost of the whole scheme was about £100,000, of which £26,500 has been expended on the purchase of the land and the erection of the buildings and machinery at the outfall-works.

FIG. 31. DIAGRAM SHOWING DEATH RATE FOR 33 YEARS

The profit of sewage-works is not to be reckoned by the interest table, but rather by the death-rate; and, when looked at in this way, Chiswick can show a good many people now alive who would have been dead but for the drainage-works. This point can best be shown graphically by reproducing a diagram due to Mr. Strachan, which shows the death-rate for the past thirty-three years. This is illustrated in Fig. 31, with which this description may fitly close.

THE DOMESTIC ENGINEERING IN THE ARMY MESS-HALL AT DAVID'S ISLAND, NEW YORK HARBOR.

THE accompanying plan, elevation, and sections of the (new) United States Army mess-hall and kitchen at David's Island, New York Harbor, gives a very good idea of the building and its appointments, as lately constructed by Captain George H. Cook, Assistant Quartermaster, U.S.A., for the accommodation of 1,000 enlisted men.

The dining-room is 50x152 feet in plan by 16 feet high, floor of Georgia pine, the walls being 18 inches thick, of brick, with air-space, and hard plaster-finished on the solid walls, and wainscoted in white wood and white pine.

The kitchen building is 104 feet long by 30 feet wide, with a boiler-house at one end, the kitchen proper being 30x58 feet.

COOKING APPARATUS.

The cooking apparatus consists of thirteen steam-roasting ovens for meats, etc.; six cast-iron vegetable-steamers; four steam stock-boilers; one coffee, one tea, and one hot-water urn, the positions of which can be seen in the plans.

The steam-roasting ovens are of the class known as "Ashcroft's." They are each 33 inches long by 26½ inches wide over all, with double sides and bottoms, between which the steam circulates; a pressure of forty pounds giving sufficient heat for the cooking or roasting of meats.

The vegetable-boilers or steamers are each of 33 gallons capacity, with galvanized-iron baskets to hold the vegetables, and the stock-boilers are made of copper, with brass annular heaters, and each is of 80 gallons capacity, and all with copper covers. The urns are termed self-feeding Maracaibo, and are made of copper. The water-urn is 36 inches in diameter, and holds 100 gallons, and the tea and coffee urns each hold 80 gallons. They have water-gauges on the sides to show the height of their contents.

At the opposite side of the kitchen are the sinks and strainers for wa-hing dishes, etc., their position not being shown. Car-tracks from the tables in the centre of the kitchen run to a turn-table at the centre of the dining-room, and thence run down the centre aisles in both directions. The food is distributed by these cars and the dishes collected again and returned to the sinks in the kitchen.

The floor of the kitchen is granolithic and it is inclined in the direction of cast-iron drains in the floor at positions parallel to the line of cooking utensils and sinks.

No pipes are passed through the floor, and all steam return or water-pipes for the cooking apparatus are either overhead or run on or near the back wall below the kettles,

entering from the boiler-room, which is much lower than the kitchen at the corner, and, running both ways, facilitating this arrangement, as no pipes pass doors or passages.

STEAM-BOILERS, ETC.

Two horizontal multi-tubular boilers, each 10 feet long by 36 inches diameter, with thirty 3-inch tubes, supply steam for all purposes.

They are made of "Otis" best boiler-steel throughout, the shells being No. 2 American wire gauge in thickness (¾ of an inch) and the heads ⅞ of an inch.

The boilers are made with three taper-courses, the laps being backward from the fire.

The grates used are the McClave shaking grate of 7½ square feet to each boiler. In addition to the regular common safety-valve each boiler is supplied with a 2-inch nickel seat and disk Consolidated Co.'s lock safety-valve, set to blow at fifty pounds.

The dining-room is warmed by twelve wall coils, nine pipes high, of 1-inch pipe, and the store-room, cook's rooms, and bath-room are warmed with compound coil-radiators, cased, with registers in the top. The kitchen has one radiator inside the door to the yard and also a long coil of six 1-inch pipes at the back of the sinks and drain-boards to keep traps, etc., from being frozen in cold weather should the cooking apparatus be long enough out of use to let the kitchen cool. The size of the main pipes and return-pipes are shown on the plans, with their positions and the positions of their valves. The main steam-pipe is indicated by a double line, while the return-pipe is dotted. The main pipes are near the ceilings and the return-pipes are in a space between the floors and the ground of about four feet. The return-pipes and all pipes within the boiler-room are covered with Teop's asbestos and felt covering and canvas; the mains in the dining-room being uncovered.

The water of condensation is returned by gravity from the heating apparatus, and also from the cooking apparatus, but in the latter case a Kieley pump-governor and Worthington pump is introduced into the circuit in case the returns from the cooking kettles require pumping when much water has to be heated.

FIG. 2.

Figure 2 shows the principle involved in the return-pipe of the cooking apparatus for passing the water into the boilers by means of the pump and governor, in case it does not properly return by gravity when large quantities of cold water are suddenly let into the cooking-kettles, etc.

CISTERN AND HOUSE-TANK.

The position of the three cisterns, which are each twelve feet in diameter by ten feet high, is shown, and the course taken by the roof-waters in entering them. A pump in the boiler-room takes suction from either or all of these cisterns and forces the water into an iron tank at the highest part of the boiler-house. The water then flows by gravity to the kitchen and other parts of the building for all purposes.

A grease-trap is built in the yard into which the waters from the cooking apparatus all pass, and all other waste-waters from the kitchen pass into the same trap or interceptor for the purpose of cooling it. From this trap a rustless-iron drain is run to the water of Long Island Sound.

A study of the drawings, which are very complete, will show other important details to any one particularly interested in the construction of similar buildings, and there is no doubt the proprietors and builders of our large summer hotels can study this plan to their advantage and prevent making sink-holes of filth of their back door-steps. We have personally inspected the premises and know whereof we speak.

The cooking apparatus was furnished by Messrs. Duparquet & Huot, of New York.

FRONT ELEVATION

HOT-WATER HEATING AND FITTING.

BY "THERMUS."

No. X.

(Continued from page 381.)

LET us now make Fig. 24. It is a fairly long diameter elbow, the radius being $1\frac{1}{2}$ diameters of the pipe, and into it we screw a pipe the same as that shown in Fig. 22. (Shown by the dotted lines at the edges.) Incidentally it is explained elsewhere in these articles that to double the radius of a bend is the means of

FIG. 24

lessening the head required for change of direction to about one-quarter what it would be for the shorter radius—in other words, the head required decreases somewhat faster than the inverse of the square of the radius—therefore, for change of direction in Fig. 24 we have, say, $\frac{3}{8} = 9\frac{1}{2}$ diameters, plus no diameter for entry, plus 5 diameters for friction, the elbow being longer, $14\frac{1}{2}$ diameters, to which if we add 8 diameters (as we did in Fig. 23, for the same reasons as there given), it will bring the value up to $22\frac{1}{2}$ diameters. If we go further and lengthen the elbow to 5 diameters radius, then C D will become nothing; E will be, say 8, as before, and F $7.8 = 14.8$.

FIG. 25.

If we make one more diagram (Fig. 25) with the elbow and pipe the same diameter throughout, the radius of the elbow being $1\frac{1}{2}$ diameters, then we have C D $= 9\frac{1}{2} + E = 0. + F = 5.0 =$ total, 14.8; and if this elbow is further drawn out, so as to equal 5 diameters radius, then we have C D $= 0. + E = 0. + F = 7.8$ total.

These are approximations that I have reason to believe are not far wrong, and though not absolutely correct my apology for publishing it lies in the fact that it gives the practical man or mechanic some definite idea of what the resistance of an elbow really amounts to, and how greatly it can be lessened and made almost nothing by proper radii of elbows and easy points of entry.

With a return bend, the loss for change of direction is just double what it would be for a 90-degree elbow. The loss for entry will be no greater, but the same for similar fittings and ends, while the loss for friction will be about doubled, as the bend is about twice as long as an elbow.

The shortest elbow or bend must have a radius of one-half its diameter, and if the back of it is round, the loss of head for such an elbow is about sixteen times as great as it would be in a bend of four diameters, and eight times as great as in one of one diameter, according to "Trautwine." So that the advantage to be obtained by length-

ening the radii of common fittings for hot-water work ever so little is obvious.

Therefore, if we consider the loss of a common elbow as equal to that caused by 100 diameters of a pipe, being 38 for change of direction, 58 for entry, and the remainder for friction, the resistance of a common close and return bend will be equal to about 76 diameters for change of direction; 58 for entry into a square-ended pipe, and say 8 for friction—142 diameters.

If the radius of the bend is doubled, the 76 for change of direction becomes about 19. If an easy entry is made the 58 drops very rapidly, say to 8 again, and friction is increased slightly on account of the increase of length, giving the value say of 40—a most decided gain.

In box-coils for hot-water work it is probable that return bends of greater radii than one diameter cannot be used, but by care their resistance value may be reduced to that of 50 diameters of the same pipe. So that in an inch box-coil four feet long the length of pipe and the bend can be made to have equal values, whereas, by neglect the resistance in the bend may be increased to three times as much.

(TO BE CONTINUED.)

Novelties.

Under this heading we propose to describe and illustrate appliances of probable interest to our several classes of readers. The selection will be made without reference to the wishes of agents or patentees, being governed solely by considerations of novelty, ingenuity, and probable interest to readers, and especially the fact that they have not been elsewhere described. As a rule we shall make no comments, and it is to be distinctly understood that a notice does not imply approval. No charge will be made for these notices, and any offer of pay for their insertion will insure their omission. We shall be glad to have our attention called to novelties suitable for this section.

MASON PRESSURE-REGULATOR.

We were not able to state who were the makers of the reducing-valve illustrated in our Novelty Column last week, page 381, invented by W. W. B. Mason. We are now informed that it is manufactured by the Mason Regulator Company, 22 Central Street, Boston, Mass.

VALVE-DISKS AND THE METHOD OF REMOVING AND RENEWING THEM.

THE accompanying sketches show late novel improvements in the Jenkins valve, or that class of valves employing a removable disk or valve-seat of vulcanite or of other comparatively soft materials.

Heretofore in valves of this character the packing has been made in the form of a disk, and has been secured to the valve-head, or in a recess in the valve-head, by a stud which passes through a hole in the disk and a nut which

screws upon the end of the stud and laps upon the outer surface of the disk.

In use the disk is subjected to pressure and to other influences which cause its side edges to adhere to the walls of the recess, and, consequently, upon the removal of the holding-nut the packing cannot readily be removed from its holding-recess. To overcome this difficulty the present arrangement is brought forth of connecting the disk or ring with the holding-nut, so that upon unscrewing it to remove it from the stud the ring or disk of packing is loosened or turned in its holding, so as to become disengaged and drop from its holding-cavity upon the removal of the holding-nut from the stud.

Several methods are shown in the sketches of accomplishing this, and their operation is obvious as affording means of removing the old or worn-out packing by its adhering to the nut or by its being split or pulled from its position sufficient to be removed with the fingers.

The inventor is Charles Jenkins, of Boston, Mass. The makers are Jenkins Bros., of 71 John Street, New York.

REGISTRATION OF PLUMBERS URGED.

THE British Medical Association, in convention assembled, has passed the following resolution: "That the section of Public Medicine, convinced of its absolute necessity in the interests of the common weal, is strongly of opinion that an organized and efficient system of registration of plumbers and of plumbing work should be put into force in all parts of the Kingdom." This is of course the old story put forward from a new quarter, but there does not seem to have been any provision made for assisting this organized and efficient system of registration which is so emphatically desirable in place of the desultory registration that is now being carried on.

TO PREVENT WATER IN A TANK FROM FREEZING.

A CORRESPONDENT in Boston suggests as a supplement to our reply to Mr. C. Fitzgerald, page 299, issue of August 13, a branch from the exhaust-pipe into a tank, as shown in accompanying sketch, with stop-cock that can

be kept open cold nights. He writes: "If the water-heater is good for anything no trouble will be found in heating the tank-water if the cock A is kept open." It would assist matters if the pipes were covered to prevent radiation.

SPECIFICATION FOR HEATING-APPARATUS, FORMULA No. 10.

PUBLISHED BY J. J. HOGAN, NEW YORK.

We have received from Mr. John Hogan his Formula No. 10, being blank forms of specifications for heating apparatus. These forms are intended to facilitate the preparation of specifications for heating. They are divided into different sections and are intended to save writing. Blank spaces are provided in each section in which the architect or engineer may make known his detail requirements.

Correspondence.

All correspondents should send us their names and addresses, not necessarily for publication, but as a guarantee of good faith and because it is often necessary to communicate with them for additional information before printing their communications. Anonymous letters will not be noticed.

SWITCH-VALVES WANTED.

NEW YORK, September 7, 1887.

SIR: Who manufactures switch-valves or mixing-dampers for indirect steam-heating? Would like to know sizes and prices.

S. H. & P.

A MAN TO PUT DOWN SCREW-PILES.

NEW YORK, September 9, 1887.

THE address of a good man for putting down iron screw-piles is wanted at this office.

SAN. ENG. & CON. RECORD.

EXAMPLES OF REVETMENT-WALLS AND OF LAND RECLAMATION WANTED.

NEW YORK, September 3, 1887.

SIR: Can you refer me to executed examples of revetment-walls of piles, earth, and stones, cost of same, and published description of methods and construction?

Also examples of land reclamation similar to Potomac Flats, technical description of such works, with cost of same.

W.

AMERICAN SOCIETY OF CIVIL ENGINEERS.

FIRST meeting this fall held September 7, Mr. C. C. Schneider in the chair. Written discussions on "Inspection and Maintenance of Bridges" were presented by W. S. Lincoln, Chief Engineer of the Wabash and St. Louis Railway, and by R. A. Shaler, engineer and contractor, Chicago, and read by the Secretary.

A letter was also read from Fred. C. Weir, a member from Cincinnati, describing 3 chord Howe truss bridges on the railway between St. Petersburg and Moscow, Russia. These bridges were planned in 1840, and work superintended by an American. The timber used in them was planed and burnetized. In 1861 they were inspected by Mr. Harris, an old Massachusetts bridge builder. "Mr. Harris examined every bridge with his little hatchet and reported that not a rotten timber was found."

Nine lithographic copies of the plans of these bridges were exhibited.

The following members were elected:

Calvin Harlow Allen, First Vice-President Buffalo, New York, and Philadelphia Railroad, New York City; Robert Bunker Coleman Bement, now engaged in planning and constructing water-works, St. Paul, Minn.; Peter Franklin Brendlinger, Engineer Pennsylvania Schuylkill Valley Railroad, Pottsville, Pa.; Alva Fisk Brown, General Manager Keystone Bridge Co., Pittsburgh, Pa.; George Devin, member of firm of Pittsburgh Bridge Co.; Roscoe Edwin Farnham, Assistant Chief Engineer of the Chicago and North-western Railway, Chicago, Ill.; Charles Hallett Graham, Assistant Engineer Department Public Parks, New York City; Charles Harlowe, Locating Engineer Chicago, Burlington, and Northern Railroad; David Christian Henny, Assistant to J. A. L. Waddell, M. Am. Soc. C.E., Cleveland, O.; Edward Willard Howe, Assistant Engineer, in charge of Park Construction, Boston, Mass.; William Dunbar Jenkins, Engineer in charge Randolph Bridge over Missouri River for Chicago, Milwaukee, and St. Paul Railway, Kansas City, Mo.; Horace Greeley Johnston, City Engineer of Salina and County Surveyor of Salina Co., Kan.; Alfred Potter Kirtland, Superintendent Western Penna. Div. Pennsylvania Railroad, Blairsville, Pa.; Frederick Nash Owen, Civil and Sanitary Engineer, New York City; Alfred Holden Simpson, engaged in directing work on behalf of the contractors upon the Dry Dock at Newport News, Va.; Otto Frederick Sonne, Principal Assistant Engineer Sibley Bridge, Orrick, Mo.; William Starling, Chief Engineer Mississippi Levee District, Greenville, Miss.; Alfred Thomas Tomlinson, in charge construction Red Hill Tunnel, Denver and Rio Grande Railroad, Badger, Col.; Francis Stuart Williamson, Engineer Wallis Iron-Works, Jersey City, N. J.

For Juniors.—Julius Baier, Assistant Engineer with Robert Moore, St. Louis, Mo.; Gilbert James Bell, Assistant Engineer Sibley Bridge, Orrick, Mo.; Frank Beresford, Principal Assistant Engineer Cincinnati, Hamilton, and Dayton Railroad, Cincinnati, O.; Edwin Mitchell, Assistant Engineer of Sewers, Norfolk, Va.; George Richards Sikes, with United States Construction Co., of Philadelphia, designing cable roads, Philadelphia, Pa.; George Oliver Tenney, in charge of Decatur Land, Improvement, and Furnace Co., Decatur, Ala.; Yoshichika Wada, in Engineer's Office, Sibley Bridge, Orrick, Mo.

THE following additional subscriptions to the new building fund of the society have been received since the last report given on page 183, July 16:

Subscriptions previously received.....	\$5,225	S. Rockwell.....	\$50

A special committee has been appointed, consisting of Messrs. T. C. Clarke, D. J. Whittemore, and J. M. Wilson, to solicit further subscriptions from members, and others who may feel interested in the society.

AMERICAN INSTITUTE OF ARCHITECTS.

OCTOBER 19 having been selected for the meeting of the American Institute of Architects at Chicago, the following local Committee on Arrangements, appointed by the Chicago Chapter, will co-operate with the Illinois State Association of Architects, and the request is officially made that all papers for the convention reach Secretary A. J. Bloor, Chicago, before October 1: Messrs. W. W. Clay, S. V. Shipman, F. M. Whitehouse, J. L. Silsbee, John Addison, Henry W. Hill and William Holabird.

TO CONFER WITH THE ARCHITECTS.

THE President of the National Association of Builders has appointed Mr. E. E. Scribner, President of the Contractors' and Builders' Board of Trade of St. Paul, the head of a committee to confer with the Western Association of Architects at Chicago, October 19, and formulate a plan for securing uniformity in contracts and specifications. Mr. Scribner's colleagues on the committee are Messrs. G. C. Prussing and P. B. Wright, of Chicago.

NEW YORK ARCHITECTURAL LEAGUE, THIRD ANNUAL EXHIBITION.

THE Architectural League announce that the exhibition which is to be held at the Fifth Avenue Art Galleries, 356 Fifth Avenue, beginning on Monday, December 19, will continue for three weeks. The coming exhibition is to have a different character from any preceding one. It is anticipated that the admission of decorated works, paintings, sculpture, will help to foster the popular interest, while at the same time representing fundamental objects of the league—viz., the promotion of architecture and the allied arts. Intending contributors are requested to send a description of the nature and approximate size of their exhibit as soon as possible. The wall-space of the gallery is 5,000 square feet, with 500 running feet of line. The floor-space is 5,300 square feet. The exhibition will consist of drawings not before publicly exhibited in New York, representing, as far as possible, the present condition of architecture and the allied arts.

The following are admissible: Architectural designs, perspective drawings, sketches in pencil, pen and ink, water colors, charcoal, etc.; elevations, working drawings and photographs of executed work; paintings in oil and water color of architectural subjects; sketches for interior decoration and furniture; designs and cartoons for stained glass; mural decoration; executed work, such as mosaics, stained glass, and decorative stuffs; wrought iron and metal work, sculpture, carving and casts, and models of architectural and decorative work.

The Executive Committee is Frederick Crowninshield, John DuFais, Bruce Price, Charles I. Berg, John Gelatly, John Beverly Robinson, William Convers Hazlett, Arthur B. Turnure, Edward H. Clark, John P. Riley, Frank A. Wright. Circular giving detailed information obtainable of Charles I. Berg, Secretary, 152 Third Avenue, New York.

THE Municipal Council of Paris has voted 321,260 francs to increase the security of the public in two of the municipal theatres—the Châtelet and the Gaîté. It is proposed to open and change doors of exit, to build interior staircases, supply iron curtains and fire-escapes.

WATER-WORKS STRUCK BY LIGHTNING.

DURING a thunder-storm on August 24 the water-tower of the water-works at Mount Vernon, N. Y., was struck by lightning and damaged, a hole being made in the side which allowed a considerable quantity of water to escape with great force. The supply was checked until the necessary repairs can be made.

MR. G. J. SPECHT, Civil Engineer, of San Francisco, writes, in the last quarterly number of the *Zeitung des Oesterreichischen Ingenieur und Architekten-Vereins*, an exhaustive article on the street cable railways of San Francisco, accompanied by numerous sketches and tables showing cost of maintenance, passengers carried, and relative cost as compared with horse railroads. The writer alludes to the cable roads of Chicago and Kansas City, but omits any mention of the Third Avenue Cable Road on One Hundred and Twenty-fifth Street and Manhattan Avenue in New York City.

A PRINTED statement from the Bureau of Statistics of the Treasury Department shows that during the seven months ending July 31 there were exported from Boston, New York, Philadelphia, and Baltimore, 35,984,667 gallons of crude mineral oil; 6,437,586 gallons of naphtha; 260,703,798 gallons of illuminating oil; 10,786,900 gallons of lubricating and paraffine oil, and 2,599,422 gallons of residuum. The total for this period was 316,512,373 gallons, against 329,515,224 gallons for the corresponding period of 1886.

PERSONAL.

MR. CHARLES E. EMERY has resigned his position of Manager and Engineer of the New York Steam Company. He proposes to devote himself to a consulting practice. He is now Consulting Engineer of the New York Steam Company, the Edison Electric-Light Company, the New York and Brooklyn Bridge, United States Revenue Marine, Pneumatic Dynamite Gun Company. His services can also be secured as an expert in certain classes of patent-cases.

COMMANDER GEORGE W. SUMNER, U. S. N., has been ordered to duty at the Naval War College. Lieutenant W. C. Cowles has been detached from duty as inspector of steel at Pittsburg, Pa., and ordered to ordnance duty at Washington Navy Yard. Assistant Engineer Emil Sheiss has been detached from the "Ranger," and ordered to duty in the Bureau of Steam Engineering. Commander Charles D. Sigsbee is detached as a member of the Examining and Retiring Boards, and ordered to duty at the Naval Academy.

THE survivors of the Engineer Brigade had a reunion at Canandaigua, N. Y., August 25. The following officers were elected for the ensuing year: President, John F. Davidson, of Elmira; Secretary, Major E. O. Beers, of Elmira; Treasurer, Sam B. Williams, of Rochester. A resolution was passed requesting Colonel Fowle to prosecute his preparation of a history of the engineers, and assuring him of the encouragement and support of the members of the association. Speeches were made by F. H. Hamlin, Captain John T. Davidson, of Elmira, Hon. John Raines, and the Hon. E. M. Morse.

ALEXANDER STUART, architect of Balmoral Castle and other buildings in Scotland, died recently at Peterhead. He was a brother of Mr. James Stuart, architect, of St. Louis, Mo.

MR. R. E. OSGOOD, now of the firm of Burkett & Osgood, architects, of San Diego, Cal., will continue the business alone.

ALVAN CLARK, one of the most celebrated makers of telescope-lenses in the world, died at Cambridge, Mass., August 19, aged eighty-three years. Mr. Clark, by profession a portrait painter, taking up the study of astronomy and the art of telescope-making as a pastime, developed his skill until his instruments made him known the world over.

ARCHITECTURAL COMPETITIONS.

MILWAUKEE.—The plans of H. C. Koch for a \$48,000 "full graded" school building have been adopted by the Building Committee.

TRADE CATALOGUE.

THE Gurney Hot-Water Heater Co., of 237 Franklin Square, Boston, Mass., have issued a pamphlet of instructions for erecting low-temperature hot-water apparatus.

MESSRS. THOMAS KELLY & BROS., of 75 Jackson Street, Chicago, Ill., have issued their 1887 catalogue and price list, illustrating the Kelly Self-Acting Water-Closet.

PROPOSALS.

TOO LATE FOR CLASSIFICATION.

PUMPING machinery for McKeesport, Pa. Until September 22. Capacity 5,000,000 gallons daily through 1,400 feet of force main, to a height of 305 feet. Endorse "Pumping-Engine," and address Joseph Ecoff, Superintendent of Water-Works.

WATER-PIPE.—The Water Commissioners, of Saratoga, N. Y., want proposals until September 4 for laying 4-inch iron water-pipe. Address Samuel F. Cobey, Clerk.

GRADING for two tracks, New York Division, P. R. R. Until September 15. Address W. H. Brown, Chief Engineer, 233 South Fourth Street, Philadelphia.

WATER-WORKS.—Proposals will be received until September 13 for pumping machinery, subiding reservoir, engine-house, and pipe-laying for the Holmesburg, Pa., Water-Works. Specifications may be obtained and drawings seen at Holmesburg. Address A. C. Shallcross, Secretary Holmesburg Water Company, Holmesburg, Pa.

BUILDING FOR DEAF MUTES.—Proposals for the new building of the Northern New York Institution for Deaf Mutes at Malone will be received up to September 20. Plans and specifications can be examined at the office of Hon. John I. Gilbert, President, Malone, after September 8, inst.

MILWAUKEE.—The Milwaukee Cement Co. have leased the Orton property on the Milwaukee River for \$2,000 per annum, and will add it to their already immense plant and will turn out 1,000,000 barrels of cement a year. The works will be doubled, and \$50,000 expended in new buildings, machinery and tramways. The Chicago, Milwaukee and St. Paul R. R. Co. and the Chicago and Northwestern R. R. Co. will extend their tracks to the plant and be completed for the spring trade.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

For works for which proposals are requested see also the "Proposal Column," pages 393-397-399-400.

WATER, SEWERAGE, ETC.

ACKRON, CAL.—will expend \$45,000 for water-works. Address the Town Board.

CENTREVILLE, IOWA.—Our correspondent writes: "No steps have been taken of for immediately putting in water-works. We are sinking an artesian well, with the ultimate intention of putting in water-works."

MORRISON, ILL.—Our correspondent writes: "We have and have had for the last five years as good water-works as any city four times our size in Illinois. None wanted."

ANOKA, MINN.—The Ram River lumbermen will build a dam at the foot of Mil's Lake. F. L. Pinney, of the Washburn Mill Co., will build it.

PAWNEE CITY, NEB.—On Monday the city will vote on introducing water-works. It is expected the proposition will be carried by a large majority.

HEKIMER, N. Y.—The election September 1 went strongly in favor of building water-works.

LOS ANGELES, CAL.—Incorporated is the Alessandro Land and Water Company; Charles French, J. E. Packard and others.

BAYFIELD, WIS.—Address Professor W. F. Dennison about water-works here.

HAYWARD, WIS.—will spend \$12,000 in putting in water-works.

SAN DIEGO, CAL.—Colonel George E. Waring, now in San Diego, estimates the cost of the new sewerage at about \$300,000. A proposal relating to this work will be found elsewhere.

CENTRAL CITY, NEB.—is agitating water-works. Contractors should put in propositions at once.

NORTH PLATTE, NEB.—is to have a new system of water-works, and a company formed for that purpose has filed articles of incorporation with the Secretary of State. The company's capital stock is \$125,000.

OID, MICH.—This city at its recent election voted in favor of water-works.

BURNET, TEX.—Our correspondent writes: "Our City Council on a petition, signed by very near all of the property holders of our city, have concluded to levy a tax for the purpose of sinking one or more artesian wells (which is our only chance for obtaining a supply of water) in the city, and, for that purpose, have appointed a committee to make contract with responsible parties for sinking said wells. The committee made a contract with one Mr. Taylor to sink and furnish a 6-inch well for \$2,500. Mr. T.'s partners not agreeing with him, he failed to execute bond for the thorough and faithful performance of contract, and the committee has been instructed to correspond with artesian well men and solicit propositions, etc."

TERRELL, TEX.—Our correspondent writes: "This city has already established a good system of water-works. We are now only increasing the supply of water by digging another large well."

NICKERSON, KAN.—Our correspondent writes: "Contract will be let as soon as bonds are sold for water-works. Bonds will be sold September 12, \$30,000, to run 30 years at 6 per cent. We will put in two 750,000-gallon pumps and about four miles of pipe."

EASTPORT, ME.—The selectmen have been authorized to enter into a contract with the Eastport Water Co., to supply the town with water from Boyden's Lake, the town to pay \$4,000 per year. The works shall be completed from Boyden's Lake on or before September 1, 1888.

MCKENZIE, TENN.—will obtain a supply of water from an artesian well.

PROVIDENCE, R. I.—City Council has received a report from Samuel M. Gray, City Engineer, on sewerage, and has ordered the preliminary work done at once.

SACRAMENTO, CAL.—Thomas Findlay, Superintendent of the California Water Company, is making arrangements to pipe water across the American River from the El Dorado County side to Newcastle, in Placer. It will take several miles of pipe and will furnish an immense volume of clear, pure mountain water. The citizens of Roseville are negotiating with Mr. Findlay to pipe the water to that place, where, in addition to its use for irrigation, it will be used for domestic purposes.

KEOKUK, IOWA.—The American Water-Works and Investment Company, of Pittsburg has bought a controlling interest in the Keokuk Water-Works.

CANNON FALLS, MINN.—The Cannon Falls Village Council has definitely decided to put in water-works on the top of Lime Kila Bluff, the water to be carried into the village by 1,500 feet of mains.

BISMARCK, DAK.—The water-works contractors have completed four miles of ditching and laid 7,000 feet of pipe, and built one reservoir.

CHEROKEE, IOWA.—Our correspondent writes: "The Council has not taken any action in regard to water-works."

DULUTH, MINN.—Address C. H. McMaster, Secretary of the Board of Trade, about the proposed sewerage system. It is proposed to introduce small pipe sewers.

MILWAUKEE.—Water-mains will be laid in Twenty-eighth Street, from Grand Avenue to Wells Street, in Twentieth Street from Wells to Cedar Streets, in Commerce Street, in Mound Street from South Bay Street to Lincoln Avenue, Harmony Street from Balfum Street 300 feet west of Buffum Street. Water-pipe will be laid in Muniego Avenue and North Canal Street, from Park Street to Clarendon, and fire hydrants put in as recommended by James Foley, Chief of Fire Department.

CHATTANOOGA, TENN.—We have already noticed that the city would vote on the question of bonding for sewers. Our correspondent writes, under date of September 2, that the proposition was carried by a heavy majority. The amount voted was \$50,000, and work will be begun as soon as arrangements can be made. A. C. Casey is City Engineer.

EAST WYOMOUTH, MASS.—Town meeting August 31 voted to raise water bonds for \$50,000 to be applied to increasing the water-supply.

SAVANNAH, GEO.—Well men should address at once the City Engineer, for the city will sink several new wells at the water-works.

ROCHESTER, MINN.—The Water Committee tested the new water-works September 1, and found them satisfactory.

KENT, O.—The Kent Water-Works have been accepted by the Water Committee.

ATLANTA, GEO.—The newly completed Clear Water Reservoir burst September 1, and involves a repair of \$9,000 to \$10,000.

ORLAND, CAL.—Address N. K. Specht about a great irrigation scheme here.

SENECA FALLS, N. Y.—The Water-Works Company has decided to build the necessary works to take water from Cayuga Lake.

BAR HARBOR, ME.—The Eden Water Company, Charles T. How, of Boston, President, will begin work at once on the water-supply for this place and neighboring points.

HUDSON, WIS.—will obtain a supply of water from wells.

WASHINGTON, PA.—See our Proposal Columns for water-works here.

CARLINVILLE, ILL.—Contractors have been here looking over sources of water, etc., with a view to putting in bids for constructing works. The city has already voted to have them. Address the City Engineer.

VALLEY FALLS, KAN.—The construction of water-works will be begun soon. Address the City Clerk.

LANCASTER, PA.—The Committee on Sewerage and Water-Supply are ready to receive bids under the plans of J. J. R. Croes, C. E., of New York City, for change in water-supply. Attend to this.

MANKATO, MINN.—It is reported bids for constructing the water-tank or reservoir will be readvertised, as those recently opened are too high.

PORTLAND, CONN.—proposes to build water-works soon. Address the Town Clerk.

SAN FRANCISCO, CAL.—Capitalists have formed a company to tap Lake Tahoe for power and irrigation.

MARINETTE, WIS.—The Marinette Council has adopted an ordinance giving exclusive franchise to the American Water-Works and Guarantee Company to construct water-works in that city.

COSHOCOTON, O.—will have water-works. Address the City Engineer.

MARION, IOWA.—Address the City Engineer in regard to the laying of additional water-mains at a cost of \$25,000.

BRIDGEPORT, CONN.—The Common Council has taken steps to ascertain the price at which the Bridgeport Hydraulic Company and the Citizens' Water Company will sell their works to the city.

AUGUSTA, GEO.—J. H. Shedd, C. E., of Providence, R. I., has been engaged by the Augusta Water Company to examine the reservoir and make plans and estimates for its completion.

TUCSON, ARIZ.—On September 12, C. M. Strauss, of the Board of Regents of the Territory of Arizona, will receive bids for sinking a well from 100 to 500 feet.

WAUWATOSA, WIS.—The water-works were tested and accepted Thursday, September 8.

DUBUQUE, IOWA.—City Council has extended the time for letting contracts for work on the sewerage system to September 15.

STROMSBURG, NEB.—An election has been called to vote on raising \$12,000 for water-works. Address the City Clerk.

SYRACUSE, N. Y.—A 24-inch main sewer will be advertised for in Gifford Street.

SAN DIEGO, CAL.—The Fallbrook Water and Power Company has been chartered, with a capital of \$300,000, to build dams, reservoirs, conduits, etc., to bring water from the San Margarita River. J. D. Hanbury and T. J. Wrampelmeier are directors.

SUFFOLK, VA.—Water-works are to be constructed. Address R. R. Prentiss.

FRAMINGHAM, MASS.—Our correspondent writes: "At the town meeting held the 6th of September, the town voted to dismiss the article in regard to the purchase of the water-works."

HEKIMER, N. Y.—We have previously noticed the election for water-works. Now our correspondent writes that the town will be ready to receive bids in two weeks.

RALEIGH, N. C.—J. L. Ludlow, of Winston, has the contract for building sewers here.

KENDALLVILLE, IND.—is asking for bids to construct water-works.

MILTON, CAN.—will construct water-works at a cost of \$20,000.

BRISTOL, TENN.—wants water-works. W. G. McDowell has made a proposition.

WINCHESTER, KY.—Mr. Garner will sink wells here for gas and water.

BOWLING GREEN, O.—Ferris & Holliday, of Jersey City, has submitted a proposition to build water-works here.

VANDALIA, ILL.—is receiving propositions for erecting water-works.

GALVESTON, TEX.—We have noted that extensive additions and improvements will be made in the water-supply. Commissioners are J. M. Brown, N. W. Coney, John Colter, Albert Weiss, W. F. Beer.

SPRAGUE, WASH. T.—Incorporated is the Sprague Water Company. Incorporators, George S. Brooke, D. K. McPherson, John J. Burns, and others.

WATER COMPANIES.—Incorporated are the Pasadena, Cal., Rincon Land and Water Co.; Ezra Dane, I. M. Hill, Edson Turner, George Bell, and George W. Dunmore, directors.

The San Felipe Land and Water Co., of Los Angeles, Cal.; Presley C. Baker, A. D. Childers, directors. The Montecito-Santa Barbara Water Co., of Santa Barbara, Cal.; W. S. Meach, Sacramento; E. H. Howard, San Francisco; J. M. Hunter and E. H. Peacock, Santa Barbara; and John W. Ellis, Los Angeles, directors.

The Nipomo Water Co., Nipomo, Cal.; I. B. Thayer, chairman; S. A. Dana, secretary, and P. Fry, treasurer; San Diego Water and Land Co.

POTTSTOWN, PA.—Our correspondent writes: "At this time the water company—a private corporation—does not intend to make any important changes in the water-works further than to lay more water-pipes (in streets not yet supplied, and in new streets laid out in our fast-growing town). In the near future, however, the basin must be enlarged or a new one made; the inlet-pipe must be taken out and one of greater capacity put in, or, which is most probable, the present source of supply and the basin discontinued, and a new one put in at a place two miles farther up the river. A new engine, pump, pipes, basins, etc., will be the result—equal to a new water-works, except the supply-pipes in the streets."

REDDING, CAL.—The Shasta Water Company, of Redding, has been incorporated; capital stock, \$300,000. Warren B. Ewer, San Francisco, and others incorporators.

RIVERSIDE, CAL.—J. S. Castleman, John Hall, and others have incorporated Hall's Addition Water Company; capital, \$40,000.

NORFOLK, NEB.—The recent city election authorizes the issuing of bonds to grade Main Street, put in a system of sewerage, erect a city hall, and purchase the necessary apparatus for a fire department.

HOLMESBURG, PA.—Proposals for water-works will be received until September 12. See our Proposal Columns.

SARATOGA, N. Y.—The Water Commissioners want bids for 4-inch water-pipe.

NORTH PLATTE, NEB.—A water company has been incorporated.

MILWAUKEE.—Second bids opened September 5 for repairing crib at pumping works: William A. Starke, \$2,024, and W. T. Costigan, \$1,975, are yet beyond appropriation available.

LANSINGBURG, N. Y.—Engineer Franklin is making estimate of cost and capacity of proposed new reservoir.

MANCHESTER, VA.—Address John S. Taylor about water-works to be built here.

FORT WORTH, TEX.—Incorporated is the Dallas City Water Company.

CARSON, IOWA, is asking for propositions to build water-works, costing \$100,000.

RIVERTON, NEB., has voted to issue bonds for funds to build water-works.

PHENIX, N. Y.—This town has voted by a large majority to have water-works.

SANFORD, N. Y.—A company is being formed to construct water-works. A pumping-plant will be wanted.

WALTHAM, MASS.—The Aldermen have advanced orders calling for \$19,000 of sewers.

HOLLIDAYSBURG, PA.—It is proposed to replace the wooden water-mains with cast-iron pipe.

St. JOSEPH, MO.—A sewer-system to cost \$45,000 to \$60,000, for Blacksnake Creek, will be built by the Diagonal Railroad Company. The City Engineer of St. Joseph has prepared the plans and specifications. Address him at once. Another sewer will be built by the Kansas City, St. Joseph, and Council Bluffs Railroad.

GAS AND ELECTRIC-LIGHTING.

RED WING, MINN.—The Globe Electric-Light and Power Company has been awarded the contract for lighting the town.

JAMESTOWN, DAK.—L. B. Durstine, of this city, has been awarded electric-light franchise.

The Shamokin Arc-Light Co., of Shamokin, has been incorporated; capital stock, \$10,000. A. Robertson, Pottsville; Holden Chester, C. C. Leader, George O. Moitz, and W. C. Smith, Shamokin, incorporators.

OWENSBORO, KY.—The Owensboro Mineral Company has recently begun boring for gas near the city limits. The well will be sunk twenty-five hundred feet, or until gas is reached. Colonel J. D. Powers, of this city, is President of the company.

COUNCIL BLUFFS, IOWA.—The Economic Light Company, recently organized to build gas works in the towns of the State, has begun work here. A plant will be erected and gas furnished at \$1.95 per 1,000 cubic feet.

MILLBURY, MASS.—The town hall will have electric-lights. The wiring is completed.

VICTORIA, TEX.—Address W. J. McNamara about constructing a plant for the refrigerating company.

PITTSBURG, PA.—The Kendrick Light and Heating Company has applied for a franchise. George B. Hill, F. Rohm, and others are interested.

The Duquesne Natural-Gas Company also wants a charter and franchise. W. H. DeWald, H. M. Bowman, and others.

CHATTANOOGA, TENN.—The Chattanooga Oil and Gas Company is sinking wells. Contracts for derricks let.

LAWRENCE, KAN.—Large additions are being made to the works of the Lawrence Gas Company under direction of E. L. Hopper, Gas Engineer, of Philadelphia.

MERIDEN, CONN.—The Meriden Gas Company and Meriden Electric-Light Company have consolidated with a capital of \$250,000, and George R. Curtis of the Gas Company was chosen President.

DUNDER, MICH.—A company with \$300,000 capital has been formed to bore for oil and gas.

FLUSHING, L. I.—The franchise for lighting the streets with electricity was sold September 6 to a representative of James H. Hurst, of New York. Steps will be taken at once to build the plant.

HALIFAX, N. S.—J. W. Chandler & Co. have nearly completed negotiations with the city by which the former will erect in ninety days an electric-lighting plant. It is said eleven firms are trying to secure the contract from Chandler & Co. to build and equip the station and plant.

AUGUSTA, GEO.—Two electric-light companies, one the Edison, the other the Thomson-Houston, are putting up wires to light the streets.

CENTRAL CITY, NEB.—Electric-light plant prospectors should address propositions to City Council, which is now considering the question of lighting the streets by electricity.

CHICAGO.—Incorporated is the People's Gas-Saving Association; F. S. Amick and others.

WELLSVILLE, O.—The Citizens' Electric Light and Power Company has been organized here with a capital stock of \$50,000.

PLATTSBURGH, NEB.—An electric-light plant is to be erected here.

KENNEBEC, ME.—The Kennebec Light and Heat Company has made arrangements to erect an electric-light plant.

SHEFFIELD, ALA., has let a contract for lighting the streets with electric-lights.

GRAHAM, N. C.—Address L. B. Holt with propositions for constructing an electric-light plant for a cotton mill.

SUMTER, S. C.—Address D. J. Winn, Sumter Cotton Mills, about an electric-light plant for the mills.

CARROLLTON, MO.—An electric-light plant is wanted here.

MOUNT PLEASANT, MICH.—A company has been formed here to sink gas-wells and develop gas-plants.

SIOUX CITY, IOWA.—Pierce Bros., of Hudson, Wis., offer to put in a \$30,000 electric-light plant if the city will grant a franchise, with permission to erect poles.

PASADENA, CAL., wants electric-lights for the streets.

JAMESTOWN, DAK.—The city has contracted with Lee B. Durstine to furnish electric-lamps for street-lighting. The Edison Company will furnish the plant.

ELIZABETH, N. J.—The Westinghouse Electric-Light and Power Company has petitioned City Council for a franchise to permit them to erect wires for street-lighting.

MARYSVILLE, O.—J. C. Guthrie, Village Clerk, is receiving bids for constructing gas-works here.

WESTCHESTER, PA.—Contract for lighting Westchester State Normal School was given to gas company at the bid \$187.50 less than the Edison Electric-Light Company, of Westchester.

ELECTRIC-LIGHT COMPANIES.—We notice the following: The Edison Electric-Light Co., of Salina, Cal., incorporated; William W. Roller, Robert M. Ridgway and others, incorporators.

The Sprague Electric-Light Co., of Sprague, Wash. T., incorporated; George S. Brooke, D. K. McPherson, John J. Burns, incorporators.

The Iron Mountain Electric-Light Co., of Iron Mountain, Mich., incorporated; Arthur D. Moore and others, incorporators.

SUMTER, S. C.—An electric-light plant will be established here.

TRENTON, N. J.—The contract for a police patrol system has been awarded to Pierce & Jones.

BATESVILLE, ARK.—The Davis Telephone Co. will erect seven miles of wire from here to Jamestown.

STEAM-HEATING, BUILDINGS, ETC.

ST. PAUL, MINN.—The Holland & Thompson Manufacturing Co., of St. Paul, have obtained a contract for heating-apparatus for the Spalding House, at \$18,000.

RALEIGH, N. C.—The time of opening bids for heating our public buildings has been extended to September 15.

MONTGOMERY, ALA.—At a meeting here September 5 the trustees of the A. and M. College at Auburn awarded the contract for building the laboratory to Floyd & Stephens, of Opelika, at \$11,000; Bruce & Morgan, of Atlanta, are the architects.

PEKIN, ILL., is organizing a steam-heating company.

SAN DIEGO, CAL.—The Elsinore Improvement Company is the name of a new land and town company incorporated to subdivide and lay out town sites and to do a general real estate business. F. H. Heald, G. C. S. Gilbert, H. L. Conard, S. M. Cambern, and Gilbert Dexter will act as directors for the first year.

MILWAUKEE, WIS.—The Board of Public Works wants heating-apparatus for schools. Write them at once.

MINNEAPOLIS.—Building Inspector Barnum has submitted his report for the quarter ending August 31, the following being a summary:

No.	Kind.	Valuation.
53	miscellaneous.....	\$396,532
16	brick stores.....	378,600
6	brick veneered stores.....	16,000
18	frame stores.....	25,560
17	brick dwellings.....	134,000
16	brick veneered dwellings.....	110,000
290	2-story frame dwellings.....	598,600
60	1½-story frame dwellings.....	36,675
40	1-story frame dwellings.....	8,884
784	additions and repairs.....	140,483
181	barns.....	44,385

The total number of permits issued during the three months was 1,481, and the estimated value of the different classes of structures, \$2,095,078.

ASHLAND, WIS.—A \$10,000 plant for the Lake Superior Soap Co. will be put in.

BRIDGES.

WACO, TEX.—It is reported that every bridge in Hill County has been washed away by freshets. A large outlay will be required to rebuild. Address the County Clerk of Hill County.

BUFFALO, N. Y.—State Superintendent Shanahan, of Albany, is advertising for bids for building a bridge over the Erie Canal at Hudson and Austin Streets.

VINTON, CAN.—James Morrison, of Ottawa, has the contract for building the masonry of a bridge over the Coulonge River, for the Pontiac and Pacific Junction Railroad.

CARLETON PLACE, CAN., has voted \$10,000 for an iron bridge over the river.

PITTSBURG, PA.—The Pittsburgh Dispatch states that the Pandanville Road will build a \$1,500,000 bridge over the Ohio River at Brunot's Island. Chief Engineer Becker is making plans.

CHATTANOOGA, TENN.—The Iron Bridge Company, of Decatur, Ala., has the contract for a bridge over the Tennessee River here, at about \$200,000.

KANSAS CITY, MO.—The Belt Line Railroad Company will build a bridge here. Address John Diebrick, Twenty-third Street and Broadway.

AMERICUS, GEO.—Address bids for building an iron draw bridge, 180 feet long, to B. H. Hardaway, Chief Engineer of the Americus, Preston, and Lumpkin Railroad, at Americus, Geo.

WILMINGTON, DEL.—Address C. E. Pugh, 233 South Fourth Street, Philadelphia, about a bridge which the Philadelphia, Wilmington and Baltimore Railroad Company will build.

SIDNEY, NEB.—It is proposed to build a \$45,000 bridge over the North Platte River.

IONIA, MICH.—Address J. J. McVean about a railroad bridge to be built for the Detroit, Lansing and Northern Railroad.

HINDOSTAN, IND.—The County Commissioners will build a \$40,000 bridge over White River.

MUSCATINE, IOWA.—The contract for stone-work on a bridge over Pappoose Creek has been given to Edwards & Walsh.

ELIZABETH, PA.—It is proposed to build a \$100,000 bridge over the Monongahela River.

SIBLEY, MO.—The Atchison, Topeka and Santa Fe Railroad will build a steel bridge here to cost \$1,250,000. Address J. F. Goddard, Topeka, Kan., General Manager.

FOND DU LAC, WIS.—Proposals for two iron bridges are wanted.

STREET WORK AND PAVING.

SAN ANTONIO, TEX., is negotiating \$150,000 of bonds to make local improvements.

OAKLAND, CAL.—Twenty-third Avenue will be improved with grading, curbing, and paving, and crosswalks; also Brush Street. Address A. C. Henry, Clerk of City Council.

BOSTON.—Notice of the following street-work is given: Widening Tremont Street, at Roxbury; opening of Calumet Street, at Roxbury; opening of Sachem Street, at Roxbury. Address the Board of Street Commissioners.

WHEELING, W. VA.—There is a movement here to raise funds to convert Camp Carlisle into a park. Address the editor of the *Intelligencer*.

ROCKVILLE, CONN.—A carriage road will be built around Snips Lake. Address G. W. West.

CHAMBERSBURG, N. J.—Change of grade of Wolverton and Clark Avenues, with other improvements, is advertised.

TRENTON, N. J.—Lamberton Street will be improved with change of grade.

FLUSHING, L. I.—Flagging for Washington Street sidewalks is ordered.

AUGUSTA, GEO.—Alderman Dempsey has a plan for building levees, 30 feet wide on top, all around the city.

WILKESBARRE, PA.—Paving is ordered on Chestnut and Hazle Street, and sewers and crossings in various streets. Address the City Engineer.

LAKEWOOD, ILL.—The engineer will advertise for bids for paving Diversey and Frederick Streets and Wright Avenue.

BOSTON.—Union, Dorchester, and Baxter Streets, South Boston, will be improved.

SYRACUSE, N. Y.—Contracts for street work have been awarded by the Board of Aldermen as follows: For furnishing 1,000 cords of hard limestone spalls at the crusher, to A. E. Alvord, at \$2.44; for delivering 100 tons of slag in each ward, to Frank Matty at these figures: First, Second, Fourth, Fifth, Sixth, and Eighth Ward at 50c.; Third at 38½c.; Seventh and Ninth at 60c.; Tenth at 3¼c.; Eleventh at 70c.; for paving the gutters of Harrison Street to Anthony McNamara at \$373.50.

JANESVILLE, WIS.—H. H. Macloon, J. R. Bleasdale, O. C. Ford, are a Council Committee on paving Milwaukee Street.

WEST STRATFORD, CONN.—Street-work and sewers (Grand Street) are advertised for. Address the Town Clerk.

PHILADELPHIA.—Plans for the widening of Chestnut Street have been prepared by the Bureau of Public Works.

GALEN AND SAVANNAH, N. Y.—A highway will be built from Savannah to Galen. Plans by Vandenberg & Saxton, of Clyde. Address bids to the Commissioners of Highways, until September 24, to the care of Vandenberg & Saxton.

RAILROADS, CANALS, ETC.

ST. CLOUD, MINN.—The general car shop and stock yards of the entire Manitoba Railroad system will be located here. About \$1,000,000 will be expended, work to begin at once. The St. Cloud Motor Line has been incorporated to build a street railway. H. C. Waite, John Cooper, and D. B. Searle are interested.

MILWAUKEE.—The Wolf & Davidson Steamship Company, of Milwaukee, was incorporated September 2. W. H. Wolf, T. Davidson, and F. L. Vance are the incorporators, with a capital stock of \$80,000. To build and operate steamboats and vessels is the object.

BILLINGS, DAK.—Dennis Ryan, of St. Paul, has been awarded the contract for building the Rocky Fork and Cook City Railroad, a new road.

MILWAUKEE.—The Milwaukee City Railway are to extend their tracks across the river.

MILWAUKEE.—The Milwaukee and Whitefish Bay Railroad Company will build a new road to run dummies.

ST. PAUL, MINN.—The St. Paul and Minneapolis Rapid Transit Co. has been incorporated for the construction of an elevated or surface railroad between the two cities, with a capital stock of \$2,000,000.

SIoux CITY, IOWA.—Address L. F. Wakefield, engineer, about the extension of the Sioux City and North-eastern Railroad.

NEW BRUNSWICK, N. J.—A company, composed of Christopher Meyer, Henry S. Little, Senator D. C. Chase, and Congressman John Kean, Jr., has been formed to build a new branch railroad twelve miles long between this city and South Amboy. The road is to cost \$100,000.

RAILROAD.—The North Dakota and Pacific Railroad Company has filed articles of incorporation with the Secretary of State, to build a railroad from some point in Norman County to some point in Dakota. The principal office is at St. Paul, Minn. The highest amount of indebtedness shall be \$15,000 for each completed mile of track. The incorporators are Charles G. Lawrence, Harris Richardson, and others, of St. Paul.

LARAMIE, WYO. TER.—A company has been organized here, with a capital of \$100,000, to build a street railway.

SPRINGFIELD, ILL.—Incorporated is the Cairo and Northwestern Railroad Company of Illinois. The principal office is to be located at Cairo and the capital stock is \$1,000,000. It is intended to construct the road from Cairo to East Cape Girardeau. The incorporators and first board of directors are Charles O. Patier, Fredolin Bros, Peter Neff, Edward A. Buder, and Henry Wells, all of Cairo.

LYNN, MASS.—The Lynn and Boston Railroad Company will lay new track on its grounds in this city.

SPRINGFIELD, ILL.—Incorporated are the Mississippi River and Ocean Navigation Company, at Alton, capital stock, \$5,000,000; to construct and operate ocean and river steamships; incorporators, Andrew H. Lucas, John F. Cahill, and William Lucas. The Underhill Mining Company, at Belleville, capital stock, \$2,000,000; to conduct a general mining business; incorporators, W. N. Homer, D. J. Canly, and F. M. Priester. The Rubicon Mining Company, at Belleville, capital stock, \$2,000,000; to carry on a general business of mining gold and silver; incorporators, G. A. Koerner, William Priester, and W. N. Homer.

STOCKTON, CAL.—A scheme is raised to cut a ship canal from Stockton to deep sea water. The earth removed will be used to improve adjoining lands. Address the City Engineer for further information.

ASHEVILLE, N. C.—The Asheville and Tennessee Railroad is incorporated to build from Asheville to the State line; President, S. R. Kepler; Vice-President, Matt Atkinson.

DENVER, COL.—A franchise has been granted to George W. Bowman and others, to build a cable railroad on Golden Avenue and other streets.

OAKLAND, CAL.—The Oakland, Alameda and Laundry Farm Railway Company filed articles of incorporation recently. The directors are, J. H. Woodward, F. J. Moffit, H. T. Smith, E. G. Matthews, and J. H. Costigan.

LORAIN, O.—The Lorain Street Railroad Company, of Lorain, has been organized with a capital stock of \$5,000.

CONYERS, GEO.—A street railroad will be built. Address F. M. Ridley, of the company.

PROVIDENCE, R. I.—The City Council has authorized the Mayor to appoint a committee of three engineers to consider improved facilities for railroad terminals.

MINNEAPOLIS.—The Minnesota and Northwestern Railway Company will build a round-house and machine shops in South-west Minneapolis to cost \$135,000.

SAVANNAH, GEO.—The construction company of the Atlanta and Hawkinsville had agreed to take the road to Barnesville in consideration of \$50,000 and the right of way, if the directors would approve. The directors refused to consent.

PORT TOWNSEND, WASH. T.—Articles of incorporation were received from California with several prominent railroad capitalists' signatures affixed August 26 for the purpose of incorporating, constructing and maintaining a railroad from Port Townsend to the Columbia River. The capital stock is \$3,000,000, in 30,000 shares.

LOS ANGELES, CAL.—Articles of incorporation were filed yesterday by the Sierra Madre Improvement Co. It proposes to construct and operate a street railway from the Santa Anita station on the California Southern Railroad, a distance of five miles. The directors are N. C. Carter, Emile Deutch, A. D. Hawks, (Secretary), A. D. Trussell, (Treasurer), and L. Richardson.

KNOXVILLE, TENN.—An English syndicate with a paid-up capital of \$1,000,000 will commence at once the erection of two blast-furnaces here, of 200 tons capacity each. A member of the syndicate states that 1,600 hands will be needed. Two new railroads will be let to contractors within thirty days, and the third within sixty. Two other roads are pointing this way, and officials say are sure to come.

The Sevier County Court has agreed to submit a proposition to a vote to give \$75,000 to a road from Augusta, Geo., by way of Greenville, S. C., to this place. Private subscriptions will give the road \$100,000, which is about subscribed.

LOS ANGELES, CAL.—The Brooklyn Heights Railway Company was incorporated August 11. It proposes to operate street railways, beginning at the Plaza and running to the eastern limits of the city.

LOS ANGELES, CAL.—Articles of incorporation were filed August 11 by the Depot Railway Company. The object is to construct street railways in this city. The directors are: James M. Davis, M. L. Wicks, J. F. Davies, W. H. Davies, and J. Bernard. Capital stock, \$100,000; amount subscribed, \$77,000.

DENVER, COL.—Address George Wirt Bowman about the proposed cable street railroad, which he is a promoter of.

KANSAS CITY.—The Kansas City and Sabine Pass Railway Company filed articles of incorporation August 17, and received a charter for the State of Missouri with a capital of \$2,500,000. Colonel Harrison M. James, of New York, is President, and Fred M. Day, of Brooklyn, Treasurer. The object is to build an air line from Kansas City to Sabine Pass, a distance of 700 miles.

RAILROAD.—Incorporated is the Oakland, Cal., Alameda and Laundry Farm Railroad Company. The line will be a broad gauge, running from Laundry Farm to Seminary Park Station on the line of the Southern Pacific.

PITTSBURG, PA.—A charter was issued August 23 to the Pittsburgh and Bellevue Passenger Railway Company; capital, \$15,000. The length of the road is to be four miles.

DUBUQUE, IOWA.—The Dubuque, Kansas City, and South-Western Railroad is incorporated by J. H. Farley, W. L. Bradley, F. D. Stout, and others, of Dubuque.

KNOXVILLE, TENN.—A company has been formed to build a street-car line to the West End.

LAWRENCE, KAN.—A charter was issued August 15 to the Meade Centre, Cimarron Valley and Trinidad Railway Company. Principal place of business, Hugoton, Stevens County, Kan. Directors: A. J. Crothers, L. E. Keiser, W. H. Green, G. S. Stein, and others. The proposed line is from Meade Centre to Trinidad.

DULUTH MINN.—The Duluth Terminal Company will build a line along the shores of St. Louis and Superior Bays, and across Superior Bay from Rice's to Minnesota Point, the main object being to enter Duluth. One proposition is to bridge the St. Louis about Fond du Lac.

SELMA, ALA.—The Selma Land Improvement and Furnace Company have completed arrangements to build the proposed Selma and Cahaba Valley Railroad. Work will doubtless commence at an early date.

LITTLE ROCK, ARK.—Articles of association have been filed with the Secretary of State for a road to be built by the Eldorado and Southern Railroad Company. The capital stock is \$300,000. The road will run from Camden to Eldorado, in Union, Ark., a distance of twenty-five miles.

MISCELLANEOUS.

NEW ORLEANS, LA.—Assistant Engineer Douglas has staked out four miles of levees to be built.

MILWAUKEE.—Norcross Bros., of Boston, are making a 14-ton pedestal for the 1,200 pound Lieft-Ericsson statue at the head of Martin Street. Mrs. Gilbert presents it to the city. The sub base is eight feet square.

TACOMA, W. T.—Dennis Ryan and a company of Eastern capitalists have begun the erection of smelting and reduction works in Tacoma. The capital stock of the company is placed at \$2,000,000, and the works are to turn out 400 tons of ore daily.

GOVERNMENT WORK.

WILMINGTON, N. C.—Bids for furnishing 5,000 tons stone for and dredging in Cape Fear River, N. C., received by Captain W. H. Bixby, Corps of Engineers:

(1) For furnishing 5,000 tons stone, opened September 1: John S. Howell, New York, \$2.17½ per ton delivered at works; George F. French, Rocky Point, N. C., \$1.66½ per ton delivered at Wilmington (\$1.84½ per ton delivered at works).

(2) For dredging, opened September 5: Rittenhouse Moore, Mobile, Ala., 13½c. per cubic yard, scow measure; Atlas Dredging Co., Wilmington, N. C., 13½c. per cubic yard, scow measure.

NEW YORK CITY.—Bids were opened at the Army Building, September 7, by George McC. Derby, Lieutenant of Engineers, U. S. A., for dredging in Raritan River, N. J. The engineer's estimate called for 4,800 cubic feet of dredging, 700 of which was rocky bottom. The following were the bidders: M. K. Pidgeon, New York City, dredging rocky section, \$14 per cubic yard in scow; remaining work, 47c. per cubic yard. Hartford Dredging Co., Hartford, Conn., rocky section, \$25; remainder, 60c. Elijah Brainard, New York City, rocky section, \$15.20; remainder, 49c.

THE bids for dredging Raritan and South Rivers, N. J., are considered too high, and the work will be readvertised.

ASHEVILLE, N. C.—The following bids for construction and repair of levees in Arkansas were opened September 2 by Captain William T. Rosell, U. S. Engineers:

J. M. Whitehall, Arkansas City, Ark., loops, Arkansas City to Amos Bayou, 2¼c. per cubic yard.

P. J. Lamb, Memphis, Tenn., loops, 20½c.; Panther Forest extension, 22c.; Leland ad loop, 10½c.; Brook's Break, 21½c.; Matthew's Bend, 21½c.

George Arnold & Co., Whiskey Extension, 39½c.; Brook's Break, 22c.; Matthew's Bend, 22c.

Timothy Sullivan, Memphis, loops, 32c.; Panther Forest, 20c.; Leland Loop, 19c.; Whiskey Break, 80c.; Brook's Break, 30c.; Matthew's Bend, 32c.; Grand Lake, 29c.

J. M. Namary, New Orleans, Matthew's Bend, 27c.; Grand Lake, 26c.

A. A. Arnold, C. F. Degans, Memphis, Tenn., loops, 21½c.; Panther Forest, 23½c.; Leland Loop, 22c.; Matthew's Bend, 24½c.

Andrews Bros., Florence, Ala., loops, 10½c.; Panther Forest, 10½c.; Leland Loops, 18c.; Whiskey Extension, 18c.

E. F. Verdit, Memphis, Whiskey Extension, 39½c.; McTighe & McKee, Memphis, loops, 21c.; Panther Forest, 10½c.; Leland Loop, 18c.; Whiskey Extension, 40c.; Brook's Break, 30c.; Matthew's Bend, 20½c.; Grand Lake, 22c.

J. J. Cooney, Memphis, Tenn., loops, 20c.; Leland Loop, 20c.; Matthew's Bend, 20c.

G. C. Dulany, Rosedale, Miss., Leland Loop, 16c.; Matthew's Bend, 20c.

Craig & Worthington, Lakeport, Ark., Leland Loop, 23c.; Whiskey Bend, 34½c.

W. R. Harney, Memphis, loops, 19c.; Panther Forest, 10c.; Leland Loop, 17c.; Whiskey Bend, 34c.; Brook's Break, 18c.; Matthew's Bend, 19c.

Craig & Graves, Sterling, Ark., Grand Lake, 26c.

Arnold & Flynn, Memphis, loops, 22c.; Panther Forest, 23½c.; Leland's Loop, 21c.; Whiskey Bend, 38½c.; Matthew's Bend, 23½c.; Grand Lake, 25½c.

Toppen & Fisher, Fruar's Point, Miss., Loops, 17c.; Leland's Loops, 17½c.

Daniel F. Hartwell, Memphis, Panther Forest, 22c.; Leland Loop, 18½c.

John B. McGinty, New Orleans, Brook's Break, 23c.; Matthew's Bend, 22c.; Grand Lake, 23½c.

Hugh Fernan, Memphis, Loops, 22c.

NEW ORLEANS, LA.—The following bids for 660,000 cubic yards of levees at Kempe and Deer Park were received by Captain D. C. Kingman, U. S. Engineers:

C. S. Jones and J. W. Ogden, Kempe, per cubic yard, 28½c.; Deer Park, 15.00c.

Robert M. White, New Orleans, La., none; 14½c. respectively.

Rogers & Ballantine, New Orleans, La., 30c.; none, respectively.

John S. McTighe & Co., Memphis, Tenn., 38c.; 17c. respectively.

John P. Kennedy, New Orleans, La., 34c.; 16½c. respectively.

Patrick Harrigan, New Orleans, La., none; 21c. respectively.

William Curry, St. Joseph, La., none; 19½c. respectively.

Albert G. Ober, New Orleans, La., none; 18c. respectively.

Michael B. McGarry, New Orleans, La., none; 16.74c. respectively.

Robert McNamara, New Orleans, La., 28½c.; 17c. respectively.

BALTIMORE, MD.—The following bids for metal-work for Harbor Island Light, N. C., were received by Captain J. C. Mallory, U. S. Engineers, September 3:

Colwell Iron-Works, New York, \$5,608; West Point Foundry Association, Cold Spring, N. Y., \$6,230; Phoenix Iron Co., Trenton, N. J., \$6,000; Allentown Rolling Mills, Allentown, Pa., \$5,600; H. A. Ramsay & Son, Baltimore, Md., \$7,950.

WILMINGTON, N. C.—The following bids for 5,000 tons of stone for improving Cape Fear Breakwater were received by Captain W. H. Bixby, U. S. Engineers, September 1:

John S. Howell, New York, N. Y., \$2.17½ per ton of 2,240 lbs. delivered at works.

George Z. French, Rocky Point, N. C., \$1.66½ per ton of 2,240 lbs. delivered at Wilmington (\$1.84½ delivered at works).

WOOD'S HOLL, MASS.—Owing to some informalities in the opening of bids for corrugated iron-work on the buildings for the Fisheries Commission they will be readvertised.

WASHINGTON, D. C.—Bids for erecting a house and appurtenances at Point Jupiter, Fla., for the use of the Signal Service, were opened September 1 by General A. W. Greeley, Chief Signal Officer, U. S. A., as follows:

W. G. Toomer, Jacksonville, Fla., \$4,000; W. A. Miller, Sanford, Fla., \$3,121.80; John & George W. Hufbauer, South Jacksonville, Fla., \$3,230; A. D. Pitts, Titusville, Fla., \$2,736.95; J. H. Caster, Baltimore, Fla., \$6,750; W. H. Sincell, Washington, D. C., \$9,000; C. C. Haight, Lake Worth, Fla., \$3,173.92; A. P. Dye, Lake Worth, Fla., \$2,743.

NEW YORK CITY.—Bids were opened at the Army Building, on September 7, by George McC. Derby, Lieutenant of Engineers, U. S. A., for dredging in South River, N. J. (under circular). The following were the bidders: M. K. Pidgeon, New York City, 40 cents per cubic yard; Jas. McSperritt, Jersey City, 35 cents per cubic yard; Hartford Dredging Co., Hartford, Conn., 30 cents per cubic yard. About \$40,000 is involved in the undertaking.

GALVESTON, TEX.—The following bids for protecting the shore of Arkansas Pass, Tex. (88,000 cubic yards of rip-rap), were received by Major O. H. Ernst, U. S. Engineers, September 2:

Gus Wilkie & J. W. Rickey, Austin, Tex., \$3.89 per cubic yard.

Louisiana Jetty and Lightering Co., New Orleans, La., \$3 per cubic yard.

T. H. Micklejohn, San Antonio, Tex., \$3.18 per cubic yard.

Charles Clarke, Galveston, Tex., \$3.35 per cubic yard.

A. M. Shannon & Co., Galveston, Tex., \$2.95 per cubic yard.

SYNOPSIS of bids for extension, Post-Office, etc. Peoria, Ill., opened September 1 by the Supervising Architect: John Angus, \$33,975; Jobst Bros., \$28,960.80; Larkworthy & Mencke, \$24,879.

SYNOPSIS of bids for materials, tools, and labor for plumbing and gas piping for Court-House, etc., Council Bluffs, Iowa, opened September 5 by the Supervising Architect: J. C. Bixby, \$1,543; A. L. Strang & Co., \$2,700.

THE SANITARY ENGINEER AND CONSTRUCTION RECORD.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1887, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 16. }
NUMBER 16. } PUBLISHED EVERY SATURDAY.

NEW YORK, SEPTEMBER 17, 1887.

LONDON, OCTOBER 1, 1887.

SINGLE COPIES, TEN CENTS.
Subscription, \$4.00 per year in advance, post paid. } IN AMERICA
SINGLE COPIES, SIXPENCE.
Subscription, 20s. per annum in advance, post paid. } IN GREAT BRITAIN.

THE SANITARY ENGINEER AND CONSTRUCTION RECORD, conducted by HENRY C. MEYER, is published every Saturday at 82 & 84 Fulton Street, New York. Its opinions upon all technical subjects are either prepared or revised by specialists.

TERMS, \$4 PER YEAR, IN ADVANCE.
Postage Paid.

OFFICE IN GREAT BRITAIN,
92 & 94 FLEET ST., LONDON.

TERMS, 20s. PER YEAR, IN ADVANCE. Postage Paid.
SINGLE COPIES, SIXPENCE.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE SANITARY ENGINEER AND CONSTRUCTION RECORD (New York), and crossed — & Co.

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzig, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, \$5; China, Japan, Sandwich Islands, Mexico and Cuba, \$5; South America, \$5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us promptly of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money order payable to THE SANITARY ENGINEER AND CONSTRUCTION RECORD.

When a change of address is desired, both the old and new addresses should be given.

THE CENTENARY OF STEAM.

We give space elsewhere in this issue to print a communication to the editor of the New York Times, intended, in this centennial year of the adoption of the Constitution of the United States, to ask the American public to do justice to the memory of the inventor of the high-pressure steam-engine, the value of whose work to mankind it is impossible to estimate. The Times says:

"On British soil there is a monument bearing upon its face the legend, 'Inventor of the Locomotive.' That proud title was never borne by Stephenson while he lived, nor was it, in fact, ever earned by him. On the contrary, that contemporary British journal which describes the running of the first train on the Liverpool and Manchester Railway, in that same number narrates facts which entitle an unfamed American to even greater honors. Just one hundred years ago this unhonored citizen of the Nation born in that year patented a device embodying the essentials of an invention surpassing Stephenson's or even Watt's. His invention was complete nearly ten years previous, and it was put to practical test in actual daily use several years before Fulton built the first steamboat, and a score of years before Stephenson built the 'Rocket' and made the remark about the cow. Certainly in this centennial year every American should be reminded that on our soil, and in the brain of a fellow-citizen, were first conceived ideas which, even in their stupendous development, have not surpassed the recorded conception of a man whose name ought fairly to be on every schoolboy's lips, but yet which is unfamiliar if not unknown to even well-informed adults. Foreigners concede his claims and erect false monuments to his inferiors. Yet probably it is now too late, and probably Americans are too preoccupied, for his fame, which should be their glory, to make fit headway. The reproach is theirs, but all the more it is useful to recall in this hundredth year what this man did for the world."

In republishing this communication, and thus calling attention to it, THE SANITARY ENGINEER AND CONSTRUCTION RECORD desires to suggest to the American Society of Mechanical Engineers the propriety of their appointing a committee to prepare a report that, besides doing justice to the inventors of that time, will contemplate a practical movement to be carried on under auspices of the society to secure a more general recognition of the services of Oliver Evans. Included in this should be a movement to secure a fund for the erection of a suitable memorial to be placed in Washington, the capital of the country, and on soil that was in his day a portion of the State that granted him his patent. To such a fund we would gladly contribute.

REMOVAL OF GRADE-CROSSINGS IN CONNECTICUT.

It is gratifying to learn that the directors of the New York, New Haven and Hartford Railroad have at last decided to adopt a more public-spirited policy in the management of that prosperous and wealthy road. THE SANITARY ENGINEER AND CONSTRUCTION RECORD has several times called attention to the murderous grade-crossings that have too long been tolerated by that corporation, and the several recent fatal casualties at these crossings between New York and New Haven and the public indignation thereat seems to have at last induced the management to prepare plans and specifications looking to their abolition. There are yet over one hundred of these crossings in the State of

Connecticut between the New York State line and New Haven, though in this State many of them have already been changed. This wise move, together with the proposed erection of new depots of good architectural design, the adoption of steam-heat and electric-lights as a substitute for the car-stove and kerosene oil, and other improvements in the road-bed now in progress, will soon result in its being held up as a model road, as the Pennsylvania for some time has been.

DEATH-RATES OF DIFFERENT CLASSES.

WHATEVER one may believe as to the truth of the declaration that all men are born free and equal, it must be admitted that they do not remain so. If any evidence of this were needed, it could easily be furnished on one point—viz., that the death-rates of different classes of men are not equal; that the chances of life, and the probable length of life, are very different in what are known as the upper, middle, and lower classes. For example, Dr. Farr's life-table of England, based on the data for the 17 years 1838-54, gave as the mean duration of life of males about 40 years. Mr. Humphreys' life-table, based on the records of the five years 1876-80, gave the mean duration of life of males as 41.9 years, showing marked improvement. Taking the healthiest districts in England, in which the mean annual death-rate did not exceed 17 per 1,000, Dr. Farr constructed a healthy district life-table from the records of 1849-53, which gave 48.6 years as the mean duration of life for males. All the above life-tables include all classes of population. The life-tables of the English peerage show a mean duration of life of 52 years for males, and Mr. Ansell's table for the upper classes gives the mean duration of life as 53.1 years. These differences, as pointed out by Mr. Humphreys, are largely due to the low death-rate among children under five years of the peerage and upper classes, since the annual death-rate of children under five years of age ranges from 65.7 per 1,000 by the general table, 39.4 by the healthy district table, and 28.2 by the upper class table, to 20.7 by the peerage table. There are no life-tables for the working classes from which we can make corresponding comparisons. The best data that we have for this purpose are some of the English statistics with regard to mortality by occupations, and some statistics of class mortality published by Dr. Grimshaw, the Registrar-General of Ireland. All of these are discussed in a carefully prepared paper by Mr. N. A. Humphreys, published in the journal of the Royal Statistical Society for June, 1887, under the title "Class Mortality Statistics." By Dr. Grimshaw's figures the annual mortality among children under five years of age was, per 1,000, for the professional and independent class, 22; the middle class, 59; the artisan class, 71; and for the general service class, 110. Mr. Humphreys remarks that this wholesale slaughter of the sickly children of the working classes does not increase the vitality of the survivors in the next age period (5-20 years), the death-rate of which is, per 1,000, for the professional and independent class, 3+, and for the three other classes, in the order above given, 8, 9, and 11 per 1,000.

Now, in view of these figures, and of many others of similar tendency which may be found in the papers above referred to, it is evident that one of the first things needed as a guide for intelligent effort to improve the condition of the working classes is definite and positive information with regard to their death-rates and the causes of death which chiefly affect them. In this country we have practically no data for class mortality statistics, and with our present machinery for collecting vital statistics, whether State or municipal, it is not possible to obtain such data as would be required to settle these important questions.

The trades-unions and the Knights of Labor could do it if they began in the right way, by getting expert advice as to how to do it, and when it was done they would have some definite foundation for a statement of their case—something that would show where the shoe pinched. We commend this subject to the consideration of the managers of trades-unions, and the promoters of reform in general; it would have more practical effect than all the denunciations that can be produced.

THE SANITARY ENGINEER AND CONSTRUCTION RECORD, when the contracts were let, predicted the work would not be done in the time specified. The failure, however, to begin the Quaker Bridge Dam makes the time of completion of the aqueduct of secondary importance, since it is likely to be finished before it can be fully utilized.

BRITISH CORRESPONDENCE.

THE scheme of the enterprising corporation of Birmingham for supplying power by compressed air for driving-engines, etc., is taking definite form, and the plant is nearly complete. The corporation's engineer states that for a nominal eight-horse-power engine it is estimated that the cost of supplying necessary power would be £13 (\$62.40) per I. H. P. per annum, as against £17 (\$81.60) on the old system.

A PECULIAR engineering scheme is under consideration at Southport in Lancashire. The place is a seaside resort, but labors under a very great disadvantage, inasmuch as at ordinary tides the sea does not come to within two miles of the marine parade. To remedy this, it is proposed to erect at the ordinary high-water mark, between the sea and the parade, a sort of breakwater, with a view

engines and staff throughout London were present at the fire, and that had another fire of any magnitude broken out there was not sufficient force to grapple with it. A penny-wise and pound-foolish policy is adopted, whereby in any case in which the first few engines are run out of headquarters, the men have to rush out to various contractors, trying to get horses to horse the remaining engines, thereby losing valuable moments in the early stages of a fire, which are of course irrecoverable.

LONDONERS are promised additional comfort throughout the winter months in public conveyances by the introduction of the electric-light in tram-cars and omnibuses. There is a very enterprising company—namely, the London Road Car Company—which has only been upon the road for some eighteen months or two years, but which has already been able to force the London General Omnibus Company, hitherto, comparatively speaking, monopolists, to lower their rates. Several vehicles of this Road Car Company have just been fitted with the electric-light, and the conductors assert that it works very satisfactorily, and gives them no trouble.

In a recent paper contributed to the *Zentralblatt der Bauverwaltung*, by Mr. R. Hinkeldeyn, on "Building

RESIDENCE OF JOHN CALVIN STEVENS, PORTLAND, ME.

CHICAGO SEWAGE PROBLEM.

We have a communication from Mr. Gordon Nott, whose scheme for dealing with the sewage of Chicago was criticised in our issue of August 20. Besides being too long for publication, there is no important information given concerning what he proposes to do beyond what we gave in the former article.

We are still of the opinion that the most practicable plan for dealing with the Chicago sewage is by a canal of sufficient capacity to dilute and remove it, as proposed by the commission of engineers appointed by that city and explained in our former article.

THE TIME EXTENDED FOR COMPLETION OF THE CROTON AQUEDUCT.

THE Croton Aqueduct Commission have extended the time in which O'Brien & Clark and Brown, Howard & Co. were to complete their work on the New Aqueduct to eight months from September 20. The Commissioners explained the extension of time to the contractors by the statement that unforeseen obstacles had been met with in making the tunnel, and that it had been decided to line the tunnel with brick after the original contracts had been awarded.

to ponding the sea-water facing the parade in a sort of inland sea. The proposed breakwater would be made sufficiently wide at the top to form a parade or a drive, and would be in the shape of a continuous tunnel, provided on the seaside with a sort of lip or trough communicating with the tunnel by numerous inlets. This trough, which is on the outer slope of the breakwater, will run its whole length. The sea, rushing up the side of the slope, would deposit the water in the trough, whence it would flow into the tunnel under the breakwater, by which it is conducted through syphons into the inner basins of the artificial sea. To provide against evaporation, it is proposed to have a pump driven by a wind-motor and a fan, the pump being capable of delivering 20,000 gallons per hour. The scheme is the combined invention of Mr. E. Lightowler, of Southport, and Mr. B. H. Thwaites, C.E., of Liverpool. It is assumed that in the course of passing from the sea proper to the inland sea, any organic matter would be deposited in the tunnel of the breakwater, whence it could be flushed out by a sluice-valve at the end.

THE recent large fire at Whiteley's, the 'Universal Provider,' has again emphasized the state of affairs with regard to protection by the fire-brigade, which is distinctly deficient in quantity and material. It is stated by the fire-brigade authorities that the bulk of the

Construction," with no small measure of praise of the great care and excellent work done in sanitary engineering in this country, also speaks of the recently established chair of sanitary engineering at Columbia College, and thinks it a move in the right direction, and one that will give excellent results.

OUR SPECIAL ILLUSTRATION.

A MANUFACTORY.

THE subject of our special illustration is a building for manufacturing purposes, owned by Mr. C. De Hart Brewer, 100 feet on Washington Street and 265 feet on Herbert Street, this city. The ornamental bands are of Philadelphia brick and terra-cotta; common selected Haverstraw brick used elsewhere. Jambs of all openings of rounded "Peerless" brick. The cost was \$82,000. The architect was Henry R. Marshall, of New York.

OUR VIGNETTE ILLUSTRATION.

THE subject of our vignette illustration is the house of Mr. John Calvin Stevens, architect, Portland, Me. The first story is rough brick; all above shingled and stained. Finish mostly whitewood, stained. Hardwood floors on first story. Cost, \$4,600.

(Continued from page 69.)

STABLE-FLOOR CONSTRUCTION.

THE following letter from Captain Pond, United States Army, suggested a useful line of inquiry. A number of stables in New York and Boston were therefore examined, and the data herewith given is the result of that investigation. We should be glad to have any of our readers supplement this information or indicate to us where we may obtain further data on this subject.

FORT RILEY, KAN., August 4, 1887.

SIR: Would it be asking too much to request you to inform me, either by letter or in your columns, of the most approved method of flooring stables for a large number of animals? I am to construct a number of stables for cavalry and artillery. It is desired to floor them to secure drainage and prevent dust. I have two methods in view: (1) To floor throughout with 2-inch yellow pine; (2) to concrete throughout, Barber asphalt the drives, and floor the stables. The cost will be about the same. Which is the best, or are there better methods? Of course I intend to have a complete system of drainage, with suitable flushes, traps, etc. An answer as above will be much appreciated. Respectfully yours, GEORGE E. POND, Asst. Qr. M., U. S. A.

MATERIALS USED FOR FLOORS OF LARGE STABLES IN NEW YORK AND VICINITY.

Adams Express Company's Stables, Jersey City.—Stalls are provided for 190 horses. The first floor is laid with cement-concrete in a monolithic sheet. This has cracked in many places, which would have been prevented by laying it in sections 6 feet square. A number of stalls are located on this floor, and also several box-stalls, which are 10 feet square.

The second floor is supported on iron columns and girders, on which the wooden joists rest. The floor is composed of yellow-pine planks 3 inches thick and calked in the same manner as a vessel. The stalls are 9x5 feet, with gutters for drainage provided outside of the partitions by cutting a groove in the floor. This connects with drain-pipes about 33 feet apart, which are carried down the iron columns to the sewer. This gutter is covered with boards laid down loosely flush with surface of floor, and made in sections of about 8 to 10 feet each. The floor of stalls and alleyway between slope toward these gutters.

The stall floor is covered with slats made of spruce about 2 inches thick and from 3 to 4 inches wide, fastened together by cleats on under surface, which raise it from floor, permitting urine to flow freely to gutters. The space between foot of stalls is about 10 feet wide, and alleyway at head of stalls is 4 feet wide, the latter utilized when feeding. The drains connect with gutters by means of square iron frames 9x9 inches, in which is fitted a perforated lid 7 inches in diameter. There is no complaint made of horses slipping.

United States Express Company's Stable in Jersey City.—Their building is of brick and will accommodate 300 horses. First floor laid with plank and utilized for storage of wagons and for office. The second floor is supported on iron columns and girders on which the wooden joists rest. On these joists 3-inch plank is laid for the floor. On this floor is laid two thicknesses of prepared felt and covered with Neuchatel asphalt, which is laid with smooth surface in the stalls but corrugated in all passageways between them. The stalls are about 9'6"x4'8", with gutters made in the asphalt at foot of stalls, which are connected with drains similar to those described in the Adams Express stables. In a portion of the passageways where horses are compelled to turn short, sand is sprinkled, whenever horses are smooth-shod, to prevent slipping, but sand is not used when shoes are well calked. A recent fire destroyed all of the wood-work of second floor and everything above it, except the brick walls, but left every part of this floor intact that was covered with this asphalt. The first floor is now used the same as before the fire. Two

more stories will soon be added and asphalt used throughout. The superintendent stated that he would not use any other material, and that the whole building would have been a total loss had the second floor not been protected with this material.

Riding-School Stable, Fifty-eighth Street and Seventh Avenue.—Both wood and Seyssel asphalt are used here for floors. The stalls are covered with slats made of oak two inches thick, and there are covered drains at foot of stalls.

American Express Company's Stable, Forty-eighth Street and Lexington Avenue.—This building is new, composed of brick with second floor supported on iron columns and girders and provided with a large elevator. The stalls visited were in the basement and will accommodate several hundred horses. This floor is made of cement concrete or artificial stone, smooth on surface in the stalls, and corrugated in 4-inch squares in all passageways. The stalls are 4'8"x10', with depressions for drainage in each stall about two feet from rear end of partitions, the floor surface in and adjacent to this depression made sloping to it. In each depression is set an iron frame 9x9 inches, which supports a circular perforated lid seven inches in diameter connecting with drains and thoroughly trapped.

Floor of stables is covered with spruce slats made in three sections for convenience in cleaning, the forward

half in one piece and rear half in two parts, divided longitudinally.

There was no complaint of horses slipping, and drainage appeared to be perfect. The sloping passage to main floor for horses covered with five inches of tan bark.

Jacob Rupert's Brewery Stables.—These are small one-story frame buildings, with stables on surface of ground.

The foundation is made of concrete covered with 3-inch spruce plank. The stalls are 4 feet 8 inches to 5 feet and 10 feet long, with board drains outside of stalls covered with boards flush with floor. Floor of stalls covered with birch plank.

The foreman states that they had used both artificial stone and asphalt, but abandoned them on account of their slipperiness.

De Kalb Avenue Horse-Car Stables, Brooklyn.—These stables will accommodate 500 horses, and the floor is covered with Seyssel asphalt, having a smooth surface throughout the whole second floor, where stables are located. Stalls 5x10 feet, and passages 7 to 10 feet wide. The surface of both stalls and passages slope toward gutter at foot of stalls. Floor of stalls covered with spruce slats.

But little trouble is experienced with horses slipping, and to prevent any possible chance of their doing so, the surface of passages are kept sanded.

The foreman of stable is with the material.

SUMMARY OF INFORMATION OBTAINED IN NEW YORK.

In all stables where first cost of construction is considered only spruce plank is used, as it at all times gives a firm footing for horses, and is convenient to repair when stalls are located on first floor; but where leaks occur when stalls are on the second floor they are often very expensive to repair, as any fluid will frequently show itself at a long distance from cause of trouble.

Yellow pine is not favored, as the urine causes any sappy portion of planks to decay quickly.

Concrete or artificial stone is but little used on account of slipperiness after long use, as its wearing surface becomes smooth, the same as paving-stones. The American Express Company's stables are new, and therefore not thoroughly tested.

The only asphalt used in this vicinity is the natural rock. The weight of testimony of those who have used Seyssel and Neuchatel rock asphalt appears to be in their favor.

The only objection is to its slipperiness, but those now using it and stabling the greatest number of horses favor it. A little sand sprinkled on surface removes all fear of horses slipping when smooth-shod. It has many points in its favor—imperviousness to water, and is not affected by acids of urine, can be cleaned with a minimum amount of labor, and is fire-proof.

It does not affect horses' hoofs, as its constituent elements are not evolved except at a high temperature.

BOSTON.

Newbury Street Club Stables.—Peabody & Stearns, Architects.—In this stable the stalls are located on the second floor, over the carriage-rooms.

There is a line of stalls down each side of the building and one line down the middle.

The stalls are 5x9½ feet. The sides and front to a height of 4 feet 4 inches are hard pine, 2-inch plank; above this is an iron guard, 2 feet 8 inches high, of ½-inch round iron. At the head of the stall, on the left, is a cast-iron feed-box in two sections, one being covered and set 3 feet 4 inches from the floor. In the right-hand corner is the hay-rack set at the same height, to be eaten out of from the top.

The under floors of the stalls are set somewhat lower than the rest of the floors, and the areas concreted over. Each section of three stalls is dished toward the centre of the middle ones, where is set a cast-iron cesspool and grating connected below the floor to the soil-pipe. The surface of the concrete is finished off in asphalt.

The line of floor-joists at the head and foot of stalls have a wrought-iron angle-iron bolted to them, on which rest hard pine frames, which are mortised together, and

form the support of the stall floor. Down the centre of the stalls are placed two sections made up of 3x5½-inch hard pine bolted together, with cast-iron drainage-grooves set between each; these are sloped from each end to the centre of the stall. The rest of the stall is floored with 1¾-inch hard pine laid in 6-inch strips, bearing true on either side of the middle and straight-wise at the head.

The 3x5-inch portions are in two sections 21½x30 and 21½x57 inches. By raising the shortest section in the middle one of three stalls, access is had to the cess-pool below. The cast-iron grooves are one inch square outside, and the 3x5½-inch hard pine sticks have to be rebated on an angle, so as to give the necessary fall to this groove, which is 2 inches in the 4'x9" strips. On the 2'x6" strips the gutter is but 24 inches, leaving a 6-inch space at the middle for the drippings to fall through to the asphalt surface, from which it flows to the cesspool.

This building was only put up this year, and has not yet been used, so that the working qualities of the arrangement has not been tested.

(See sketch.)

Highway and Fire Department Stable at Newton.—In alterations, a floor of ¾-inch spruce was first laid over the whole area, on which tarred sheathing-paper was spread. An upper floor of best quality 1½-inch maple was laid over this, well planed, jointed, and made tight; this extended to the gutters which ran along the rear of the stalls. In the stalls A. F. Hall's patent cast-iron stall bottom was used, fitted with maple plank, and the rest of the stall fitted out with 2-inch maple laid crosswise at the head of stalls. The cast-iron gutter at the foot had a maple-plank cover. This Hall's patent is a casting some five feet long, the upper surface of which has projecting ribs into which are fitted 2x4½-inch maple planks, and between which are the drainage grooves which are sloped toward the rear of the stall. It is some little work to fit in the plank so as to have them tight, and if not tight, urine will get in and rot them from below.

In this particular stable the manure is kept in the basement right below the stalls. In order not to soak down the manure with all the floor washings, lead pipes were attached to the outlets of the gutter, and bent so as to deliver opposite and a little above an open T on a line of drain-pipe suspended from the floor joists. The ordinary dripping would thus fall on the manure, but when running full from floor washing the stream would strike in the bell of the T and be carried off in the drain, which was trapped at the wall.

A drying-room for bedding was also arranged in this stable. It was a room partitioned off next to the outside wall with two windows in it and opening near the floor

Metropolitan Horse-Car Company's Stables.—The Bartlett Street stables contain some 350 stalls. The car-shops are located in an adjoining building, and some additional accommodations for horses are being prepared at the present time.

Mr. Isaac Randall, who has charge of the car-shops and the repairs and additions being made to the stables, states that at one time the different car stables were fitted with iron drainage gutters in the stalls, but owing to the extra expense of preparing and getting out the stock for them they were abandoned some years ago.

The method now adopted is that which is being used in the new stalls at the Bartlett Street stables, which is as follows:

The whole area of the stables, which are located over the car-depot, is decked over with 3-inch plank, thoroughly calked with oakum and made water-tight. This forms the surface of the passageways.

In the stalls a boarding of inch spruce is put on and nailed tight. Over this is laid a floor of 2x4-inch spruce laid crosswise at the head of the stall and lengthwise on the rear 5 feet. This rear part is laid with a space of ½ an inch between each plank, forming a drainage groove, terminating in a hard pine gutter which is set in the floor along the rear end of the stalls.

The 2x4-inch spruce planks are found to wear out from the pawing and scraping of the horses' feet long before the spruce boarding below it is rotted by the urine and manure which get into the drainage grooves; and several sets of the 2x4-inch are used up before it becomes necessary to replace the boards below.

No doubt hard wood, elm or maple, is much better than spruce for the stall floors, but it is much more expensive and much harder to obtain. It must be got out a long time ahead and kept on hand to be used in repairs, as it cannot be found on the market at any time as the spruce can. Maple stock cost two and a half times as much as the spruce and is much more work to put down, and the experience with the company is that spruce is more economical.

The stalls are built in double rows facing each other, the sides and head partitions being of plank and run up some 8 or 9 feet. But the space under the feed-trough is left open for purposes of ventilation and ease in cleaning out. The trough is of spruce plank, with an iron strip screwed on the upper edge.

Most of the stalls are double, intended for a pair of horses.

At the South City stables, for highway horses, some 150 horses are kept.

Here the stalls are in two rows facing each other, but with a wide passage of some 10 to 15 feet between. The

gutter which runs along the rear of the stalls. This gutter is left open at the South Stables.

At the Highland Stables the gutter at the foot of stalls is covered with plank, and the plank in the stalls are 2x6-inch spruce. In some places where the floor has been renewed the new 2x6-inch plank has been laid over the old, making the drainage grooves come over the middle of the old planks. At this stable there is a double plank floor over the whole area on top of the first rough boarding.

The stables of the Health Department, near the jail, on Charles Street, are also arranged in a similar way.

These stables are very high studded and well supplied with windows. The stalls being out on the floor, the ventilation is good.

The bedding in the daytime is kept in an iron crib along the outside walls in the rear of each stall, is easily accessible, out of the way, and gets a pretty good airing.

In the Fire Department engine-houses hard-wood floors are used throughout, hard pine or maple. The stall have hard-wood strips 2x4 inches set ½ inch apart and iron gutter along foot of stalls only.

In most of the large livery stables and cab stables hard pine is also used for the floors and stalls, with wooden drainage gutters, and cast-iron gutters at foot of stalls; usually covered by planks removable in sections at each stall.

CARRYING WATER-MAINS ACROSS A RIVER.

KALAMAZOO, MICH, August 26, 1887.

SIR: I recently saw an article in your paper, dated July 9, 1887, page 158, over the signature of J. H. Harlow, of Pittsburg, relative to my paper on "River Crossings for Water-Mains,"* prepared for the last meeting of the Michigan Engineering Society. Mr. Harlow seems to think that there was no call for that paper. It was prepared by request of the president of the society. Still I should not have offered it had I not felt that there was great need of a better knowledge relative to this kind of work. I think if Mr. Harlow will study that paper in a different spirit, and until he fully comprehends it, he will certainly greatly profit by it.

To compare the crossing of the St. Joseph River at Elkhart, Ind., with the crossing at Grand Rapids, Mich., is simply ridiculous. In the former case the river is only about one-third the width of the Grand River, and the river-bed is gravel instead of rock, as at Grand Rapids. It would have been very easy to have made a trench in the river bottom at Elkhart and covered the pipe, instead of which it is laid without any trench at all, and lies fully exposed to sight, and is in great danger of destruction by ice every winter. At Grand Rapids the pipe is thoroughly bedded in the rock and covered. The

under each window, closed by slides. Just above these openings was the screen on which the bedding was spread. This was an iron frame in sections, with wire netting ½-inch 2x4 mesh, hinged at side opposite to windows, so as to be turned up in order to sweep out the litter below. In this way a current of air could be passed upward through the bedding and thus dry it off.

In some of the stables here Jones' drainage grooves are used. These are cast-iron grooves made in lengths of five to seven feet, and sloping from nothing at one end to an inch or 1½ inches in depth at the other. For these the floor of the stall is laid level. Maple or hard pine plank 2x4 or 2x6-inches is rabbeted out on each side to receive the flange of the groove, which is set with elastic cement. This keeps all liquid from accumulating on the under flooring.

horses are all fed from the head of the stall. For this purpose the front of the stall is planked up only 4½ feet and above is a netting two feet high in wrought-iron frame, which is hinged at bottom. This is turned down for the purpose of shoveling in the feed from the feed-tray, which is on wheels, into the feed-trough in the stall, then the screen is raised up again fastened by bolts to the posts. These screens are of ½-inch wire, woven in 2x4-inch diamond meshes. The floors is laid on 3x12-inch joists, 16 inches on centres, with rough boarding, on which a hard plank floor is laid. In the stalls 2x4-inch spruce planks are laid on top of this, set one-half an inch apart in the rear five feet, and close together in the rest of the stall. These floors have to be furred up so as to slope back and allow the drainage grooves to discharge into the cast-iron

manner of putting the pipe together and lowering to place at Elkhart was very different from the plan adopted at Grand Rapids, and was, I think, quite novel (?). Had it required "two" men "to stand in the water and hold each trestle" while the pipe was being laid, I should have been obliged to have employed 160 extra men during the progress of the work, but I arranged my false work so that it would stand alone, without which it is impossible to do such work properly. It would have been very easy to have done a first-class piece of work in crossing the St. Joseph at Elkhart had the work been properly planned and executed, but, as it is, no reputable engineer ought to have accepted it. Had the work been done like the

*See THE SANITARY ENGINEER AND CONSTRUCTION RECORD, dated June 18, 1887, page 71.

Grand Rapids work, there would have been no breakages and leaks to repair, as has been the case at the Elkhart crossing, requiring much trouble and expense in coffering, etc. I had nothing to do with the Elkhart water-works, except to locate the source of water-supply and make the plans for its development.

Fairbanks, Morse & Co., of Chicago, obtained a franchise, and planned and built the works, J. H. Harlow & Co. doing the work for the company by contract.

Respectfully, W. R. COATS.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

No. XXI.

(Continued from page 291, No. XX.; Article XIX. on page 123.)

DERRICK FOOT-BLOCK AND SHEAVES AT SHAFT 14 ON THE NEW CROTON AQUEDUCT.

SHAFT 14 on the New Croton Aqueduct is situated easterly of Ardsley, a station on the New York City and Northern Railroad.

A depression in the contour of the natural surface on the line of the aqueduct at this point is great enough to bring the crown of the arch near the surface, and therefore permitting the masonry to be constructed in open cut for several hundred feet. At the point where this derrick is located the brick arches have been completed and a portion of filling put in place. To facilitate the

FIG. 72.

removal of material from tunnel headings as the work extends from this point, a small shaft has been built with a height of about 45 feet above grade. The derrick illustrated in Fig. 72 is located over the aqueduct and adjacent to this shaft, for the purpose of elevating the car-box (filled with excavated material) to the surface and deposit contents for filling over the arch. The car-boxes are fitted to trucks in a manner to permit them to be easily detached. The boilers and compressors are situated about 100 feet distant, and a small Lidgerwood hoist adjacent to this shaft is operated by utilizing a portion of the power generated in the plant mentioned.

Before describing the foot-blocks, the large sheaves used on this derrick will be noticed. While there is nothing novel in their construction, yet the large size, two feet in diameter, is noteworthy. The advantage claimed for these sheaves, indicated by *s* in Figs. 72 and 73, are increase of power on account of the diminished friction over ordinary sheaves of eight and ten inches in diameter when wire rope is used. The wear on wire rope is less and the strands are not cut as quickly; the rope, therefore, will bear longer service.

Figure 73 shows the details of the derrick foot-block. No. 1 represents a side view of the foot-block and end of socket-plate, and also the position of lower sheave at *s*, indicating the relative position of the latter in connection with foot-block.

The derrick is supported on four short timbers, each 4 feet long and 12 to 14 inches square, for the purpose of fitting the lower sheave under the mast in a position that

will permit the rope to be operated through the pivot, which is placed between the mast and boom, and not under the mast, the usual position on ordinary forms of derricks now in use.

At *h*, No. 2, is shown plan and section of socket-seats which support the mast. This socket is $7\frac{7}{8}$ inches, and 7 inches in depth. The socket in which the boom rests is indicated at *e*, with dimensions similar to socket for the mast, having a curved surface in a portion of the section, to permit the boom to be fitted easily, and revolved in a vertical position. A pin $1\frac{1}{2}$ inches in diameter is inserted through the plate and boom, holding the latter secure in position. The sides of the casting are three-quarters of an inch in thickness. The pivot is located at centre of foot-block, extending $2\frac{3}{4}$ inches below bottom of socket, and is $4\frac{7}{8}$ inches in diameter, having a hollow centre, *j*, $3\frac{1}{4}$ inches in diameter, through which the rope passes to lower sheave which controls the direction to the hoist-engine.

A projection is made from socket *h*, permitting a $\frac{3}{4}$ -inch rod to be inserted, which can be extended a few feet up the mast, to strengthen and hold it more secure in position on the plate if desired.

No. 3 is a plan and section of socket-plate, which is 8×15 inches and $1\frac{1}{4}$ inches in thickness. This plate has a projection of $1\frac{1}{2}$ inches in depth, and is $7\frac{1}{2}$ inches in

FIG. 73. DETAILS OF DERRICK FOOT BLOCK AND SHEAVES. USED ON NEW CROTON AQUEDUCT, N.Y.

By using this foot-block a mast and boom can be fitted for work in much less time than with ordinary pivot, as it is not necessary to bore a hole in the mast several feet in length for the rope to run in, as required in the common form of derricks, and tools for boring are not always to be had when needed. These foot-blocks are in use at other points on the aqueduct, and we saw them on the new Harlem bridge. They were invented by Mr. P. Kelly, of Poughkeepsie, N. Y., and are made by John Claffy, of 48 Dey Street, New York.

WOOD PAVEMENT IN THE METROPOLIS.*

Durability.—One of the most important factors in connection with durability is the amount of traffic to which the pavement is subjected. As the author has been unable to obtain complete information thereon he has had to rest content with the available figures, and has reluctantly omitted results and comparison of other important streets. Table III. (see page 434) shows (1) the daily traffic weight per yard width; (2) the depth of annual wear of wood; and (3) the annual wear of wood as reduced to a standard of traffic equal to 750 tons per yard width daily, or 235,000 tons per annum, exclusive of Sundays. It is gratifying to

length on the bottom, to be fitted into supporting timbers. This projection has a hollow centre at *j*, corresponding with opening in pivot. This plate is bolted to timbers to prevent any movement when derrick is revolved. The pivot rests and revolves in socket *h*, which is $1\frac{1}{4}$ inches in depth and 5 inches in diameter. A groove is shown at centre of plate, which can be used when the pivot requires lubricating.

The rope is run from first sheave above foot of mast, through this pivot, passing around lower sheave and thence to the hoist-engine.

The rope that controls height of boom can also be passed through this pivot, if desired, and operated with steam-power by fitting double sheaves below the mast.

The advantages claimed for this device are the arrangement of hollow seats, indicated by *e* and *h*, for supporting the mast and boom in connection with a socket plate, with pivot between mast and boom, thereby transferring centre of gravity from centre of mast to a point where the two will nearly balance each other, and permit a derrick to be revolved with facility in any position, having only a minimum change in position of rope, which is worthy of consideration, particularly when wire rope is used.

The arc of contact being longer in the sheaves described than in ordinary size in use, the utility of the large sheaves is more apparent for wire rope than with manilla.

remark that there is a growing tendency to make observations and keep records of traffic weight, wear, and cost, and it is only by these means that reliable data can be obtained. It is to be hoped, therefore, that both local authorities and wood-pavement companies will institute the desired inquiries, by which means much valuable experience and knowledge will be gained. The comparative annual wear reveals several inconsistencies. For instance, the wear of the asphaltic pavement in Fleet Street with the maximum traffic weight, or 24th on the list, is but 16th in point of wear, whereas the same system with the 13th and 9th traffic weight positions, takes the high places of 24th and 23d in wear. Lloyd's pavement in Regent Street has an 8th traffic-weight position, but a 20th in wear. The wear of the improved, of Henson's, and of the plain pitch-pine pavements compares favorably in all cases with the traffic weight. The lesson to be drawn from these figures would appear to be that the asphaltic and Lloyd's systems are not successful; and the author cannot help regretting that Regent Street should have been paved upon these particular systems. The pavement in Parliament Street is stated to have worn $\frac{1}{2}$ inch only in three and a quarter years, but it must not be forgotten that its real wear has scarcely begun, and that the traffic weight is high. Should its life be eight years (which is extremely doubtful), it would take a higher position, as the annual cost would probably be 1s. 6d. per square yard.

It is interesting to notice that some pavements have exhibited a considerable degree of durability and have had

*A paper by George Henry Stayton, Assoc. M. Inst. C. E., and printed in the Minutes of the Proceedings.

a tolerably fair life. In the author's table the pavements and periods under the headings "actual" life relate to accomplished facts, while several under the heading "estimated" have already nearly realized the life allotted to them. In other cases the estimate is given after inspection and measurement or inquiry. The number of the pavements is necessarily restricted in consequence of the absence of traffic-weight records.

*Weight of traffic taken from Mr. Howarth's paper in these instances.

The author inclines to the opinion that it is not desirable to lay blocks of a greater depth than will provide for a life of seven years, as very few pavements retain a good surface after about six years' wear. In the case of the pavements previously described which have attained a greater life than seven years, it is proper to explain that those periods were only insured by the execution of frequent and somewhat costly repairs. For instance, a considerable number of new blocks, of depths varying from 3 inches to 5 inches, according to the extent of wear, had to be inserted in most cases, while in others the old blocks were taken up, reversed, and relaid. These operations, however, are very unsatisfactory, both in appearance and ultimate result. Experience consequently suggests that if 5-inch blocks were adopted instead of 6-inch, it would be preferable; and the author favors the opinion that the smaller depth would be found not only sufficient, but more economical and suitable, and would obviate much patching. Five-inch blocks are cheaper by 10s. per thousand, and it is estimated that in the first cost and twice renewal of a pavement which has an annual traffic of 750 tons per yard width, there would be a reduction in cost of 1s. 6d. per square yard in fifteen years, or 1 1/4d. per square yard per annum. Even if the average annual wear of 6-inch blocks should prove to be very little, after seven years' wear it will generally be found that the surface is irregular; but considerable hesitation is always shown before local authorities order the wood to be renewed, for fear that they may be accused of waste or extravagance in removing blocks which still retain a good depth, although they show a considerably worn and bumpy surface. In short, therefore, 5-inch blocks would give as good a surface and pavement as 6-inch blocks; there would be less waste of timber in renewal, and on the whole there is little doubt that pavements would be kept in a better condition. Blocks having a depth of 5 inches only have been laid in Oxford Street, Leadenhall Street, and Aldersgate Street, and in Kensington a large area has been laid on this system; and the result so far appears to be satisfactory.

The author has obtained numerous specimens of blocks from various streets, and he submits nearly sixty, which have been taken from Regent Street, Pall Mall, Cannon Street, Oxford Street, Ludgate Hill, Brompton Road, Praed Street, Sloane Street, King's Road, and Fulham Road. It will be observed that the maximum depth of wood is from King's Road (pitch pine), which is 5 3/4 inches after four and a half years' wear, and that the minimum is from Oxford Street (near Rathbone Place), which is 1 3/4 inches after six years' wear.

(TO BE CONTINUED.)

A GRANITE shaft recently quarried by the Bodwell granite Company in Vinalhaven is the largest piece of stone ever quarried on earth, and if erected will be the highest, largest, and heaviest single piece of stone now standing or that ever stood, so far as there is any record. It considerably exceeds in length any of the Egyptian obelisks. The shaft is 115 feet long, 10 feet square at the base, and weighs 850 tons.—Rockland (Me.) Opinion.

HOT-WATER HEATING AND FITTING.

BY "THERMUS."

No. XI.

(Continued from page 409.)

FLOW OF WATER THROUGH MAINS OF AN APPARATUS.

(1.) To find the total head when the quantity of water to be passed and the size and length of pipe is given.

From the foregoing tables and what has been said about friction and resistance in pipes and fittings it is not a very difficult matter to determine the amount of head required for any particular set of mains, when the quantity of water passing and the size and length of the pipes are known, as we have simply to refer to the tables.

Say we have a line of straight and level 4-inch pipe, 100 feet long (no provision made for easy entry), passing 50 gallons of water per minute, from the side of a tank or boiler, what will be the total head required? By Table III. the head for friction of 4-inch pipe passing 50 gallons of water is .243 of an inch for 10 feet of length, and for 100 feet it is .243 × 10 = 2.43 inches. Then by Table II. it will be found that 1/2 inch of water-head will be required to move 51.94 gallons of water through a 4-inch pipe without considering the head for friction, which gives us a total of 2.43 inches for friction, plus .5 inches for velocity, = 2.93 as the total head necessary to move 50 gallons of water through a 4-inch pipe 100 feet long. In other and fewer words, the head for friction is directly as the length of the pipe in 10-foot lengths (according to the tables here given), and the head for velocity is a constant, irrespective of length.

If we now put one common elbow into this pipe, such as shown in Fig. 22, we will proceed as in the example given above, but instead of considering the length of the pipe as 100 feet, we will consider it 100 feet + 100 diameters for elbow; which will be 400 inches, or 33.3 feet, making the resistance equal to what it would be in feet 133.3 of straight pipe. Then we will have .243' × 13.33 + .5' = 3.74' total head required.

If we had five elbows in a run of 100 feet of pipe, then our problem would be 100' of 4" pipe + 500 diameters (or 166.5') = 266.5'. Then .243' × 26.65 + .5' = 6.97 as the total head required for passing 50 U. S. gallons per minute. Of course when the elbows are better than the common, as explained under "Loss of Head by Elbows or Bends," then fewer diameters must be considered and added as the value of the elbows.

By the above simple means we can always determine the amount of head necessary to produce a certain result in pipes that have been already run. In other words, should we go into a building that had been already piped, or should we have the plans of a job before us, with the lengths and sizes marked, and wished to know if the diameters of the pipes were ample or not for a given velocity and quantity, we would proceed as above and determine the total head; when it would be manifest whether the pipes were greater or less than they should be.

(2.) To find the quantity of water that will pass in U. S. gallons when we know the total head at our disposal and the length and the diameter of our pipe.

This is one of the most important points to a designer of hot-water apparatus. Where the total head at our disposal is known we are at a loss to know how much of the head is required to overcome the friction and how much is left to produce motion in the water. This does not admit of a direct solution, but we can take advantage of the fact that the discharge by any pipe or series of pipes and fittings is proportional to the square root of their heads (and that conversely the head is proportional to the square of the discharge), and therefore all we have to do is to assume a discharge for our pipe, and after having found the head necessary for the assumed discharge (as in 1) apply the above rule thus:

Assumed discharge × by square root of required head ÷ by square root of assumed head.

Thus, say, we want to find the number of U. S. gallons that will pass through a 4-inch pipe 100 feet long under one inch of total head; we will commence by assum-

say, 50 gallons, and already by (1) we have found that 50 gallons required a total head of 2.95 inches of water, which we will take now as our assumed head; therefore we have quantity looked for —

$$50 \text{ gallons} \times \sqrt{1'} \\ \sqrt{2.95}$$

which is equalled by

$$\frac{50 \times 1}{1.70} = 29.4 \text{ U. S. gallons}$$

as the quantity that will pass under one inch of total head through a 4-inch pipe 100 feet long.*

Having now found the quantity of water that will pass through 100 feet of 4-inch pipe under a one-inch head, it is important, also, that we should be able to establish the diameter of a pipe of the same length and under the same head that will discharge some other desirable or fixed quantity of water.

First we found the total head for an assumed quantity, the length and diameter being known (1). Then we found the actual quantity that would pass through the same pipe under the smaller head of one inch (2), and now we want to establish a new diameter—the length remaining the same—that will pass, say, 50 gallons, as at first assumed (1), but to pass it with only one inch of head (2).

This can be done by taking advantage of the fact that the diameters of pipes vary directly as the fifth root of the square of their discharges, head and length remaining the same; in other words, the diameters of pipes are proportional to the $\sqrt[5]{\text{discharge}}$.

(3.) Thus our third problem is:

To find the diameter a pipe should be for a given discharge under equal heads with another pipe, whose length, diameter, and discharge is known.

In our last problem (2) we found that 29.4 U. S. gallons would pass through 100 feet of 4-inch straight pipe under a total head of one inch. Let us now see how large a pipe of the same length it will take to pass 50 U. S. gallons under one inch total head.

The sum, according to the rule given, resolves itself into a simple proportion thus:

The fifth root of the square of 29.4 gallons . . . a diameter . . . the fifth root of the square of 50 gallons . . . × inches
of 29.4 gallons . . . of 4 inches . . . of 50 gallons . . .

— the new diameter in inches. Or the following simple formula:

$$\frac{\sqrt[5]{\text{gallons. inches.}}}{50.0 \times 4} = 4.9 \text{ inches.}$$

the new diameter.

It probably is not plain to many practical men how this answer is obtained, so we will endeavor to go over it in a simpler manner.

When the discharges from pipes are in the ratios of 1, 2, 3, 4, 5, 6, etc., the diameters will be in the ratio of 1., 1.32, 1.55, 1.74, 1.90, 2.05, etc.

These ratios of the diameters may be picked out of Trautwine's tables of Fifth Roots and Fifth Powers by squaring the discharges and substituting the answers thus found for the "Power" in the tables; opposite to which is the Number or Root that is the ratio of the diameter.

In our case, then, we have 29.4 and 50 gallons respectively that we must first square and then find the fifth roots of the respective squares. To get the fifth root of the square of either of these numbers will take us far beyond the limit of the tables of reference cited heretofore, but we may (without much error) use some common divisor, such as 10, and reduce the discharges to 3 and 5 respectively and then proceed as above. Thus 3 squared = 9, the fifth root of which is 1.55. Then 5 squared = 25, the fifth root of which is 1.9.

Then 1.55 : 4 :: 1.9 : X'

$$\begin{array}{r} 1.9 \\ 1.55 \overline{) 7.60} \quad 4.9 \text{ inches.} \\ \underline{6.20} \\ 1.400 \\ \underline{1.395} \\ 5 \end{array}$$

*Those who do not wish to work out the square roots of numbers can find tables in Trautwine's or Haswell's Pocket-Books that give the desired information.

†As it is a difficult thing to extract the fifth root of a number, and as practical men rarely wish to go into abstract calculations, I will refer them to Trautwine's Engineering Pocket-Book, where they will find tables of fifth roots and fifth powers that will obviate tedious calculations and, presumably, avoid clerical errors.

Thus the diameter sought is very nearly five inches, and as there is no 4.9 merchantable pipe the nearest practical size larger (5-inch) should be used.

(4) To find the discharge by pipes of different diameter, the head and length being the same.

This is necessary for the engineer when he has found the capacity of one set of pipes and wishes to know the capacity of another set, either larger or smaller in diameter but with the same head and length.

The rule for this is, that the discharges from pipes of equal lengths and heads is in the ratio of the 2.5 power of the diameter or the converse of the foregoing (3). The symbol "2.5 power" means the square root of the fifth power of a number as here written.

For the reason given before to practical men, a table of the 2.5 powers of numbers can be used much more readily than to attempt to find the root and raise it to its fifth power, therefore I refer the reader to Trautwine's tables again in this matter and by a study of the same it will show that with diameters in the ratio of 1, 2, 3, 4, 5, 6, etc., the ratio of discharge will be 1., 5.65, 15.59, 32., 55.9, 88.18, and so on.

Let us, then, proceed to find the discharge by 100 feet of 6-inch pipe under a 1-inch head; the discharge by a 4-inch pipe of the same length and head being 29.4 gallons. This is simple proportion again, so long as we have the ratio the discharge bears to the diameter, and this can be taken from the tables of the "Square Root of Fifth Powers" before mentioned, or the above ratios may be used as far as they go. Thus:

2.5 power of known diameter : known discharge :: 2.5 power of required diameter : (X) discharge —
(in this case) 4" : 29.4 gallons :: 6" : (X). Then substituting the ratio for the diameters we have:

Ratio. Gallons. Ratio.
32 : 29.4 :: 80 : X

or nearly 73½ U. S. gallons that will pass through a 6-inch pipe 100 feet long under one inch of head.

(TO BE CONTINUED.)

ENGLISH PLUMBING PRACTICE.

BY A JOURNEYMAN PLUMBER.

(Conclusion of article LXVII. on page 380, September 3.)

HOT WATER FITTINGS (CONTINUED).

HOT-WATER cylinders are made of galvanized-iron plate varying from about .094 to .25 of an inch, or of sheet copper of about .035 to .120 of an inch in thickness. In some cases the copper cylinders are tinned inside.

The shape of the iron cylinders is generally as shown in sectional elevation Fig. 5. The sketch shows the posi-

FIG. 5

tion of the manholes and connecting bosses, and speaks for itself. The bottom is domed upwards, as shown, as being more convenient for riveting, and also because if a

flat bottom is put on the pressure of water is found to make the bottom bulge downwards, so that the cylinder will not stand firm on a flat shelf or platform. Copper cylinders are sometimes made with the bottom domed downwards, and, instead of being riveted up the seams, are brazed together. When made this way, and the cylinder is to stand upright, a hollowed seating or bracket must be made for the bottom to rest in.

Some copper cylinders have the straight seams dovetailed and brazed, and the domical ends soft-soldered on, but as after a time the soldering comes away from the copper it is necessary to solder, or sweat, as it is sometimes called, an outer ring of copper over the soldered seam as an extra precaution against a leakage or breaking asunder of the domes and the body of the cylinder.

Figure 6 is an elevation showing the copper cylinder as described, and with a piece broken out so as to show the section of the joints referred to.

FIG. 6

The round cylinders are generally made with bridged manholes, as described for the boilers, for access to the inside for cleansing, etc.

Cylinders, as a rule, should stand above the level of the boiler, and should not be fixed on wooden shelves or brackets, but should have iron stands or brackets. Brick bases are sometimes built to support the cylinders, but the brackets are best, as more room is left for access for making the connections or giving any attention to them that may be necessary.

No. LXVIII.

CYLINDERS AND HOT-WATER CIRCULATION.

HOT-WATER cylinders should always be inclosed so as to avoid unnecessary waste of heat by radiation. They may be fixed in an inclosed recess, or covered with a non-conducting material such as "fossil meal," and other similar preparations.

A wooden casing may be fitted round them, with a space left between to be afterwards filled with a suitable material.

Dry hair-felt has been much used for this purpose, but the writer has recently had to take away all the felt that

For ordinary use "slag-wool" has been found very efficient to prevent radiation of heat from cylinders and is free from the objections referred to above, but it is necessary to have an outside covering. As the cylinder is usually fixed in the kitchen, anything unsightly should be avoided. For first-class work nothing looks smarter than a polished mahogany lagging, with bright polished brass bands or hoops to hold it together, and if the hoops are tightened up with screws the whole inclosure can easily be taken to pieces, should it be necessary to do anything to the cylinder or the connections.

I think I have read somewhere in THE SANITARY ENGINEER AND CONSTRUCTION RECORD that in New York it is the practice to supply the hot-water system direct from the public water-main. This must be a very dangerous practice. Although the writer has no experience of this kind, still he cannot help thinking that there is danger of the boiler bursting, besides the annoyance of being without hot water should the mains break down or be emptied for repairs to them or any branch connections; or the pressure from the mains would be seriously reduced should all the water be required to supply the engines when a fire broke out in the neighborhood. In the writer's practice he always advises that the water be laid on from the main to a cistern or cisterns, which will hold at least enough for twelve hours' consumption.

We will now return to the question of hot-water circulation.

The pipes between the boiler and cylinder should never be less than 1¼-inch in diameter, but 1½-inch is much better. Or, if smaller pipes are used, the connections themselves to the boiler should be of the sizes stated, as it is not at all uncommon to find the ends in the boiler partly filled with fur, and especially where very hard waters are used. The cylinder may be fixed in any convenient position, but it is usual and best to fix it as near the boiler as possible.

Figure 1 represents a very good way for connecting the pipes, and a great many men fix them so.

Figure 2 is another way much practiced. In this figure the cold-water service-pipe is connected with the return-pipe to the boiler, for the reason that it has been thought not advisable for cold water to enter the boiler to replace the hot water that has passed away into the system of pipes. By connecting it with the return-pipe a certain quantity of warm water from the cylinder mixes with the cold, thus not submitting the iron boiler to sudden expansions and contractions. In Fig. 1 the cold water is shown as passing directly into the boiler. In Fig. 1 the manhole is shown as usually fixed, and in Fig. 2 it is shown near the bottom of the cylinder, so that any mud or sediment can be more easily removed. In Fig. 2 the pipes from the cylinder are shown as running horizontally. It is

was placed round some hot-water pipes, as moths were found to propagate in that material. In the case referred to the moths propagated to an extent that would appear almost incredible, and then spread into the woolen furniture of a house and had played sad havoc, some being almost entirely ruined and spoilt. In another case fleas were found to an unpleasant extent, and the hair-felt had to be removed because it was found to harbor them.

found in practice that the water will not circulate so freely in horizontal as in vertical pipes. In cases similar to the one quoted it has been found necessary to fix the pipe N from the boiler flow to the cylinder flow-pipe, so as to accelerate the circulation in the cylinder-pipes. It may here be mentioned that no draw-off cocks should be fixed or connected to the boiler or cylinder, but should be branched into the flow-pipe from the cylinder. The

reason for this is, that should the cold-water supply be exhausted or cut off for any purpose, it would not be possible to empty the boiler, etc., for reasons it is not necessary to repeat. A special cock should be fixed for the plumber to empty the cylinder when necessary for cleaning out or making any repairs. This cock should have a square head, or else be locked up so that servants could not tamper with it or make use of it. This cock is shown at O, Fig. 2. In some instances a pipe is connected with this cock so as to discharge the contents of the cylinder into a drain or waste-pipe. This is not a good plan, as the cock may be left open so that the water can run to waste and not be noticed. It is much better to fix a bibb cock as shown, so that the water can be drawn into pails. This gives a little more trouble to the plumber, but as it has to be done only once or twice in a year, the trouble is not worth considering. A stop-cock should always be fixed in the cold-supply-pipe as shown at P, Fig. 2, so that in case of accident the water can be shut off at once instead of the person in charge having to run to the top of the house, or wherever the cold tank is fixed, to shut off the supply. No expansion-pipe is shown in the figures, as it is usual to fix that from the highest point of the circulating-pipes.

The circulating-pipes from the cylinder should never be less than 1-inch diameter; $1\frac{1}{4}$ -inch is better, and for large mansions the writer has used $1\frac{1}{2}$ -inch pipes. In addition to iron, galvanized iron and copper pipes, as described in an earlier paper, lead, and lead-encased tin pipes have been used for hot-water pipes. Lead pipes have now fallen into disuse; indeed, the writer has not fixed any lead circulation-pipes for this last fourteen years. Hot and cold water passing alternately through lead pipes causes them to expand and contract to such an extent as to cause the pipes to break, and this occurs more when the pipes are too firmly fixed. Branch pipes frequently break near the joint to the main pipes. On looking closely at the ends of the fractured pipes the lead looks as if its particles were disintegrated, and there is no doubt that it is the want of tenacity in the metal that will not bear a tensile strain when shrinking that is the cause of the pipe being pulled asunder. The writer has used lead-encased tin pipe for hot-water work, and will not readily forget his first job. The great difficulty was to make the joints. A plumber's wiped-joint was found to melt the inside lining of tin, leaving a thin shell of lead, the tin melting and running into a mass in the bottom of the inside of the joint. Blow-pipe and copper bit-joints were tried and found to be failures. Next was tried a lining of pasted brown paper inside the joints. This answered fairly well, but the paper was found to wash off, and several pieces would congregate in some bend or branch-joint and cause a stoppage. The ends of the pipe were packed with whiting, but that was not a success. Tinned sheet-iron nipples inside the pipe ends were fairly successful, but it was found that gun-metal coupling-unions were the best means for connecting the pipes.

Figure 3 is a section of a joint made as described. The pipe ends were passed through gun-metal linings and tafted or flanged over. These linings had hexagonal ends at R R, and spanners were used for screwing them into the socket S. T is an asbestos or Indian-rubber washer, but if the flanged ends of the pipe are properly done and left with a smooth face, they can be butted together and screwed up so as to be water-tight without any washers. These joints require periodical examination and further screwing up, especially when the pipes are in long straight lengths. Horizontal pipes should always lie on wooden fillets fixed to the wall. If fixed on hooks the pipe will bag down between the fixings. The wooden fillet should be rather wide. Although it does not add to the appearance of the work, it is best not to have the pipes too straight so that they will have a direct strain on the screwed coupling connections, but any bends in horizontal pipes must lay flat on the fillet, or air will accumulate in any high parts. When pipes are quite straight the joints leak by the alternate pull and thrust motion which is continually taking place at each change of temperature of the water inside them. It is often lost sight of, but a fact nevertheless, that hot-water pipes when in use are *always in motion* and cannot be said to be still for more than a few seconds at a time.

Great care should be taken when making branch connections for draw-off pipes. Figure 4 is a section showing the T-union used for a branch pipe. It is a good plan not to have the branch pipe quite straight, but to bend it as shown, so as to allow for a slight motion of both the main and branch pipes, and thus render the liability of a

strain on the joint to a minimum. In some cases the writer has fixed the branch joint upwards as shown at Fig. 5, so as to allow for the motion predescribed.

Figure 6 is a bird's-eye view of a cylinder and the circulating pipes fixed to a nobleman's mansion in the country (England). The whole of the pipes were lead-encased tin. U U were draw offs to sinks on the ground floor. V V were similar draw-offs on the first or chamber floor. W W were baths. X X were wash-hand basins, and Y was the expansion-pipe. This was placed at the highest point of the circulating-pipe. Doorways and similar obstacles compelled this to be fixed where shown. The return-pipe was taken back and branched into the cylinder as shown at Z. This no doubt caused a slight check on the circulation of the water, but it was deemed advisable to make the connection as shown. It was thought that by reason of the long length of pipe and the consequent friction of the water passing through that any water drawn at the cocks U' U' would most likely be cold instead of hot if it had been connected in the usual way.

(TO BE CONTINUED.)

Novelties.

Under this heading we propose to describe and illustrate appliances of probable interest to our several classes of readers. The selection will be made without reference to the wishes of agents or patentees, being governed solely by considerations of novelty, ingenuity, and probable interest to readers, and especially the fact that they have not been elsewhere described. As a rule we shall make no comments, and it is to be distinctly understood that a notice does not imply approval. No charge will be made for these notices, and any offer of pay for their insertion will insure their omission. We shall be glad to have our attention called to novelties suitable for this section.

SWINGING CHECK-VALVE.

THE accompanying cuts show a novel swinging check-valve lately patented by James P. Neary, of Bridgeport, Conn. It has for its object to provide a device that will give an absolutely straight waterway that is withal simple

in construction and arrangement, and which shall seat automatically and tightly, irrespective of any wear which may occur either to the packing of the disk or to the seat, and consists in a valve casing and seat, which projects within the casing in the direction of the flow, and having a swinging disk suspended between the arms of a swinging yoke, with a projecting prong on the top of the disk, which engages with a similar projection within the cap or "nut" of the valve, when the valve or disk is forced from its seat by the passage of the water turning the disk and holding it in the plane of the current.

GRIP FOR CABLES.

THIS device is an improved form of grip for tightening derrick cables or guys. Figure 1 is perspective view, with the parts represented in full lines as they appear when in position to grip the cable, the dotted lines indicating position of lever-arm *b* when sliding jaw *d* is released from the cable.

The parts indicated by *a*, *c*, and *e* are made of a solid piece of wrought iron. Figure 2 shows a slot in head-plate *c* in which the movable jaw *d* slides freely. The lever-arm *b* has a curved face, and therefore will force jaw *d* to grip the cable in proportion to power applied.

To use this device a cable is inserted in the jaws *d e*, and hook of guide-arm *a* placed over cable. The tackle or other power is then applied to lever arm *b* and drawn taut, which will force the movable jaw *d* to grip the cable. If proper tension has not been imparted to the

cable on first trial it can be made fast, the grip released, and moved along the cable in the direction of the arrow to a new position, when the operation can be repeated.

This device was invented by Patrick Kelly, of Poughkeepsie, and is made by John Claffy, 48 Dey Street, New York.

Correspondence.

All correspondents should send us their names and addresses, not necessarily for publication, but as a guarantee of good faith and because it is often necessary to communicate with them for additional information before printing their communications. Anonymous letters will not be noticed.

A MAN TO PUT DOWN IRON SCREW-PILES.

IN response for request for a good man to put down "iron screw-piles," we have received the following:

Union Bridge Company recommend J. W. Hoes, Columbia County, N. Y., as having done a good job of that character for them in South America.

T. P. Kingsley, of Amherst, Mass., had charge of such work at Coney Island, N. Y.

Cofrode & Evans, of Pottstown, Pa., suggest D. R. S. Cofrode, 31 Montgomery Street, Jersey City; Robert Gibson, 331 Walnut Street, Philadelphia.

SWITCH-VALVE MANUFACTURERS.

BALTIMORE, September 12, 1887.

SIR: In response to the inquiry of "Switch-Valves" in your issue of the 10th inst., you can refer your inquirer to us, as we are the manufacturers of these articles.

BARTLETT, HAYWARD & Co.

CELLAR FLOODING FROM SUB-SOIL DRAINS IN SAME TRENCH WITH PIPE-SEWERS.

NEW YORK, September 7, 1887.

SIR: Some instances have come to my notice of cellar-flooding on line of small pipe-sewer, where sub-soil drains were laid in the same trench to carry off ground-water with sub-soil pipe laterals connecting with cellar-drains. It is supposed that during heavy rains the sub-soil pipes reversed their intended action, and becoming surcharged and under pressure, found relief by backing up through the laterals, flooding the cellars. Do you know of any similar instances at Memphis, Norfolk, or elsewhere?

Yours truly, W.

[We should be glad to hear from our readers in these cities.]

WESTERN ASSOCIATION OF ARCHITECTS.

LA FAYETTE, IND., September 10, 1887.

GENTLEMEN: At the last annual convention of the Western Association of Architects Article 10 was added to the by-laws, which reads as follows:

Article 10, By-Laws.—"All names of candidates are to be presented to the Board of Directors, and by them sent

to all members of the association thirty days before the meeting of the convention."

The requirements of article 10 are imperative—that all applications for membership must be filed with the Secretary on or before October 15, 1887. Members of all committees are earnestly requested by the Board of Directors to file their final report with the Secretary on or before October 15, 1887.

The last called meeting of the Board of Directors for the transaction of general business preceding the November convention will be held in Chicago October 18, 1887.

JAMES F. ALEXANDER,
Secretary Western Association of Architects.

BOOKS ON SCHOOL ARCHITECTURE WANTED.

LINDSAY, ONT., September 8, 1887.

SIR: Can you obtain for me a book entitled, "United States Work on School Architecture," or where it is published, and the price?

Also the same question as to report on "City Schools in the United States," by Dr. J. D. Philbrick.

Both the above works are quoted by our "Educational Department," and I should like to get them. If you can kindly give me the information asked for above, you will greatly oblige your subscriber to THE SANITARY ENGINEER AND CONSTRUCTION RECORD. WM. DUFFUS,

Lindsay, Ont., Box 407.

[Referred to our readers.]

HAVE STREET-SCRAPINGS BEEN PROFITABLY EMPLOYED AS A FERTILIZER?

NEW HAVEN, CONN., September 5, 1887.

SIR: In THE SANITARY ENGINEER AND CONSTRUCTION RECORD of May 14 last, page 633, you advise that "ordinary street-scrappings * * * should be used for fertilizing," etc.

I hoped to see some response to this, but seeing none, I write to ask that you collect and publish information on this point.

This seems the natural use to put street-scrappings to, but what success has attended such use?

For some years I have been on the lookout for cases where street-scrappings have been proved to have any agricultural value as a manure, and thus far I do not find any such cases where the stuff has practically any value.

I have heard, in a general and indifferent way, of places where they have been so used, where once on the ground they were disposed of harmlessly and perhaps did some good, but not enough to pay for the carting, or for any other material expense to get them on the land.

Several persons have told me of their experience in the attempted use of the street-scrappings of this city (New Haven, Conn.), and not one has told me that he has found them of any manurial value—that is, enough to pay for any trouble in getting them. On the other hand, several have claimed that the scrappings from our Telford pavements have proved actually injurious when applied to grass.

Here, as elsewhere, it is a problem what to do with the stuff. Our street-scrappings are too foul to be used for filling (although so used), and too clean to be of value for manure. I would like to know what the experience of other places has been. Yours respectfully,

WILLIAM H. BREWER.

[We shall be glad to publish the experience of any of our readers with the problem referred to by Professor Brewer. Our own does not enable us to recall any instance where it has been found profitable to use street-scrappings as a fertilizer.—ED.]

THE CENTENARY OF STEAM.

(From the New York Times.)

An American Inventor Unhonored at Home—Oliver Evans, who Patented, Built, and Worked the First High-Pressure Steam-Engine.

To the Editor of the New York Times:

OF all the inventions of ancient or modern times none have more importantly and beneficently influenced the affairs of mankind than the double-acting high-pressure steam-engine, the locomotive, the steam-railway system, and the steamboat, all of which inventions are of American origin. The first three are directly and the last indirectly associated with a patent that was granted by the State of Maryland in 1787, being the very year of the framing of the Constitution of the United States. In view of the momentous nature of the services which these four inventions have rendered to the material and national interests of the people of the United States it is to be hoped that neither they nor their origin will be forgotten in the coming celebration of the centennial of the framing of the Constitution.

The high-pressure steam-engine in its stationary form is almost ubiquitous in America. In all great iron and steel works, in all factories, in all plants for lighting cities with electricity—in brief, wherever in the United States great power in compact form is wanted, there will be found the high-pressure steam-engine furnishing all the power that is required, and more, too, if more is demanded, because it appears to be equal to every human requisition. But go beyond America. Go to Great Britain, and the American steam-engine—although it is not termed American in Great Britain—will be found fast superseding the

English engine—in other words, James Watt's condensing engine. It is the same the world over. On all the earth there is not a steam-locomotive that could turn a wheel but for the fact that, in common with every locomotive from the earliest introduction of that invention, it is simply the American steam-engine put on wheels, and it was first put on wheels by its American inventor, Oliver Evans, being the same Oliver Evans to whom the State of Maryland granted the before-mentioned patent of 1787.

He is the same Oliver Evans whom Elijah Galloway, the British writer on the steam-engine, compared with James Watt as to the authorship of the locomotive, or rather "steam-carriage," as the locomotive was in those days termed. After showing the unfitness of Mr. Watt's low-pressure steam-engine for locomotive purposes, Mr. Galloway, more than fifty years ago, wrote: "We have made these remarks in this place in order to set at rest the title of Mr. Watt to the invention of steam-carriages. And, taking for our rule that the party who first attempted them in practice by mechanical arrangements of his own is entitled to the reputation of being their inventor, Mr. Oliver Evans, of America, appears to us to be the person to whom that honor is due." He is the same Oliver Evans whom the *Mechanics' Magazine* of London, the leading journal of its kind at that period, had in mind when, in its number of September, 1830, it published the official report of the competitive trial between the steam-carriages Rocket, San Paniel, Novelty, and others on the Liverpool and Manchester Railway. In that trial the company's engines developed about fifteen miles in an hour and spurts of still higher speed. The *Magazine* points to the results of the trial and then, under the heading of "The First Projector of Steam-Traveling," it declares that all that had been accomplished had been anticipated and its feasibility practically exemplified over a quarter of a century before by Oliver Evans, an American citizen. The *Magazine* showed that many years before the trial Mr. Evans had offered to furnish steam-carriages that, on level railways, should run at the rate of 300 miles in a day, or he would not ask pay therefor. The writer will state that this offer by Mr. Evans was made in November, 1812, at which date not a British steam-carriage had yet accomplished seven miles in an hour.

In 1809 Mr. Evans endeavored to establish a steam railway both for freight and passenger traffic between New York and Philadelphia, offering to invest \$500 per mile in the enterprise. At the date of his effort there was not a railway in the world over ten miles long, nor does there appear to have been another human being who up to that date had entertained even the thought of a steam-railway for passenger and freight traffic. In view of all this, is it at all surprising that the British *Mechanics' Magazine* declared Oliver Evans, an American, to be the first projector of steam-railway traveling? In 1804 Mr. Evans made a most noteworthy demonstration, his object being to practically exemplify that locomotion could be imparted by his high-pressure steam-engine to both carriages and boats, and the reader will see that the date of the demonstration was three years before Fulton moved a boat by means of Watt's low-pressure steam-engine. The machine used involved the original double-acting high-pressure steam-engine, the original steam-locomotive, and the original high-pressure steamboat. The whole mass weighed over twenty tons. Notwithstanding there was no railway, except a temporary one laid over a slough in the path, Mr. Evans's engine moved this great weight with ease from the south-east corner of Ninth and Market Streets, in the city of Philadelphia, 1 1/4 miles to the River Schuylkill. There the machine was launched into the river, and the land-wheels being taken off and a paddle-wheel attached to the stern and connected with the engine, the now steamboat sped away down the river until it emptied into the Delaware, whence it turned upward until it reached Philadelphia. Although this strange craft was square both at bow and stern it nevertheless passed all the up-bound ships and other sailing vessels in the river, the wind being to them ahead. The writer repeats that this thorough demonstration by Oliver Evans of the possibility of navigation by steam was made three years before Fulton. But for more than a quarter of a century prior to this demonstration Mr. Evans had time and again asserted that vessels could be thus navigated. He did not contend with John Fitch, but, on the contrary, tried to aid him, and advised him to use other means than oars to propel his boat. But Mr. Fitch was wedded to his own methods. In 1805 Mr. Evans published a book on the steam-engine, mainly devoted to his form thereof. In this book he gives directions how to propel boats by means of his engine against the current of the Mississippi. Prior to this publication he associated himself with some citizens of Kentucky—one of whom was the grandfather of the present General Chauncey McKeever, United States Army—the purpose being to build a steamboat to run on the Mississippi. The boat was actually built in Kentucky and floated to New Orleans. The engine was actually built in Philadelphia by Mr. Evans and sent to New Orleans, but before the engine arrived out the boat was destroyed by fire or hurricane. The engine was then put to sawing timber, and it operated so successfully that Mr. Stackhouse, the engineer who went out with it, reported on his return from the South that for the 13 months prior to his leaving the engine had been constantly at work, not having lost a single day.

The reader can thus see the high stage of efficiency which Oliver Evans had imparted to his engine full 80 years ago. On this point Dr. Ernst Alban, the German writer on the steam-engine, when speaking of the high-

pressure steam-engine, writes: "Indeed, to such perfection did he (Evans) bring it, that Trevithick and Vivian, who came after him, followed but clumsily in his wake, and do not deserve the title of either inventors or improvers of the high-pressure engine which the English are so anxious to award to them. * * * When it is considered under what unfavorable circumstances Oliver Evans worked his merit must be much enhanced; and all attempts made to lessen his fame only show that he is neither understood nor equalled by his detractors."

The writer has already shown that there are bright exceptions to this general charge brought by Dr. Alban against British writers, but the overwhelming mass of them have acted more like envious children than like men when speaking of the authorship of the double-acting high-pressure steam-engine, the locomotive, and the steam-railway system. Speaking of this class of British writers, Professor Renwick, when alluding to their treatment of Oliver Evans, writes: "Conflicting national pride comes in aid of individual jealousy, and the writers of one nation often claim for their own vain and efficient projectors the honors due to the successful enterprise of a foreigner." Many of these writers totally ignore the very existence of Oliver Evans, and all of them attribute to Trevithick and Vivian the authorship of the high-pressure steam-engine and the locomotive. Yet, when doing so, all of them substantially acknowledge the American origin of both inventions, because it is morally certain that Trevithick and Vivian got possession of the plans and specifications of his engine. Oliver Evans sent them to England in 1794-5 by Mr. Joseph Stacy Sampson, of Boston, with the hope that some British engineer would approve and conjointly with him take out patents for the inventions. Mr. Sampson died in England, but not until he had extensively exhibited Mr. Evans's plans, apparently, however, without success. After Mr. Sampson's death Trevithick and Vivian took out a patent for a high-pressure steam-engine. This could happen and yet the invention be original with them. But they introduced into Cornwall a form of boiler hitherto unknown in Great Britain—namely, the cylindrical flue boiler—which Oliver Evans had invented and used in America years before the names of Trevithick and Vivian were associated with the steam-engine. Hence, they were charged over 50 years ago with having stolen the invention of Mr. Evans, and the charge has never been refuted. Hence, when British writers ignore the just claims of Oliver Evans, and assert for Trevithick and Vivian the authorship of the high-pressure steam-engine and the locomotive, they thereby substantially acknowledge the American origin of both inventions. They are not only of American origin, but their author, although born in 1755, was, nevertheless, an American of the second generation, seeing that he was descended from the Rev. Dr. Evans Evans, who in the early days of the colony of Pennsylvania came out to take charge of the Episcopal Church in Pennsylvania.

The writer has thus shown that with the patent granted by the State of Maryland to Oliver Evans in 1787 were associated, first, the double-acting high-pressure steam-engine, which to-day is the standard steam-engine of the world; second, the locomotive, that is in world-wide use; third, the steam-railway system which pervades the world; fourth, the high-pressure steamboat, which term embraces all the great ocean steamships that are actuated by the compound steam-engine, as well as all the steamships on the Mississippi and its branches.

The time and opportunity has now arrived to assert before all the world, gathered at the coming celebration of the centennial of the Constitution, the American origin of these universally beneficent inventions. Such a demonstration should be made, if only for the instruction of the rising generation. Not a school-book has fallen into the hands of the writer that correctly sets forth the origin of the subject-matter of this paper. He apprehends that it is the same with the books used in colleges and universities, for otherwise how could that parody on the history of the locomotive, called "The Life of George Stephenson, Railway Engineer," by Samuel Smiles, have met such unbounded success? To the amazement of the writer, a learned professor in one of the most important institutions of learning in the country did, in a lecture, quote Smiles as authority on a point bearing on the history of the locomotive! It is true that he made amends by adding, when his lecture was published, a counter-statement; but that such a man should have seriously cited such a work shows the widespread mischief done among people not versed in engineering lore by the admirably written romance of Smiles, who, as Edward C. Knight in his *Mechanical Dictionary* truly declares, has "pettifogged the whole case." If, as Professor Renwick intimates, "conflicting national pride" has led the major part of British writers to suppress the truth as to the origin of the high-pressure steam-engine, the locomotive, and the steam-railway system, surely true national pride should induce the countrymen of Oliver Evans to assert it. In closing this paper, the writer will say, for the information of the so-called "practical" men of the country, or, in other words, those men whose judgment of an invention is mainly guided by its money value, that Poor's Manual of Railroads in the United States for 1886 puts their capital stock and their debts at over \$8,162,000,000. The value of the steamships and steamboats actuated by the high-pressure steam-engine the writer has no means of ascertaining. Neither can he appraise the factories and other plants in the United States—to say nothing of the rest of the world—in which the high-pressure steam-engine forms the motive power.

AN AMERICAN CITIZEN.

Gas and Electricity.

Illuminating Power of Gas in New York City.

Week ending	New York Gas-Light Company.	Manhattan Gas-Light Company.	Metropolitan Gas-Light Company.	Mutual Gas-Light Company.	Municipal Gas-Light Company.	Krickerbocker Gas-Light Company.	Equitable Gas-Light Company.
September 10.....	23.95	22.04	22.91	28.42	27.41	23.89	29.85

E. G. LOVE, Ph.D., Gas Examiner.

THE *Progressive Age* illustrates several forms of the Lowe incandescent gas-light. These consist of a filament, in the shape of a horse-shoe, suspended over an ordinary flat-flame burner. To the inner side of this filament is attached what appears to be a many-fluted wire. The material composing these burners is stated to be "four or five of the rare indestructible metals." The smallest size burner is said to give a ten-candle light, while the larger size will give a twenty-candle light, "by the use of no other agent than plain fuel, water-gas," etc. Our contemporary says that two years' practice has shown that there is no deterioration in the metal itself, and if a filament should become injured it can be exchanged at a cost of five cents.

THE Electrical Exhibition of the American Institute will be held in this city from September 28 to December 3. The exhibits will be divided into six sections as follows: (1) Production of Electricity; (2) Apparatus Requiring Powerful Currents; (3) Apparatus Requiring Comparatively Weak Currents; (4) Electric Conductors; (5) Electrical Measuring Apparatus; (6) Historical and Miscellaneous Exhibits.

THE *Electrician* gives the following account of the arrangements which have been made by the British and Continental Gas Association for lighting the Vienna Opera-House by electricity: The dynamos are of the Crompton vertical type, with double horse-shoe magnets, and give an output of 120 amperes at 600 volts. They are employed to charge in series five sets of batteries which discharge over independent circuits. The lighting of the stage is controlled by a special switch connected with both arc and incandescent lamps inclosed in globes of various colors, and the combinations are so arranged as to give the effects of daylight, dawn, sunset, the furious blaze of a conflagration, or pale silvery moonlight. It is anticipated that these effects will surpass anything of the kind hitherto attempted. To avoid any unnecessary disturbance of the walls, which are very handsomely decorated, it was found possible to make use, to a considerable extent, of the gas-pipes as channels for the wiring.

THE following points of interest to electricians are taken from the *Gastekniker's* report on the lecture by Fr. Ross before the Austrian Elektro-technischen Verein on "Electric-Light and Power Plants in the United States." There are 426 central stations in the United States for electric-lighting, a few of which furnish power. They supply 80,000 arc, and 300,000 incandescent lights. To do this they expend 150,000 horse-power. The numerous lights run from isolated plants are not included in the above. Water-power is seldom used. The length of wires necessary is 550 kilometres on poles, and about 50 kilometres underground. Towers are very generally used for city lighting, and with great success. These towers range from 38 to 76 feet in height, and stand 240 to 850 feet apart. Mr. Ross speaks specially of Detroit, where he says they would require 12,000 gas-lamps to light the surface now illuminated by 122 towers, this surface being double that of Vienna. There are about 100 kilometres of electric railroads in this country. Electric motive power furnished from stations is very much cheaper here than in Europe.

Mr. W. J. DIBDIN has presented to the Metropolitan Board of Works (London), the results of his elaborate tests of various photometric standards. The work included 2,120 tests, or over 20,000 observations. Speaking of the proposed standards, Mr. Dibdin says:

"In selecting a substitute for the present legal candle, care should be exercised to insure that it complies with the three main conditions which apply to the present standard—viz.: 1. That it should have a definite combustible material. 2. That the condition in which that com-

bustible material exists at the time of use should be under control and capable of inspection for verification. 3. That the rate of combustion, and the manner in which it is effected, should be readily and accurately observed. By applying these considerations to each of the proposed standards, a guide is at once obtained for the selection of the most suitable. The pentane air-gas, as devised by Mr. A. Vernon Harcourt, the Keates lamp, and the amyl-acetate flame of Herr von Hefner-Altenneck, all answer to the requirements of these conditions; while the Methven screen, the pentane lamp, the ten-candle test, and its improved form, which I have called the 'Pentane Argand,' although each giving most excellent results in practice, fail to comply with these requirements, as they each depend upon a purely arbitrary rate of consumption of combustible material, coupled with a definite height of flame, but no check is afforded by means of which an involuntary error in the setting of the flame by the observer can be afterwards detected. Of those proposals answering to the above conditions, the Keates sperm-oil lamp has one serious defect—in that the wick, when once used, cannot be reignited without fresh adjustment or renewing, and thus a discrepancy is apt to occur. Furthermore, the practical difficulty found by various operators in obtaining a flame of uniform character seems to have been more serious than I had hitherto been led to suspect; and to such an extent has this been experienced that I am compelled to put it on one side in face of the more easily managed pentane air-gas and other proposed substitutes for candles. The amyl-acetate lamp has many points which entitle it to very careful consideration, not the least among these being its extreme simplicity and portability. It is, in fact, only a carefully constructed spirit-lamp; and in actual work has given most admirable results. Unfortunately, however, the color of the flame is its one weak point; and for this reason I am of opinion that it is not the most suitable for adoption as the standard. On the other hand, I have found the pentane air-gas to comply with every demand made upon it, and to answer to the full all the claims made for it by the inventor."

The "Pentane Argand" mentioned above consists of the Sugg 10-candle test supplied with pentane air-gas. In conclusion the report recommends that the "committee do advise the board to forthwith take such action as may be necessary to secure the adoption, with as little delay as possible, of the pentane air-gas standard as devised by Mr. A. G. Vernon Harcourt, F. R. S., etc., as the legal standard of light in this country. As, however, many practical photometrists are of opinion that a standard of light of more than one candle is desirable for many purposes, I further recommend that when the legal substitution of the pentane unit for the present candle be made, the Board of Trade should be empowered to sanction and authorize the use of such other standards and substitutes as that board may deem fit and proper to be used in place of and after comparison with the pentane air-gas flame."

A LARGE SYPHON.

A SYPHON of considerable interest has recently been constructed at the Fritzer Works, near Saurvik, in Norway. These works include a number of mills run by water-power from Farris Lake, the water being retained by a dam built 120 years ago. The height of fall utilized is 36 feet, and the supply of water required is 550 cubic feet per second. This supply could not be obtained through the sluices when the water sunk below a certain level, and it was determined to draw the water from a greater depth. The sluices could not be lowered, and the use of two siphons was therefore decided on which should draw water from four feet below the bottom of the sluices. These siphons are 82 feet long, and 5 feet 2 inches in diameter, and are made of riveted $\frac{1}{4}$ -inch steel plates. They have a suction height of 3 feet 11 inches, and are opened and closed by a ring sluice worked by one man. The air-pump acts on both siphons, and four men can pump the air out of them in ten minutes. The mouth-pieces are of cast-iron, and rest in 12-inch timbers covered with 3-inch boarding. The cost of the siphons was 40,000 kroner, and they are giving great satisfaction.—*Engineering*.

SEWAGE PURIFICATION AT ACTON.

THE sewage-works at Acton, near London, were opened the other day. The sewage from the high-level district runs into the water by gravitation; that from the low-level is pumped by two 35-horse-power engines into the channel leading to the tanks, where it is mixed with chemicals and then run into tanks to allow all solid matter to settle. The purification is effected by a combined process of precipitation and filtration, a special feature being the absence of lime in the ingredients used for this purpose. The material used for precipitation is the magnetic ferrous carbon and compound sewage salts supplied by the International Purification Company. After precipitation in the tanks, the surface liquid is passed through a filter-bed composed of granulated magnetic spongy carbon and sand; the purified effluent passes by a culvert

into the River Thames, a quarter of a mile distant. The sludge left at the bottom of the precipitation-tanks is then pumped up and forced through Drake & Muirhead's sludge-presses; the solid cake which is thus formed is then ground up for manure. It is claimed for this process that ninety per cent of the soluble organic matter is removed from the sewage, and that the effluent has not the deleterious effect upon a river of an effluent from a lime process.

A USEFUL MAN IN A CITY ENGINEER'S OFFICE.

(From the *Milwaukee Evening Wisconsin*.)

ALMOST everybody has a plan for abating the river nuisance, but it is not everybody that attempts to turn his plan to personal account. One such case, which occurred the other day, deserves recording. A man entered City Engineer Benzenberg's office and informed that official that he had a cheap plan for getting rid of the foul river-water. Encouraged to unfold his plan, he proceeded with the air of a man who is doing another a great favor to tell Mr. Benzenberg to "dig a few artesian wells above the dam and turn their flow into the river."

"How many do you think it would take?" asked the engineer, somewhat doubtful of the efficacy of the scheme.

"Not many. An ordinary well flows 24,000,000 gallons a day, and I should think four or five would do."

"The biggest well in this country," replied the engineer, "flows only 300,000 gallons a day, and it would take over a thousand of them to do the work."

"But they don't cost much," said the man, not to be downed.

"How much?"

"Perhaps \$2,000."

"Well, granted that one costs only \$2,000, and I think you would find its cost to be twice that amount, your project would cost \$2,000,000."

That staggered him, and he seemed greatly disappointed at the way his scheme had flattened out. He scratched his head thoughtfully for a moment and then said: "It don't look so cheap as it did, does it? But, say, can't you work me in a for a job somewhere around your department?"

BREAK IN RESERVOIR WALL AT ATLANTA.

A SMALL reservoir at Atlanta, Geo., comprising a portion of the system of water-works, broke away September 3 soon after having been filled with water. It occurred in that portion of the retaining-wall where the embankment had not been completed. The brick retaining-wall was intended to have ample strength to resist the pressure without the embankment. We are told a careful examination of the bricks has revealed a slight oily surface, which has been found to be due to the use of petroleum in the molds in manufacturing the bricks. It is claimed that this prevented a proper bond.

A PROPOSED ENGINEERS' CLUB IN NEW YORK.

A MOVEMENT has been inaugurated looking to the practicability of starting a social club for engineers, with a view to bringing the members of the several branches of the engineering profession into closer personal relations and afford a convenient headquarters for non-resident engineers during their visits to this city. It is proposed to call a meeting for organization as soon "as 250 eligible gentlemen in good standing as members of representative engineering societies have signified their willingness to join."

THE municipal authorities of Berlin have issued a series of instructions for the better protection of public buildings from lightning. The earth circuit from the rods must be copper cable not less than $\frac{1}{4}$ -inch diameter. Each rod must have a testing circuit and switch, insulated from the building and from earth and coming close to the ground, to obviate the need of climbing to the roof for testing purposes.

It frequently causes much trouble, indeed, in some cases, defies all efforts to free iron from ingrained rust, but, according to a German paper, the thorough cleansing of it may easily be effected by immersing the article in a nearly saturated solution of chloride of tin, even if much eaten into. The duration of the immersion will depend upon the thicker or thinner film of rust; in most cases, however, twelve to twenty-four hours will suffice. The solution of chloride of tin must not contain too great an excess of acid, otherwise it will attack the iron itself. After the articles have been removed from the bath, they should be first washed in water, and then with ammonia, and be dried as quickly as possible. Articles treated in this manner assume the appearance of dead silver.—*The Engineer*.

PERSONAL.

JOHN HENRY STEPHENS, architect, died at Closter, N. J., September 8, aged fifty-six years.

MR. WILLIAM N. CRAIGHILL, father of Colonel William P. Craighill, U. S. A., died last week in Charlestown, W. Va., in his eightieth year.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITIONS.

THE EIGHTY-EIGHTH REGIMENT P. V. ASSOCIATION invites plans and proposals until October 6, for the erection of a monument on the Gettysburg Battlefield. Louis Wagner, Chairman, 419 Walnut Street, Philadelphia.

MADISON SQUARE GARDEN COMPETITION.—The Building Committee, on advice of Professor W. R. Ware, professional adviser of new building competition, have recommended the designs submitted by Messrs. McKim, Mead & White, of New York.

HARTFORD, CONN.—Plans for the railway depot were considered September 13 by the Committee of New York and New Haven Railroad, and all rejected. Messrs. Clark and Reed were appointed a committee to employ an architect to prepare plans under their direction. The cost is limited to \$150,000.

ALLEGHENY, PA.—The High School Committee has received four plans for the new building on Sherman Avenue: from Joseph Anglin, L. O. Danse, Thomas A. Boyd, and J. W. Alston. The cost will be about \$50,000. No decision is yet made.

PRIZE PLANS FOR DRAINAGE.

The New Orleans City Council has before it the following resolution, presented September 6:

"Resolved, That the Comptroller be authorized and is hereby instructed to advertise once a week for four weeks for plans and specifications for improving and cleaning the drainage-canal of the city, with estimate of cost of work, and that for the best plan submitted the sum of \$4,000 be paid out of the first available funds collected of the reserve of 1883 to 1887, inclusive, and that this Council shall select two civil engineers of this city who, together with the city surveyor, will decide upon the best plan submitted, upon their award the said \$4,000 to be paid."

For works for which proposals are requested see also the "Proposal Column," pages 421-425-427-428.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE SANITARY ENGINEER AND CONSTRUCTION RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

WATER, SEWERAGE, ETC.

NUNDA, N. Y.—Our correspondent writes in regard to the building of water-works here that they will be built by a private company and will be in operation by November 15.

GRAND JUNCTION, COL.—The City Council has in contemplation putting in water-works. One plan is the "gravity system," taking water from the mountains twenty miles away. The other is the "Holly system," taking water from the Grand River flowing past the town. An election is called to vote on the proposition for or against water-works on the 13th of the present month.

HOLMESBURG, PA.—The contract for the water-pipe has been awarded to the Warren Foundry and Machine Company, Philadelphia, N. J., and the stand-pipe to Samuel Farmer, Harrisburg Boiler-Works, Harrisburg.

MAMMOTH SPRINGS, ARK.—The Mammoth Springs Improvement Water-Power Company has let a contract to Hiedelberg & Co., of Pleasanton, Kan., for a dam of stone across Spring River; price, \$18,000. J. M. Archer is Trustee for the Improvement Co.

MOBILE, ALA.—The works constructed by the Bienville Water-Works Co. (S. R. Bullock & Co., New York) were tested September 10 and found satisfactory. The cost was \$685,000. The works were constructed under direction of C. Delafield, Chief Engineer.

GALLIPOLIS, O.—The City Council has received from the Special Committee word that several water-works firms have been heard from, estimating the cost of works at \$50,000 to \$60,000. The matter will be voted on, at the city election, in November.

SUFFOLK, VA.—Our correspondent writes: "I am informed that the Portsmouth and Suffolk Water Company, of Portsmouth, Va., and the Suffolk Light and Water Company, of Suffolk, Va., are both anxious to make a contract with the town of Suffolk."

SACO, ME.—Incorporated are the Saco Water-Power Machine Shop; Clerk, Charles M. Moses, of Saco; Treasurer, Spencer W. Richardson, of Boston; and the Saco Water-Power Company; Clerk, Winfield S. Dennett, of Saco; Treasurer, George Dexter.

GREENVILLE, MICH.—Our correspondent writes in regard to the election on water-works: "The election has been postponed; think it will be held October 10."

CRETE, NEB.—Our correspondent writes that the opening of bids for constructing water-works has been extended to September 30.

WARR, MASS.—An agitation is started for a system of sewers.

SPRINGFIELD, ILL.—It is proposed to increase the water-supply by establishing filter-basins at the works. Peter Berriman is Superintendent of Water-Works.

WINCHESTER, CAL.—Incorporated is the Pleasant Valley Land and Water Company to operate principally at Winchester. The Directors are: William J. McEwen, William Hazlam, W. A. Lucas, J. H. Rice, J. Patterson, and Mrs. E. J. Rice, all of Winchester.

KAUKAUNA, WIS.—We have previously noted the progress of the movement for water-works here. Council has advanced the matter. Address the City Clerk.

CORPUS CHRISTI, TEX.—Our correspondent writes: "I have this day mailed to you a marked copy of the paper of our city, so you may see what action we have taken in regard to water-works. The committee is now awaiting bids for the work, which I think will be the boring of artesian wells. The Committee is J. Henry, George French, and O. C. Lovenskiold." The clipping reports a session of City Council August 30, at which the City Attorney read an opinion to the effect that the city had authority to establish a special tax for water-works and other improvements.

TOPEKA, KAN.—The Topeka Land and Water-Power Company was fully organized September 1. The following officers were elected: President, Colonel William Tweedale; Vice-President and Manager, Hon. S. K. Cross; Secretary, Colonel J. C. Douglass; Treasurer, Hon. H. E. Corwin. The purpose of this company is to develop the water-power of the Kansas River, damming it some twelve to fifteen miles above this city and bringing the water near here by a canal.

MARSHFIELD, WIS., will have sewers.

PORTSMOUTH, VA.—The water company has had an ordinance drawn, and submitted to City Council, relating to works.

BROOKLYN, O.—The State Infirmary Directors will build a sewer to the Cleveland line.

WEST STRATFORD, CONN.—There is difficulty about awarding the contract for the new sewers.

SAN DIEGO, CAL., will let contracts for 140,000 feet of sewer trenches. See our Proposals.

WHITESTONE, L. I.—It is proposed to obtain a supply of water from the College Point Company, and negotiations are going on.

MOUNT CARROLL, ILL.—At a special election held September 8 to bond the city five per cent. of assessment for the purpose of erecting water-works, the vote stood: For water-works, 271; against water-works, 58.

GALENA, ILL.—The Board of Aldermen of this city, September 9, adopted a resolution accepting the new artesian system of water-works just completed.

PETERSBURG, ILL., wants bids for constructing water-works. See our Proposals.

CHICAGO.—Incorporated is the Tulare Valley Improvement and Irrigation Company to irrigate and improve lands; capital, \$500,000. A. H. Pickering, H. A. Foster, Fowler B. Hill.

WATER-WORKS are in prospect at the following places: Farwell, Mich.; Ennis, Tex., artesian wells; Denton, Tex., artesian wells, address O. P. Roe; Cabery, Ill., cost \$30,000; Chambersburg, N. J.; Mount Vernon, Ill., bonds issued \$25,000.

PORTLAND, CONN.—Our correspondent writes: "I have to say that there will not be anything done about the water business until after the town meeting, October 3."

AUSTIN, ILL.—Our correspondent writes: "No official action has as yet been taken in the matter of erection or operating water-works."

YORKVILLE, S. C.—Our correspondent writes: "Have the water-works under consideration; do not think any steps will be taken at present to build them."

AMERICUS, GEO., Council Committee has rejected all the bids presented for the construction of water-works. The estimate was \$30,000, the lowest bid \$32,600. It is now reported that the city will employ a consulting engineer and build the works itself. Address the Mayor.

KROOK, IOWA.—George D. Rand has sold a controlling interest in the Keokuk Water-Works to the American Water-Works and Investment Company, of Pittsburg, Pa.

NORFOLK, NEB.—\$15,000 has been appropriated for sewerage and other work.

LANSINGBURG, N. Y.—In reference to previously reported increased supply of water, further information can be obtained from Commissioner Holmes, of the Water Board.

GAINESVILLE, TEX., will have a water-supply from artesian wells. Contractors Bell & Myers, of Denton.

OAKLAND, CAL.—The Spring Valley Water Company wants iron pipe for the mains which it will lay in Alameda County. Charles N. Fox is agent of the company in Oakland.

WILLIAMSBURG, IOWA, will provide water for fire protection, with a large tank or reservoir.

CHIHUAHUA, MEX.—Bids for constructing water-works are asked for until October 13. Address the Mayor, Don Juan Zubiran.

SHELL LAKE, WIS.—It is proposed to build water-works here.

KEARNEY, N. J.—We have already noted that this town will build water-works. Wade & Egan, contractors began work September 13, and expect to finish by October 31.

HAYWARD, WIS., will spend \$12,000 on its water-works.

BOSTON.—Much new sewer-work will be done under recommendations from the Mayor.

LONDON, ONT.—A proposition to raise \$150,000 for water-works purposes will be submitted by the City Council to a general election.

FLORENCE, WIS., will extend its water-works.

CHATTANOOGA, TENN.—We have already mentioned that much new sewer-work will be done toward establishing a general sewerage system. The Board of Public Works, in its recent report to the Mayor and Aldermen, estimates the length at about 34,000 feet, varying from 36-inch to 8-inch, the larger sizes of brick and the smaller of pipe. The cost is put at \$59,304.

TUSCOLA, IND.—On October 1 an election will be held on the question of raising \$26,500 for a system of water-works.

SOUTH PITTSBURG, PA.—Water-works will be built here. Address the South Pittsburg City Company.

NEW ORLEANS, LA.—Address the Superintendent of the New Orleans Water-Works about improvements to be made.

OWENSBORO, KY.—The water-works will be enlarged.

ANNISTON, ALA.—Address N. E. Moorehead about a large lake to be constructed here.

FORT WORTH, TEX.—O. M. Brown has the contract for enlarging the water-supply by sinking gang-wells.

SAUGERTIES, N. Y.—Under date of September 13, our correspondent writes: "Water-works are being constructed at this time, and will be completed in about two weeks."

EVANSTON, ILL.—The trustees have in consideration a plan for furnishing a supply of water for North Evanston. Address Trustee Grover, author of the plan.

TOPEKA, KAN.—Address Mr. Cross, President of the Water-Power Company, in regard to a project for damming Kansas River at Rossville. The dam will be about 800 feet long.

REYNOLTON BOROUGH, PA.—A committee has been appointed to ascertain the cost of providing a water-supply.

MYSTIC, CONN.—Water-works contractors should attend to this place at once. Prospectors are now on the ground looking over sources of supply for this town and Stonington.

ABERDEEN, DAK.—Our correspondent writes that no election was held on the question of constructing sewers.

GREENSBORO, N. C.—Owing to the illness of the chairman of the Water Commission, the contract for building water-works has not yet been awarded.

LAKE GENEVA, WIS., holds an election on the question of introducing water.

PORTLAND, ORE.—Incorporated is the Sunnyside Land and Improvement Company at this city. The capital stock of the company is \$100,000. The incorporators are: J. H. Smith, B. H. Bowman, and F. C. Goodin. The objects of the company include the right to construct roads, railroads, and street railroads to a point five miles east from Portland; also to equip and operate the same, build water, gas, and electric-light works, etc.

BROOKLYN, CONN.—Incorporated is the Ramapo Water Company, of this city, to supply Brooklyn and New York with water.

SPRINGFIELD, ILL.—The water-works will be enlarged. Address the City Engineer for further information.

JERSEYVILLE, ILL., will obtain a supply of water from artesian wells.

MARQUETTE, MICH.—A proposal will be found elsewhere for constructing certain parts of the main sewerage system of this city, after plans by Chester P. Davis, of Chicago, Consulting Engineer. The separate system will be used; about 1½ miles will be built.

DUBUQUE, IOWA.—For the sewerage-work here, already referred to, proposals are now issued, which will be found elsewhere in this issue. There will be about 10 miles of work, on the separate system, after plans by Chester B. Davis, of Chicago, who is the Consulting Engineer.

SAVANNAH, GEO.—Our correspondent writes: "The city of Savannah has just completed 13 artesian wells, as follows: 1 4-inch well, 1 10-inch well, and 10 6-inch wells. The flow from these is about 6,000,000 gallons every 24 hours. There is some talk of boring three wells more. The city does her own work in boring and fitting."

PHILADELPHIA.—\$25,000 will be spent for laying iron water-pipe to connect East Park Reservoir with the city mains.

NATCHEZ, MISS., has taken adverse action on the matter of constructing sewerage.

NORTHAMPTON, MASS.—The Aldermen have voted to adopt the "Shedd plan" of sewerage, which was proposed in 1882. The estimated cost is \$480,000 to complete the work. Address the City Engineer.

REED CITY, MICH., has decided to have a system of sewers constructed. Address the City Clerk at once.

CAMDEN, N. J.—The City Council of Camden, N. J., offers for sale a Cornish pumping-engine, 21 inches plunger, 41-inch cylinder, 7-foot stroke, built to lift 3,000,000 gallons in 24 hours. The pump is located at PAVONIA, N. J.

SANTA CRUZ, CAL., will expend \$60,000 for water-works, sewerage and other improvements.

SAN LUIS OBISPO, CAL., has in prospect the construction of water-works, sewerage, street-work, and parks.

FARGO, DAK.—Hon. Alexander McKenzie may be addressed about the water-works now building.

NEW HAVEN, CONN.—The City Engineer will advertise at once for bids on the Boulevard Sewer.

MONTELEONE, VT.—On September 26 a town meeting will be held to decide on increasing the water-supply by a new iron main.

PROVIDENCE, R. I., City Council has passed the following resolution: "That the City Engineer cause borings and soundings to be made on location of the main line of the sewers, pump works, and precipitation tanks, outfall, etc., and also prepare detailed plans of the various parts of the work necessary for carrying into effect the sewerage plan as adopted by the City Council, the expense of the same to be charged to the appropriation for sewers."

MILWAUKEE.—City Engineer Benzenberg has prepared plans for the flushing tunnel. It will be run 2,440 feet from the lake to the river in Dane Place. It will be of brick, twelve feet in diameter, and will cost \$100,000 exclusive of the pumping works, which will be located on the lake shore about opposite the Dalrymple farm. The entire sewer will be beneath the water line and the water will be lifted by the pumps three feet; 300,000,000 gallons of water per day will be pumped and 300 horse-power engines used. The Finance Committee of Council has decided to recommend \$25,000 for constructing the tunnel.

PORTSMOUTH, VA.—City Council has finally come to an agreement and entered into contract with the water company.

BARRE, VT.—The Barre Water Company, chartered by the last Legislature, has arranged with Goodhue & Birnie, of Springfield, Mass., to supply Barre Village with water by July 1, 1888. On completion of the works the town has the option of purchasing them within sixty days at an advance of 10 per cent. on their cost.

PLYMOUTH, MASS.—A town meeting was held September 12, with William T. Davis as Moderator. The warrant related to the adoption of an act of the Legislature permitting the town to provide a system of sewerage. A committee was appointed to report a bill at the next March meeting.

CORTLAND, N. Y.—Sewer contractors should observe events here. Sewerage wanted.

HAYWARD, WIS.—Our correspondent writes: "No particular steps have yet been taken in regard to the water-works, except that H. H. Harrison, of Stillwater, is drawing up the plan and specification for said water-works. The contract for putting it in will be let to lowest bidder."

HUDSON, WIS.—Our correspondent writes in regard to water-works: "Artesian well down about 150 feet, flow of water 150 gallons per minute; about one mile of pipe laid, and the work being pushed with vigor. Foundations are in for pumping station; nearly all material and appliances on the ground and expect to complete the work before winter. We expect a flow of 400 or 500 gallons per minute when complete of pure water. Appropriation of \$20,000 for the works. They probably will exceed that amount."

NICKERSON, KAN.—Mayor S. R. Marshall will receive bids until September 26 for constructing water-works.

MANKATO.—The City Council has awarded the contract for building a reservoir for the water-works to Adam Jefferson for \$4,550; 2,300 feet of pipe, to connect mains with the reservoir, were ordered purchased.

ST. PAUL.—Sewer on Colborne Street, from St. Clair to Superior, White & Adams, \$2,100; sewer on Colborne Street, from Seventh to Jefferson, Hans Hansen, \$1,760; sewer on Aurora Avenue, E. J. Kirkland, \$42,975.

LODI, CAL.—The directors of the Makelumne Ditch and Irrigation Company have decided to complete the dam on Makelumne River. Bids will be asked for very soon.

ROCHESTER, N. Y.—Common Council has employed Emil Kuichling, C. E., to make plans and specifications for the East Side sewer.

KAUKAUNA, WIS.—An engineer has been employed to make a report on water-works.

MARION, IOWA.—Our correspondent writes: "The city does not own or operate our water-works, but they are owned and controlled by a local company, who are now completing it by laying about three miles of additional pipe or mains."

FORT WAYNE, IND.—The Water Trustees have recommended that a contract be made with the Holly Manufacturing Company, of Lockport, N. Y., for a 6,000,000-gallon Gaskill pumping-engine; cost, \$27,650. The matter is referred to the Finance Committee of Council.

ST. IGNACE, MICH.—Address the Water Commissioners about proposed water-works here.

BOONE, IOWA, will have water-works.

FENTON, MICH.—C. W. Coe may be addressed about water-works.

GAS AND ELECTRIC-LIGHTING.

LAKE, ILL.—The Town Council is considering a proposal of the Economic Heat and Gas Company to furnish illuminating power of 125 candles for \$1.50 per 1,000 feet, heating gas at \$1.25 per 1,000 feet, and gas for public lamps at \$1.25 per 1,000 feet. President Sherwood stated that his company would light the street lamps at \$22.50 a lamp.

SAN ANTONIO, TEX.—The city has made a two years' contract with the San Antonio Gas Company to maintain 50 arc-lights at \$14.40 per month and 200 gas-lights at \$2 per month.

IOLA, KAN.—Natural-gas has been discovered here and a well sunk.

WHITESTONE, L. I.—The New Jersey Globe Gas-Light Company, of New York, has made an offer to erect 50 lamps and light them 22 nights each month for \$16.75 per lamp per annum. A contract will be made with the company.

SANDUSKY, O.—The City Council is considering the abolishing of gas and the introduction of electricity for street-lighting.

DETROIT, MICH.—The Edison Power and Light Company let a contract September 9 for the building of a water-power canal along the rapids of the St. Mary's River at Sault Ste. Marie. The canal will be about 2,000 feet long and 50 feet wide. Its object will be to furnish, by the use of great water-power, electric power with which to run elevators, mills, and an endless variety of other machinery and an electric-light plant.

SEWARD, NEB.—has decided to have electric-lights in the streets.

TAMPA, FLA.—The city has contracted with the Tampa Electric-Light Company to maintain arc-lights at 60 cents per lamp per night.

WEST BAY CITY, MICH.—City Council has awarded the contract for lighting the streets to the West Bay City Electric-Light Company at \$77 per lamp yearly.

ORANGE, N. J.—Articles of incorporation of the Edison Illuminating Co., of the Oranges, were recorded September 11. The incorporators are: Gilbert R. Hawes, Thomas A. Edison, Edward A. Pearson, Eugene S. Kaas, and Thomas Marsh. The object of the company is to furnish electricity for lighting, heat, and power in Orange, East, West, and South Orange.

MORRISTOWN, N. J.—The Common Council on September 12 opened bids for lighting the streets, as follows: The Morristown Gas-Light Company made three propositions, the first to furnish 4-foot burners twenty-six nights a month for \$22.50 a year. This is the same service that was given last year for \$26. The second proposition is for 6-foot burners for the same number of nights for \$27, and the third is for all night and every night in the year at \$27. The Electric-Light Company offered to furnish incandescent lights of 25-candle-power every dark hour for \$17.50 for each light a year, and arc-lights, not less than twelve in number, at \$10 each per month.

YOUNGSTOWN, O.—Just organized is the Home Gas and Fuel Company to lay gas-mains in the city.

WINCHENDON, MASS.—A town meeting is being held to-day to see if the Selectmen shall take action to secure electric-lights in the streets.

GAINESVILLE, FLA.—The Electric-Light Company has received a franchise for lighting the streets. Address W. J. Winegan.

BRYAN, O.—The Fountain City Oil and Gas Company, of Bryan, increases its stock from \$10,000 to \$100,000 for improvements.

UTICA, N. Y.—The certificate of incorporation of the Citizens' Mutual Heat, Light, and Power Company, of Utica, was filed in the Clerk's Office September 13. The object is the manufacture of electricity for light and power, and distributing fuel-gas, hot water, hot air, and steam. The trustees for the first year are: George D. Dimon, John B. Wild, Isaac R. Scott, John Caney, and William S. Doolittle. Work on the plant will be pushed.

BERKELEY, CAL.—The citizens have formed a company to establish an electric-light plant. Address R. P. Thomas, of the Standard Soap-Works, at once.

SPARTA, WIS.—A company is forming to establish an electric-light plant.

LOGAN, O.—Steps will be taken to provide the necessary plant to utilize the gas from the wells for heating and lighting.

LUDINGTON, MICH.—This city will introduce electric-lighting for the streets.

CEDAR RAPIDS, IOWA.—Articles of incorporation of the People's Light and Power Company, of Cedar Rapids, were filed September 9. The officers are: C. J. Ives, President; W. J. Greene, Secretary; and J. B. Bever, Treasurer. Electricity will furnish the basis.

JACKSON, MICH.—The ordinance relating to electric-lighting, which was vetoed by the Mayor, has been passed over the veto by City Council.

CALDWELL, KAN.—An electric plant will be established here for street-lighting.

TOPEKA, KAN.—The Brush Electric-Light Company has made a proposition to City Council for extra lighting.

NORFOLK, NEB.—An appropriation has been made for electric-lights for the streets.

ALGERS, LA.—An electric-light plant will be established here by the Louisiana Light and Power Company, of New Orleans.

BRAINARD, MINN.—will have electric lights. The plant has been purchased.

SUMTER, S. C.—On September 7 City Council discussed a proposition from the Maryland Electric Motor Manufacturing Company to light the streets with electric-lamps. No action was taken, but a contract will probably be made.

DUNDER, MICH.—Address J. S. Dixon, President of the local company, about plant for sinking oil and gas wells.

WATERVILLE, ME.—It is proposed that the town shall buy the plant and franchise of the Waterville Electric-Light Company. The price is put at \$30,000.

BELVIDERE, ILL.—Incorporated is the Belvidere Electric-Light Company: capital stock, \$8,000; incorporators, S. L. Coney, Frank W. Plane, Charles E. Fuller, and others.

ALLENTOWN, PA.—On September 20 Mayor W. K. Ruhe will open bids for lighting the streets with gas, electricity, naphtha and oil. At the same time bids for lamps and lamp-posts will be opened.

JAMESTOWN, DAK.—will introduce electric street lighting.

GREENBUSH, N. Y.—has contracted with the East Albany Gas Company to light the street-lamps and keep them in repair for \$2.75 per 1,000 cubic feet.

PALMER, MASS.—A gas company is to be formed here to supply both Palmer and Monson.

VIRGEN, ILL.—The Virgen Gas and Oil Company is just organized, to bore wells for oil and gas.

LAKE, ILL.—A franchise has been given to the Economic Heat and Light Company, for the laying of mains and furnishing of gas.

COLUMBUS, GEO.—City Council, September 13, awarded a contract to the Brush Electric-Light Company at \$108 per light per annum.

STEAM-HEATING, BUILDINGS, ETC.

WALDO, TENN.—\$40,000 will be expended on buildings and machinery for a cold-storage plant. Address Fred Balcom.

BRIDGES.

UPPER DARBY, PA.—The County Commissioners will build a bridge here.

HIGGINSVILLE, N. Y.—A bridge will be built by the County Commissioners.

JEFFERSONVILLE, KY.—A bridge will be built. Address Dennis Long.

OLD ORCHARD BEACH, ME.—It is proposed to build an iron pier here 1,300 feet long, 25 feet wide, with electric-lights, etc. Address Henry Staples, of the Old Orchard House.

SANTA FE, N. M.—Address the City Engineer, who has prepared plans for two additional bridges over the Galisteo and the Rio Grande.

NORRISTOWN, PA.—Bids are asked for a bridge over the Wissahickon.

NEWBERNE, N. C.—A bridge is wanted. Address at once the Clerk of the County Commissioners.

FRONT ROYAL, VA.—A bridge will be built. Address W. L. Garrison at once.

TOPEKA, KAN.—City Council has passed resolution directing the City Engineer to furnish plans and estimates for an iron bridge over the Kansas River on Kansas Avenue.

CAVE SPRING, GEO.—It is proposed to build a new bridge on Bridge Street. Address the County Engineer of Floyd County at the county seat in Cave Spring.

AUBURN, R. I.—Dean & Westbrook, of Brooklyn, N. Y., have received the contract for iron work of the bridge to be built over the Pawtuxet River, at Elmwood Avenue, and J. Dailey & Sons the contract for stone work. The bridge will be of iron, 140 feet long and 20 wide. The cost will be about \$10,000.

ALBANY, N. Y.—On September 13, Superintendent Shanahan, of Public Works, awarded contracts for bridges in Buffalo as follows: That at Austin Street to McLean & Rockwell, of Syracuse, for \$4,224.50, and that at Hudson Street to D. W. McConnell, of Buffalo, at \$6,663. There were four bidders for the Hudson and three for the Austin Street.

BROCKPORT, N. Y.—Another bridge will be built over the Erie Canal at Main Street. Proposals will be issued at once.

EAU CLAIRE, WIS.—At a special meeting of the Council, September 12, a resolution was adopted for the appropriation of \$6,120 for the construction of an iron bridge of two 100-foot spans across the Eau Claire River from Dewey Street. The contract for building the structure was awarded to Horace Houghton, of Rochester, Minn.

SIDNEY, NEB.—Cheyenne County is preparing to build three bridges over the Platte River; cost \$45,000.

FOND DU LAC, WIS.—The Aldermen have passed ordinances providing for the building of two bridges. Address the City Engineer.

POTTSVILLE, PA.—Bids for a bridge over Middle Creek are wanted. See our Proposals.

AUSTIN, TEX.—Address the County Commissioners in regard to a proposed iron bridge over Colorado River here.

FOND DU LAC, WIS.—In our Proposal Columns will be found a notice relating to an iron bridge over Fond du Lac River.

ROCKVILLE, CONN.—A new bridge is being built on the Connecticut River at West Street. Selectman Fitzgerald is doing the work.

SHAWNTOWN, EAU CLAIRE CO., WIS.—It is proposed to build a bridge over Half Moon Lake, to cost \$25,000. Address the Commissioners of Eau Claire County.

DETROIT, MICH.—Bids for building the Belle Isle Bridge were opened by the Board of Public Works, September 10, as follows: Keystone Bridge Company, \$375,630; George Farwell, Detroit, \$335,000; Detroit Bridge and Iron-Works, \$330,000; King's Iron Bridge Company, Cleveland, \$343,000; Morse Bridge Company, Youngstown, O., \$360,000; Milwaukee Bridge Company, four propositions, as follows: \$287,000, \$305,000, and two at \$295,000.

MANASQUAN, N. J.—At the meeting of the Board of Chosen Freeholders of Ocean County it decided to cooperate with the Monmouth County Board in building a new bridge across the Manasquan.

ALMY, WYO.—A new bridge is to be built over the Bear River here, on the Woodruff Road.

NEWARK, N. J.—The Improvement Association of the Eight Ward, Newark, are considering the desirability of building a new bridge across the Passaic at Third or Fourth Avenue.

NORTH EAST, MD.—An iron bridge will be built over Main Street. Address the County Commissioners.

BROOKLYN BRIDGE.—Look out for proposals for elaborate work at the terminals of the Brooklyn Bridge: plans by Engineer Shunk.

SAN FRANCISCO, CAL.—The Chief Engineer of the Harbor Commission is preparing plans for a pier 340 feet long and 100 feet wide.

BRIDGE.—The New York, New Haven, and Hartford Railroad has contracted with the Consolidated Bridge Company, of Pittsburg, for a bridge over the Connecticut River, at Lyons, to cost \$100,000.

BRIDGES.—The Port Jervis, Monticello, and New York Railroad will begin work at once, including the construction of a number of bridges, for which contracts will be given out. The president of the road is Henry R. Low.

CHICAGO.—Fitz Simmons & Connell are awarded, by the North Chicago Street Railroad Company, the contract to build the substructure for the new Dearborn Street bridge for \$30,000.

City Engineer Artingstall, of Chicago, by order of Mayor Roche, is figuring out the cost of a four-tracked steel bridge, turned by steam, at Madison Street and the Chicago River. A popular estimate is \$1,500,000, not including necessary land condemnations.

WOODLAND, CAL.—The Supervisors have contracted with the San Francisco Bridge Company to build a bridge over Cothe Creek to be 600 feet long; price, \$7,000.

NEW HAVEN, CONN.—The City Engineer will advertise at once for bids for constructing a stone arch bridge at Rock Lane. The estimated cost is \$20,000.

BRIDGES will be built as follows: The Atchison, Topeka, and Santa Fe Railroad Company will build a bridge at Lexington, Mo. George L. Sands, Topeka, Kan., General Superintendent.

The County Commissioners will build a bridge across the Oconee River, at Dublin, Geo. The Boston and Maine Railroad Company will build a bridge across the Merrimac River, at Newburyport, Mass. James T. Furber, Boston, General Manager. The Commissioners of Rome, Geo., will build a bridge over the Oostanula River at that city.

WALLULA, W. T.—A bridge will be built over the Columbia River at this place.

ST. PAUL.—The City Council has awarded the contract for constructing the Colorado Street bridge to O'Brien Bros. for \$26,895.

PITTSBURG, PA.—Josiah Speer, County Controller, will receive bids until September 21 for approaches to a bridge over Peter's Creek.

STREET WORK AND PAVING.

AKRON, O. wants bids, until September 24, for street-work.

SAN DIEGO, CAL.—The County election on the 5th, to decide the issuing of bonds for highway improvements, went in favor of raising the funds, and the work will be done.

NORFOLK, VA.—The Street Committee has decided to pave Granby Street with Belgian block, and an appropriation of \$30,000 will be made. Contracts will be made at once.

CINCINNATI, O.—Improvements will be made on Crawford Creek Road, for which proposals are wanted by the Board of Public Affairs.

STEAM stone-crusher and steam road-roller is wanted by Lancaster, Pa. Address bids, until October 3, to the Street Committee of Councils. Apply for further information to the City Clerk.

TRENTON, N. J.—Humboldt Street will be extended.

NEW LONDON, ONT.—On 3d October City Council will consider undertaking the enlargement of Water Street.

PITTSBURG, PA.—Much street-paving, sewerage, and opening is before City Council, and are likely to pass. The cost will be about \$40,000.

HARRISBURG, PA.—The city has contracted with the Barber Asphalt Paving Company to pave and curb Market Street, at \$2.75 per square of paving and \$1.50 per lineal foot for paving.

BETHLEHEM, PA.—The Street Committee of Council has just closed a contract with Farrell & Worsden for a stone-crusher, and will do a good deal of street-work at once.

LAKE VIEW, O.—Considerable street-paving has been ordered done by City Council. Address the Board of Public Works.

MILWAUKEE.—Bids will be received by the Board of Public Works to put in new stone curbing on Twelfth Street, from Grand Avenue to Cedar Street, about 1,600 feet of curbing; new sidewalks on First Street, from North Avenue to Lee Street, 600 feet; improving Eighth Street, from Locust to Burleigh Streets; improving Conway Street, from Kinnickinnic Avenue to Logan Avenue.

NEW HAVEN, CONN.—The Board of Public Works will soon take action on paving Temple Street with asphalt.

CLEVELAND, O.—Bids will be opened September 22 by Walter Rice, City Engineer, for Medina stone pavement on Case Avenue.

NORFOLK, VA.—\$15,000 has been appropriated to pave Holt Street with Belgian block, and \$30,000 to pave Granby Street with same material.

SOUTH FRAMINGHAM, MASS.—The town has voted to apply \$10,000 to repairing the road to Saxonville. Address S. B. Bird, Moderator.

FARGO, DAK.—The City Engineer has prepared plans and estimates for a subway under the Northern Pacific Railroad track at Broadway.

LANCASTER, PA.—Street contractors and paving material men should watch for result of discussion on the paving of some of the principal streets which is now going on in City Council.

OKLAND, CAL.—Filbert Street will be graded and paved.

CONY ISLAND, N. Y.—The Brooklyn Park Commission will have a sea-wall built at Brighton Beach, involving a considerable outlay.

GRAND RAPIDS, MICH.—Improvement of East Street let to Richard Pickett at \$16,000.

LANSINGBURG, N. Y.—Address the City Engineer in regard to bids on repaving certain streets, including Sixteenth and Seventeenth Streets.

HOLBROOK, MASS.—Considerable grading and street work will be done here, and town meeting September 9 voted to employ an engineer to make plans and estimates.

LAKE, ILL.—The Town Trustees have awarded a contract for improving State Street to Dollse & Shepard, at about \$45,000.

RAILROADS, CANALS, ETC.

NEW YORK CITY.—A proposal for the lowering of the tracks of the N. Y. C. R. R. in the 23d and 24th Wards has been made by the Park Commission to the Railroad, and a plan about agreed upon. It is estimated that the cost will be \$2,000,000, and that work will be soon begun.

MARION, IND.—The annual election of a board of nine directors for the Marion and Indianapolis Railroad was held August 19, resulting in the choice of the following: William Garver, of Noblesville; Eli Goodman, of Hackleman; J. W. Parsons, of Independence, and Cyrus W. Gibson, Moses Bradford, Marshall F. Fingley, James Brownlee, D. W. McKinney, and David Overmann, of Marion. The Marion and Indianapolis Railway was organized in January, 1881, to build a line from Marion to Indianapolis. The board of directors will meet here for organization, and to decide on a plan of action.

POUGHKEEPSIE, N. Y.—Articles of incorporation of the Poughkeepsie, Hartford, and New England Railway Company, which proposes to construct a line from Poughkeepsie to the Hartford and Connecticut Railroad, have been filed. The directors are: James W. Husted, of Peckskill; John I. Platt, Ezra White, and Peter Hulme, of Poughkeepsie; George W. Green, of Goshen; Henry Gay, of West Winsted; William Gibbs, of Philadelphia; Edward McNeill, of Hartford; Henry H. Boddy, Elverton R. Chapman, David J. McNiece, and William R. Carlisle, of New York, and Charles H. Swan, of Brooklyn.

ATLANTIC CITY, N. J.—The Cape May County garden farmers have for several years been supplying Atlantic City with fresh vegetables. The trip has been unusually slow, as only small boats could be used on account of there being no direct deep channel in the inland waters. With a view of securing quick transit with large boats the truckers have secured the services of a surveyor who is now looking into the possibility of a direct route.

ONEONTA, N. Y.—The Oneonta and Otsego Valley Railroad Company, to be operated from Otsego to Oneonta, distance 28 miles, has been incorporated. The directors are Sidney Dillon, Arthur W. Soper, William R. Thomas, New York.

PITTSBURG, PA.—The Electric Street Railway Company will increase its stock by \$75,000 to add to its plant.

FLUSHING, N. Y.—The Flushing and College Point Surface Railroad Company has decided to begin operations at once. The first work to be let will be the grading and laying of the rails. The cars of the company will be run by electricity, probably on the storage-battery plan. Joseph L. Dykes is President and Chairman of the Construction Committee; Henry Clement, Treasurer; Arthur Fleming, Secretary, and Joseph K. Murray, Counsel.

BEAVER, PA.—A dike will be built across the Ohio River at this place for the Pittsburg and Lake Erie Railroad. A. E. McKinsie, of Ashtabula, O., is the contractor.

PENSACOLA, FLA.—The Pensacola Gulf, Land and Development Company was organized September 6. The officers of the company are: J. C. Petterson, President; S. N. Vanpraag, Secretary; W. A. Delemberte, Treasurer.

QUINCY, ILL.—Incorporated is the Quincy and Rock Island Railroad Company, the principal office at Quincy, and the amount of capital stock to be \$2,000,000. The incorporators are Charles A. McLaughlin, of Galesburg; Sam S. Gray and Charles R. Arnold, of Hamilton; Charles H. Drere, of Moline; Morris Rosenfeld, of Rock Island; George W. Jretzinger, of Chicago; James M. Bishop, of Quincy; James T. Crawford and William Hill, of Warsaw, Ill.

MINNEAPOLIS, MINN.—Incorporated September 6 was the Continental Cable and Street Railway Company. The principal office is in Minneapolis. The capital stock is \$100,000, and the incorporators are Horace P. Breed and W. B. Tibbits, of Minneapolis; William S. Crosby, of Chicago.

NEW YORK CITY.—Plans for lowering N. Y. C. R. R. tracks in the 23d and 24th Wards will be on exhibition at the Park Department until October.

SACRAMENTO, CAL.—The City Trustees of Sacramento, at a meeting September 6, granted a franchise for two additional street railways, one to Alais & Lewis and the other to Frank N. Myers.

ASTORIA, ORE.—Address J. Q. A. Bonlby, President of the Chamber of Commerce, about a new railroad to be built to connect with the transcontinental lines; \$150,000 has been raised by the city as a bonus.

LEAVENWORTH, KAN.—City Council has granted the application of the Rapid Transit Railway for permission to build a line to the suburbs.

PHILADELPHIA.—The Pennsylvania Railroad will receive proposals for the grading of two additional tracks 2½ miles long on their New York Division from Cornwell to Schenks; also, for the erection of proposed "shops" at Camden, N. J., on the Amboy Division, consisting of erecting shops, paint shop, planing mill, and boiler room, all exclusive of foundations, plumbing, gas-fitting, asphalt floors, and boiler shop.

DULUTH, MINN.—The Duluth and Iron Range Railroad will be extended and connection made with the Canadian Pacific.

MOBILE, ALA.—Dredge men should observe the action of the directors of the Cotton Exchange in reference to deepening the harbor. The Secretary can give further information.

JEFFERSONVILLE, KY.—Articles of incorporation have been filed of the Jeffersonville and Ohio Falls Street Railway Company. The capital stock is fixed at \$40,000. The incorporators are G. W. Baxter, E. V. Stealey, Jacob S. Fry, Henry Burt, and James H. McCampbell.

HALIFAX, N. S.—Messrs. Thomas C. Connor and R. C. Donald, of Moncton, have been awarded the contract for rebuilding the railway wharf at Richmond, Halifax. The contract price is understood to be in the vicinity of \$50,000.

RAILROAD.—The contract for building the Tennessee and Mississippi Rivers Railroad has been let to D. S. McIntyre, of Corinth, Miss.

LAMAR, MO.—The Denver, Memphis and Atlantic Railroad will build into this city.

KNOXVILLE, TENN.—The charters of incorporation were filed September 12 for two new railroads. The charter members consists of A. A. Arthur, and others. The roads are Careyville, Jackboro, and Big Gap and the Jellico and the Cumberland Gap Road.

MILWAUKEE, WIS.—The Milwaukee City Railway will extend its tracks. The Milwaukee and Wauwatosa Cable Company has been granted a charter.

THE SANITARY ENGINEER AND CONSTRUCTION RECORD.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1887, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 16. }
NUMBER 17. } PUBLISHED EVERY SATURDAY.

NEW YORK, SEPTEMBER 24, 1887.
LONDON, OCTOBER 8, 1887.

SINGLE COPIES, TEN CENTS.

SINGLE COPIES, SIXPENCE.
Subscription, 20s. per annum in advance, post paid. } IN GREAT BRITAIN.

THE SANITARY ENGINEER AND CONSTRUCTION RECORD, conducted by HENRY C. MEYER, is published every Saturday at 82 & 84 Fulton Street, New York. Its opinions upon all technical subjects are either prepared or revised by specialists.

TERMS, \$4 PER YEAR, IN ADVANCE.
Postage Paid.

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.

TERMS, 20s. PER YEAR, IN ADVANCE. Postage Paid.
SINGLE COPIES, SIXPENCE.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE SANITARY ENGINEER AND CONSTRUCTION RECORD (New York), and crossed ——— & Co.

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzig, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, \$5; China, Japan, Sandwich Islands, Mexico and Cuba, \$5; South America, \$5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us promptly of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money order payable to THE SANITARY ENGINEER AND CONSTRUCTION RECORD.

When a change of address is desired, both the old and new addresses should be given.

PECULIAR METHODS IN THE DISTRIBUTION OF THE NEW CROTON AQUEDUCT REPORTS.

FOR several years past American engineers having large engineering problems under consideration have visited Europe to personally inspect works and gather information impossible to obtain in published reports, in order that their clients, the different cities of the United States, might profit by the experience of communities on the other side of the water, and, so far as possible, be spared the expense involved in experimenting in unknown fields. Speaking for ourselves, as well as others with whom we are acquainted, we can truly say that, without exception, European engineers have taken unusual trouble to give us information, giving their time freely and affording every facility to engineers who have visited them properly accredited. They have done this entirely from a professional feeling that an engineer should give his fellow freely the benefit of his experience in matters of this sort. And more, they have frequently answered personal letters, giving valuable data without hope or expectation of any pecuniary reward. Had a title of this information been sought for by a city or a commission in charge of any public work, a handsome fee would have very properly been expected. So far as we know, no American community has ever paid a dollar for any information thus acquired. When European engineers, however, come to this country, our engineers will of course be glad to show similar attentions to them.

Yet up to this time in sanitary engineering our engineers' only opportunity of reciprocating has been by sending, with their personal compliments—not compliments of a commission—copies of their reports to the gentlemen who have afforded them facilities for obtaining valuable data. This is indeed our engineers' only method of indicating that courtesies received have not been forgotten.

When Rudolph Hering visited Europe to report upon the sewerage systems there, he was greatly indebted to a number of engineers, and yet when his report was published by the National Board of Health it was impossible for him to secure a single copy to send to the gentlemen to whom he was thus indebted. Such volumes as were published, however, found their way into the hands of people of supposed political influence or their friends, and the men who had most need for them could not get them for love or money. Some three weeks ago we noticed with approval the report of the Chief Engineer of the Aqueduct Commission on the progress of the work on the new Croton Aqueduct, commending the commissioners for placing before the profession a work containing this valuable data. This community have had in their employ engineers who have visited Europe and who also have written to personal friends for data affecting the problem of the construction of high masonry dams. The information secured would not have been given to this city or to the commissioners without compensation, yet it has been freely given in private correspondence to gentlemen who have been able to utilize it for the benefit of this city. It is now some six weeks since the Aqueduct Report was published, and the distribution of the volumes has been put in the hands of a sub-committee of

the Commission, consisting of William Dowd, Hamilton Fish, Jr., and E. L. Ridgway, yet at last accounts the engineers of the Commission had been unable to secure the volumes that should have been promptly given to them before a single copy was given or sold to any one else, so that they might have been enabled to send a copy to the engineers to whom they are personally indebted for courtesies received.

Besides, this committee have been unable to decide, until within a few days, what price they wanted American engineers to pay for them. After waiting some weeks, we secured several copies last week, to send to gentlemen in Europe, by paying five dollars apiece for them, yet we learn that several hundred of these volumes have been freely given to politicians and their friends. Since two engineers are members of the Commission, it is unfortunate that these two gentlemen were not on the committee, since they would have been able to appreciate the propriety of doing what the present committee are clearly incapable of recognizing. It is perfectly proper that the volumes should be sold to anybody who may want them, but before any volumes are sold, the engineers that have been employed by the city should be requested to furnish a list of the gentlemen to whom they are indebted for information, and to such they should be permitted to send, with their personal compliments, a copy of this report. After that obligation is met, a price can be designated at which volumes may be sold.

In this connection it is a pleasure to commend the action of the authorities of the city of Providence as a gratifying exception to the methods we have here criticised. When their engineer makes a report, which reports are always of value, they make a liberal appropriation for their publication, and they allow him to designate, to a large extent, where these reports shall be sent. On the other hand, our Aqueduct Commissioners seem to think that politicians and their friends are the only people to whom they are in any way indebted.

FIRE PROTECTION IN PARIS THEATRES.

FROM *Le Genie Civil* we learn that, after the burning of the Nice Theatre, the Prefect of Police put forth an ordinance to regulate the construction and management of theatres. The police have found it impossible to enforce these ordinances without closing the theatres owned by private proprietors, as these proprietors preferred to pay the fines imposed upon them for non-comformity with the regulations rather than expend the sums necessary to obey them.

The directors of the Government and municipal theatres have been, until the burning of the Opera Comique, unable to get appropriations to carry out fully the works required by the new law, although certain attempts were made in the municipal theatres and in the Grand Opera House to conform to the principal conditions of the ordinance.

M. Chenier, who has given much study to the subject, blames the public for the disregard which the managements have shown for these ordinances; for the theatre-goers do not demand the most thorough guarantees of safety and are content, not only with crowding and discomfort, but with exits most insufficient in case of fire.

Le Genie Civil suggests that the police should fix posters, warning the public, at the entrance of all places of amusement which do not conform in their construction and management to the city regulations, as a better means of enforcing those regulations, than by fining the proprietors or closing the theatres. The new regulations will be found elsewhere in this issue.

REAL RAPID TRANSIT.

THE Rapid Transit Commission of this city have, in a report to the Mayor, recommended as a solution of the rapid-transit problem what THE SANITARY ENGINEER AND CONSTRUCTION RECORD has for several years been advocating—namely, a solid viaduct line on property bought and paid for. They submit their conclusions as follows:

"We are led to the conclusion that there is but one way to obtain such rapid transit, and that is by the construc-

FROM WALL STREET	Distance. Miles.	Time. Minutes.
To City Hall.....	$\frac{1}{4}$	$1\frac{1}{4}$ to $1\frac{1}{2}$
To Union Square.....	$\frac{1}{2}$	5 to 6
To Madison Square.....	$\frac{3}{4}$	6 to 7
To Forty-second Street.....	$3\frac{1}{4}$	9 to 10

The longer the building of a road of this character is put off the more it will cost, since the property needed will materially increase in value.

PHILADELPHIA PUBLIC SPIRIT.

TWO GREAT national events have been celebrated in Philadelphia in the last eleven years, the second but a few days ago. That city deserves to be congratulated, because the success of her celebrations is due to her being a thoroughly American city, and possessed of a proper pride in her past and her historical monuments. A few New York citizens and newspapers now and then amuse themselves with projecting some national celebration—in 1889

TESTING ZALINSKI'S PNEUMATIC GUN.

A TEST was made on Tuesday of the effect on a vessel of the explosion of the dynamite shells thrown from the air-gun, or cannon, devised by Lieutenant E. L. Zalinski, U. S. A. The schooner "Silliman," an old wooden Government vessel, was anchored about a mile and a quarter from Fort Lafayette, New York Harbor, where the gun is being tested. After two shots had been fired to get the range, a shell containing fifty-five pounds of explosive gelatine and dynamite was fired, striking the water very near the vessel. The explosion took one of the schooner's masts short off, damaged her wood-work, and threw a large quantity of water on her decks and into the hold. A second fifty-five-pound shell exploding near the hull, shattered it badly, the vessel sinking immediately. The test was made in the presence of Secretary Whitney, U. S. N., and several officers of the army and navy, and other scientific gentlemen. The result was considered a success, and Lieutenant Zalinski was warmly congratulated.

CLUB HOUSE AT GLEN RIDGE, N. J.—WILLIAM CONVERS HAZLETT, ARCHITECT.

tion of a solid viaduct line through the blocks, as far as possible, and when compelled to cross or follow the lines of streets to be constructed with much greater strength and solidity than the present elevated railroads. Such a viaduct road should be built in accordance with the following conditions:

"First—The structure should be built through the blocks of brick and stone in the most solid manner. The streets should be crossed by massive steel girders with solid steel floors, having no openings. The track should consist of heavy steel rails on ties laid in an elastic material between floor and ties. There would be no jar or break of continuity of motion in such a structure, and trains could be run at high speed with little noise.

"Second—The stations should be not less than one-half mile apart and long enough for ten cars. The cars should be as wide as possible.

"Third—Trains should be run by independent motors, and as frequently as on the elevated roads, and at a speed of at least twenty-five miles per hour, including stops. This would enable the trip to be made—

for instance—and then nobody cares, the effort falls flat, and New Yorkers buy railroad tickets to another town. The difference seems to be that New York has gathered in the people of every land, until her American spirit, and the pride of a few in her unique history, cannot be asserted. It is left, therefore, to Philadelphia, and Boston in a lesser degree, to celebrate, from time to time, events in which every American feels a just pride. Besides, its "social leaders" do not feel it necessary to leave town whenever a historical celebration is to take place. Consequently it does these things well. For this reason, we say, Philadelphia deserves to be congratulated.

MAYOR HEWITT made a mistake in proposing that two regiments should use the same armory. Colonel George D. Scott, of the Eighth Regiment, very properly, in an interview with a New York *Herald* reporter, took the ground that armories should be located in different parts of the city, "both for purposes of safety and for convenience in recruiting."

THE Trustees of the Brooklyn Bridge have received from Charles E. Emery, C. E., detailed plans for the alterations in the Bridge terminal. These are modified from original general plans presented by Mr. Emery some months ago, and the Trustees have appointed Mr. F. K. Hain, General Manager of the New York Elevated Railroads, Colonel Julius W. Adams, C. E., and an expert from the Pennsylvania Railroad to consider and report upon them.

OUR SPECIAL ILLUSTRATION.

HOTEL D'ALMY, BLOIS, FRANCE.

OUR VIGNETTE ILLUSTRATION.

OUR vignette illustration shows a club-house at Glen Ridge, N. J. It is built of wood, covered with shingles. All of the rooms, except those of the care-takers, are finished in hard wood. The billiard-room has paneled wainscot eight feet high and barrel-vaulted. Cost, \$8,000. The architect was William Convers Hazlett, of 151 Broadway, New York.

PARIS ORDINANCE CONCERNING THEATRES.

FROM the Police Ordinance concerning theatres, we quote the following :

ARTICLE 4. A theatre comprises :

First—The auditorium and its approaches.

Second—The stage, with its basement and its flies.

Third—The actors' rooms and the offices of the management.

ART. 5. The theatre must be isolated or back to back with another building. In case of isolation there must be left upon the sides which are not upon public streets a space or an alleyway of no more than three metres in width if the neighboring buildings have no windows opening on the said space. But if such is not the case the width will be required to be greater according to the importance and the character of the building. Where a theatre is back to back with another building a brick wall of at least 0m. 25 thickness must be built to protect the party wall.

ART. 6. No door of communication can exist between neighboring properties and the alleyway in the case of an isolated theatre, nor with the interior of any part of the theatre whatsoever where the buildings are back to back.

ART. 7. The three parts of the theatre must be separated by large masonry walls entirely constructed of and covered with incombustible materials. The auditorium and the offices of the management should have distinct exits.

ART. 8. The ceilings and the dome of the auditorium must be built of iron pugged with masonry. Nothing can be put upon the ceilings without the consent of the authorities.

ART. 9. The great wall of the stage front can only be pierced by :

First—The stage opening, which shall be closed by a rolling curtain of iron composed of meshes not more than 0m. 03 in size. The curtain shall be held up by combustible cords. Counter weights hung by metal cables should moderate the quickness of its descent.

Second—The passages required for the relief service, whose position shall be designated by the Commission of the Theatres and which shall be closed by iron doors, a key for which shall be given to the Commissary of Police and another to the members of the fire department. A third key shall be placed on the stage side, near the doors, in a box inclosed by a fixed pane of glass with an explanatory inscription.

ART. 10. The decorations set upon the higher parts of the opening of the stage front ought always to be incombustible, as well as the curtains inclosing the scene.

ART. 11. All cloth used in decoration should adhere closely to the surface which it covers, and particularly to that of the ceiling of the auditorium. The space along this ceiling ought to be entirely empty, nothing being placed there except the apparatus necessary for the management of the chandelier.

ART. 12. The chandelier shall be held up by an iron brace, and managed by a wheel worked by pedals. Its falling shall be moderated by counter-weights, and it shall be hung by two metal cables, each having the same strength to resist a fracture, calculated upon the whole weight of the apparatus.

A metallic netting, with meshes of sufficient strength, shall protect the audience from the possible fall of glass or crystals.

ART. 13. The great rear stage-wall and the side-walls shall show a uniform surface, with no part setting back from its face line or from the perpendicular. These walls shall be pierced only by the openings necessary for the passage of the actors. These openings shall be fitted with iron doors swinging in such a way as to be constantly shut.

In every case where these walls give upon the isolating courts, there shall be set up, at the height of each service-bridge, an exterior balcony, with hand-rail and a fixed iron ladder for the passage of firemen.

In the other case, the roofs of the adjoining structures belonging to the theatre shall be built in such wise that a balcony of safety can be placed under the same conditions.

The passages of access from balconies of safety shall be furnished with iron doors closed only by a latch and opening both ways.

ART. 14. The lobby for the prompter and that for the musicians, formed either by a brick wall or by incombustible partitions, shall be plastered, tiled, slated, or cemented.

ART. 15. No boxes can be placed on the stage without the consent of the Commission of Theatres.

ART. 16. All the scenery shall be made unflammable by means of some preparation for that purpose.

Before being put in use, they shall be tested for their unflammability before the Commission of Theatres, or before one of its members delegated for that purpose.

These tests shall be renewed at least every six months, and they shall be accepted each time by the fixing of a seal at different points.

ART. 17. The doors of the actors' dressing-rooms, of lobbies, as well as the offices of the management, shall be furnished with a grating set in such a way as to facilitate the inspection by the firemen during the rounds required by law.

If these places are lined with lockers the trims of lockers shall be set close upon the floors.

ART. 18. The walls can be decorated with paper glued on, or with tapestry stuffs closely holding to the surface. Cloak-pegs, curtains, and portieres shall be fixed 0m. 70 at least from the vertical plane in which are the gas-jets.

ART. 19. No workshop or storeroom whatever can be placed in the parts of the theatre constituting the auditorium, the stage, and their dependencies.

They cannot be placed in the other division of the theatre without special permission from the authorities.

ART. 20. The storage-room for scenery and properties should be established outside the precincts of the theatre. Only such scenery and properties as are necessary for the running of the plays can be kept within the theatre. The place of storage should be separated from the rest of the structure by a thick masonry wall with iron doors.

ART. 21. No laboratory or storage place for any explosives whatever can be in the theatre.

ART. 22. All the staircases, those that serve the actors' dressing-rooms and the offices of the management, as well as those intended for the public, shall be, besides being dressed with stone, made in such a manner that the steps may be pugged full of masonry held in place by iron braces; the treads only of the steps can be of wood. The staircases intended for the public should be always straight.

ART. 23. The width of staircases for the public and the landings of same shall not be less than 1m. 50 in width.

Starting from the highest story this width shall be increased at each run proportionately to the number of persons who would use it at the time of going out, if the builders do not choose the better plan of giving the staircase throughout its full height the width of the run from the first floor to the ground floor.

ART. 24. The landings of staircases intended for the public cannot be furnished with gates except by the special permission of the authorities.

ART. 25. There should be at least two staircases especially intended for the public and independent of each other. These staircases should serve each story and give exit at the front of the building.

ART. 26. The width of the corridors of exit, and that of the doors leading out, whether of the lobbies of the auditorium to the vestibule, or from the vestibule out, shall be proportional to the size of the theatre.

ART. 27. The total width of openings communicating with the lobby to the vestibule of exit shall never be less than 6 metres for theatres having 1,000 seats or under. The opening of the vestibule on the outside shall satisfy the same condition; if it is divided into several doors, separated by piers, the number cannot be less than 3, and each ought to be at least 2m. 50 in width.

The doors connecting from the vestibule to the cafés, lobbies or adjoining apartments having exit outside will not be counted in the reckoning of these openings.

ART. 28. When the auditorium has more than 1,000 seats, these openings should have the regulation width increased by 0m. 60 for each 100 seats.

ART. 29. The auditorium shall be circumscribed at each story by a lobby of a uniform width, the minimum of which shall be 2m. 50.

ART. 30. The doors opening from the auditorium into this lobby shall be so hinged that they swing fully back upon the exterior facing of the partition and in the direction of the places of exit. The less important doors of the ground floor should swing out from the auditorium to the vestibule.

ART. 31. All the doors opening on the outer walls ought to remain open during the whole of the performance. They can be furnished with vestibules of light construction.

ART. 32. These screens should have their openings at the side, always flap doors, and together represent the same width as the opening stopped by the vestibule. The front of these vestibules shall be pierced by a door in two flaps, each having the same total width and which shall never be closed by lock and key.

ART. 33. All the seats placed in the pit and those of the "amphitheatre" shall be served by two lateral passages, having a minimum width of one metre at least; they shall be divided in the middle by a passage of 1m. 30 leading out to the exit lobby. Together the doors of communication of the seats of the ground floor to the lobby which surrounds the auditorium should have, at least, a total width of six metres. These doors should be placed as near as possible to the outer vestibule.

ART. 34. The rows of chairs, stalls, or benches shall be spaced 0m. 50 from the seat to the back in front. The same distance shall be kept between the benches. The seats of chairs and stalls ought to fold back against back.

ART. 35. No part of the theatre can be heated by any means but registers, the furnace for which shall be in the basement.

The hot-air pipes shall be made of earthenware, with shells 0m. 0.6 thick.

ART. 36. The registers placed on the stage shall be put up 0m. 30 above the floor, and shall be surrounded by metal grilles set 0m. 30 from their outside surface. The register openings placed in the other parts of the theatre shall be set 0m. 16 from all wood-work, such as floors, plinths, wainscots, etc.

ART. 37. The auditorium should be comfortably ventilated by means of appliances which shall be submitted to the approval of the Commission of Theatres.

ART. 38. If gas is used for lighting, there shall be a tell-tale for each part of the theatre.

Pipes more than 0m. 10 in diameter shall be of iron.

ART. 39. If the theatre is lighted by electricity and steam-engines used for this purpose, the engines should be placed outside of the building, or at least be set after a manner especially permitted after consultation with the Commission of Theatres.

The wires should be isolated by a gutta-percha covering and set, throughout their whole run, in an incombustible conduit.

The lighting apparatus should be so arranged as to prevent the dropping of burning carbon.

ART. 40. The use of gasoline, of mineral oils, of hydrocarbons, etc., is absolutely forbidden.

ART. 41. Oil-lamps, furnished with glass shades, and kept lighted from the beginning to the end of the performance, shall be placed in sufficient number in all places where there are openings to prevent total darkness in case of the total extinction of gas or electric light.

The tools, wicks and rags for these lamps shall be enclosed in a metal box.

ART. 42. The stage-lights shall be surrounded by a netting sufficiently away from the fire to prevent the contact of any flying object.

ART. 43. The brackets for gas and stage lights shall be placed in the same vertical plane to prevent any contact with the feeding pipe.

ART. 44. The stage-lights must be hung by three wires at least.

The feeding-pipe for the stage-lights shall be always held up to a height above the highest frame by a proper appliance.

ART. 45. The stage-lights shall always be worked vertically; they can be only lighted in the presence of firemen who are to fix the height at which the lights can be withdrawn.

The calcium-light shall be protected by a wire netting and mounted upon a secure standard.

ART. 46. The lights at the stage front shall be fitted with reserved flames. The footlights shall be furnished with wire nettings of tight mesh forming brackets above the jets.

ART. 47. The movable lights shall be protected as high as a man by netting of tight mesh, and the upper part of said lights shall be crowned by a hood of proper size.

ART. 48. The dressing-rooms and the lobbies for the actors, lighted by gas, shall have jets without elbows; the jets shall be covered by glass globes or with wire netting. The apparatus for movable lighting is forbidden in this part of the theatre.

ART. 49. The passages and the staircases shall be lighted by fixed glazed lights and furnished with wire shades.

For direct means of protection against fires, the authorities demand that there shall be in each theatre a hydrant with sufficient pressure to throw to the highest parts; that there shall be ample reservoirs of water in connection with these hydrants; that there shall be fire-pumps set on the ground-floor and in the basements; that fire-escapes shall be set upon all court and exterior walls; that there shall be telegraphic communication with the nearest fire-engine house.

In regard to offices in connection with the theatres, the regulations require that there should be an office for the police, for the physician, a guard-room for the service-guard, a station for firemen near the wings. No smoking-room shall be provided in and no shops placed under the theatres without the approval of the authorities.

Sufficient sanitary accommodations to be approved by the authorities must be provided.

No booths can be set up in the theatres except for the doorkeeper and the ticket-officer.

The Commission of Theatres is composed as follows : The Secretary of the Prefecture of Police, who is President of the Commission, the Chief of the Cabinet, the Chief of Municipal Police, the Chief of the Theatre Department of the Police Service, the Chief Chemist of the Prefecture of Police, the Colonel of the Fire Department, the Chief Engineer of the Fire Department, the Chief Architect of the Prefecture of Police, the official architect of the district, the Commissary of Police of that division of the city, and the Peace-Officer of the district.

A sub-commission composed of certain members of the above commission shall visit each theatre at certain times, and the members of the commission and other authorities are sent at any time to give such supervision as may be thought necessary.

A Commissary of Police is stationed at all theatres during the performance with a squad of police proportioned to the size of the theatre.

The firemen are to be constantly in attendance.

There must be watchmen-indicators and electric-bells indicating the different stations.

Each theatre must have a corps of physicians, proportionate to the size of the theatre, one of whom must be

constantly in attendance during the performances. In the physician's office must be placed an ambulance call.

Other regulations are made which we think unnecessary to quote.

In 1882 the Theatre de l'Opéra Comique was reported by the Chief of the Fire Department as having the stage in a very dangerous condition on account of the large amount of scenery stored therein, and the close proximity of the storage-house for scenery in the Place Lourvis. He recommended that a special fire-proof building be built to receive scenery, etc., not in use. Other complaints were made in 1886 to the Government of the inadequate means of exit for actors and others employed in the theatre, of the storage of scenery in the basement.

On May 12, 1887, an attempt was made to get an appropriation to make the needed improvements, which was not adopted by the Government. Thirteen days after came the catastrophe.

The fire caught high up upon the scenery; the doors about the stage, which should have been kept closed in accordance with the regulations, were open, increasing the draught; the fire spread rapidly, and although the firemen were promptly at work they could not get it under control.

The man who was in charge of the iron curtain was not at his post, and the point where it was worked was high up in the flies.

Contrary to the regulations, the curtain was hung with wire ropes and it remained in place, and the smoke filled the auditorium; the gases of combustion put out the oil-lamps as well as the gas. The gas went out. The outside doors on the Rue Fasert were locked contrary to the regulations, and in the darkness the keys in the glass cases were not seen; certain staircases were not indicated so as to be known to the public.

Only two narrow staircases served the actors' dressing-rooms; luckily the fire did not occur during an intermission, when these rooms would have been occupied, or but few would have been saved.

The story of this fire is almost precisely the same as that of the Ring Theatre at Vienna.

DOWNFALL OF THE SUSPENSION BRIDGE OVER THE OSTRAWITZA.

FROM *Le Genie Civil* we get the following data regarding the destruction of the suspension bridge over the Ostrawitza, which united the part of the city of Ostraw in Moravia to that portion situated in Silesia, and gave way recently under the weight of half a score of persons, a detachment of cavalry of sixteen men, and two carriages which were crossing it. Men, horses, and carriages were thrown into the river. Many were killed by drowning or crushing under the ruins, and others were badly injured. The construction of this bridge was begun in 1846, under Engineer Tannebauer, but was interrupted during five years on account of violent floods in the Ostrawitza, which caused terrible inundations, so that the work could not be resumed

FIG. 1—GENERAL VIEW OF THE BRIDGE AFTER IT FELL.

until 1851. The bridge measured 92 metres long, 7.09 metres wide, and had a clear span of 66 metres. The floor was supported on each side by means of two chains placed side by side, each chain composed of 6 bars of iron 13 millimetres thick and 101 millimetres broad. The break occurred at one of the ends in the chamber in the anchorage masonry through which the chains passed, as shown in Fig. 2. The free end of the broken chains remained suspended from the tower, while the central span, or that portion which supported the floor, fell into the river as shown in Fig. 3.

At the point of rupture of the chain there remained eleven bars of iron; the twelfth, which was missing, was found in the chamber completely rusted, broken, and covered with dust, which showed plainly that for a long time before this, that bar, by reason of its bad condition, had become loosened from the chain. None of the broken bars showed a sound section of more than about 3 millimetres thick and 75 millimetres in breadth. This thin section was all that remained of the bars of the chain; the remaining portion of the section was completely rusted and torn or wrenched.

At the time of the bridge falling the load exceeded but little 13,000 kilogrammes, which represents about 200 kilogrammes per metre of length. No reason can be given why such a comparatively small load could cause this downfall, when but a short time before more than 300 persons were known to be on the bridge at one time. It is probable, then, that this was caused, as has been the case before (notably at the time of the legendary catastrophe of the bridge of Angero), by the regular marching, in time, of the cavalry crossing the bridge. It seems strange that this bridge had stood so long and had not failed even by its own weight. An approximate estimate of the tension of the chains gives substantially the following results: The weight of the chains, of which the sections combined measure $24 \times 13 \times 101 = 31,512$ square millimetres, becomes, by taking count of pins and eye-bar heads, about 270 kilogrammes per lineal metre. The weight of the floor-planks and joists, suspension rods, etc., may be taken at 1,500 kilogrammes per metre, making together 1,770 kilogrammes. If to this be added the 200 kilogrammes calculated as the moving load causing the downfall, we get 1,970 kilogrammes per metre as the total load.

FIG. 2.—Showing the point of rupture of the chains at the anchorage.
FIG. 3.—Showing the position of the chains at the tower after the rupture.
FIG. 4.—Showing mode of attaching chains at the anchorage.

As the deflection of the chains in the centre span was 4.90 m. in round numbers, the horizontal tension due to the weight of the structure becomes

$$H = \frac{1}{8} \frac{1,770 \times 66^2}{4.90} = 197 \text{ tonnes,}$$

which became at the moment of the accident 219 tonnes. The vertical reaction at the tower due to the load on centre span was $V = \frac{1}{2} \times 1,770 \times 66 = 58,400$ kilogrammes for the permanent load and 65,000 kilogrammes for the total dead and live load. The tension of the chain was $\sqrt{H^2 + V^2} = 205,000$ kilogrammes for the permanent load and 228,000 kilogrammes for the total load. If we suppose that the load was distributed equally upon each one of the chains, and that, as mentioned above, the total sound section of the broken chain $11 \times 3 \text{ m.} \times 75 \text{ m.} = 2,475$ square millimetres, it follows that under the action of the dead weight alone, the tension was

$$\frac{102,500}{2,475} = 41 \text{ kilogrammes per square millimetre,}$$

which at the instant of rupture became

$$\frac{11,400}{2,475} = 46 \text{ kilogrammes per square millimetre.}$$

From this calculation the catastrophe seems perfectly comprehensible. Iron when employed to support an equal tension for a long time ought always to be of the best quality. The rapid deterioration of the iron (which is without precedent, and which during the thirty-five years of the existence of the bridge reduced the section to about one-fourth of what it was originally) proves that the anchorage chambers were badly constructed. All the foul waters of the streets could empty themselves into their interior. Besides which the angle of the parapet wall, which was just at the shore line, was constantly defiled by liquid ammonia, which ran down from the roadway and contributed in a great degree to the injury of the iron. After all this it may seem incredible that at the date of June 25, 1885, the municipality having some doubt of the strength of the bridge asked to have it examined by experts. At the date of July 18, 1885, they received notice that the bridge had been examined in all parts, it had been found in good condition, and was perfectly safe. Now it seems unquestionable that it is this bad condition which caused the accident, and that this condition existed evidently at the time of the inspection.

PAVEMENTS AND STREET RAILROADS.

No. XV.

(Continued from page 434.)

WOOD PAVEMENT IN THE METROPOLIS.*

OBVIOUSLY there are local matters to be considered in connection with wood pavement, for instance, the effect of traffic in a wood-paved street having a sharp gradient. This has not specially come under the author's notice, except at Ludgate Hill, where the blocks laid in 1877 were removed in February, 1884, having been, it is alleged "kicked out" by horses' shoes, and not fairly worn out by vehicles. The inclination of the carriageway of Ludgate Hill is 1 in 25. Similar results are noticeable at the Western approach to Hyde Park Corner, at which place the inclination is 1 in 37. The question of gradient in wood-paved streets is also an important factor in regard to the tractive action of horses and the limit of safety for foothold, and it is regrettable that so little experience thereon is extant. In the city the steepest gradient paved with wood is in Ludgate Hill; in some parts of Piccadilly the inclination is 1 in 25. It might therefore be assumed that, so far as actual safety is concerned, a gradient of 1 in 20 would not be too steep. In Chelsea the main roads are tolerably level, but there is little doubt that the annual wear of the blocks in King's Road (0.144 inch) is greater in consequence of the increased amount of omnibus traffic which has recently taken place, as, owing to a keen competition, omnibuses have been very rapidly driven along the street at times. A considerable amount of light traffic has also seriously tried the wood. In Sloane Street the nature of the traffic calls for no particular observation, and the annual wear of the wood (0.065 inch), together with the traffic-standard wear, gives a result which compares favorably and satisfactorily with any other street in London.

To insure durability, it may briefly be asserted that next to sound construction it is highly important that the number of openings for gas and water services should be limited, and that undue wear and tear can be mitigated by efficient cleansing and sanding. Neglect of the latter not only creates slipperiness, but is followed by permanent injury to the pavement itself.

In support of the author's views, he submits a number of blocks as taken up from various streets in the metropolis. Some are remarkable as specimens of excellent durability, while others exhibit considerable wear, and the very thin ones have created great surprise that a pavement could be held together with blocks so much worn.

Cost of Maintenance.—The author has frequently been asked whether the wood pavement laid in Chelsea has proved economical as compared with macadam, the answer to which may be found in the following statement, which is based upon the assumption that the average life of the wood blocks will be seven years, and which shows that the first cost, repairs, renewals, and cleansing, if spread over a period of twenty years, amounts to 1s. 9d. per square yard, whereas the previous cost of repairing, renewing, and cleansing macadam, but exclusive of first cost, amounted to 2s. 10d. per yard.

Estimated cost of wood pavement per square yard in Chelsea, for a period of twenty years.

	£.	s.	d.
First cost	0	10	6
Repairs	0	0	6
Renewal of blocks every seven years	0	12	8
Interest on loans (at 4 per cent)	0	2	9
	20	1	6
Per annum	0	1	4
Add cleansing and sanding	0	0	5
Total	0	1	9

If the cost be spread over a period of fifteen years only, the figures will be increased to 1s. 8½d. per yard per annum for the wood + 5d. for cleansing, or a total of 2s. 1¾d.

Under the above circumstances it may be fairly assumed that the annual cost of properly constructing, repairing, and renewing wood pavement, exclusive of cleansing, which is subjected to a traffic of 500 to 750 tons per yard width per day of sixteen hours, and leaving it in a thoroughly good condition at the expiration of fifteen years, does not exceed 1s. 9d. per square yard; whereas the average annual cost of repairing and renewing the macadamized carriageways in Sloane Street and King's Road, formerly amounted to 1s. 11d. per square yard, and in Westminster similar repairs cost:

	£.	s.	d.
In Parliament Street	2	10	
" Whitehall	2	10	½
" Victoria Street	2	0	
" Great George Street	1	8	

No doubt many similar instances might be adduced, in support of the assertion that, as a paving material, wood possesses the advantages of economy, independently of the saving in cleansing.

The annual cost per square yard for laying and maintaining wood pavements in various localities, including interest on loans, is given in Table VI. In most instances the actual cost has been supplied, and in the remainder it has been carefully estimated, after making due allowance for efficient and creditable maintenance.

* A paper by George Henry Stayton, Assoc. M. Inst. C. E., and printed in the Minutes of the Proceedings.

VI.—Annual cost of various wood pavements.

System.	Situation.	Traffic weight per yard width per diem in tons.	Annual cost per square yard for first cost, renewals, repairs, and interest on loans (exclusive of cleansing) if spread over a period of 15 years.

The author regrets that he has been unsuccessful in obtaining fuller information as to the cost per square yard relatively to the traffic weight per yard width, but such information as he has obtained he has classified in the following table, and from which certain deductions are drawn. Until local authorities, or those persons directly interested in the question, adopt measures for ascertaining the latter, a considerable amount of theory must necessarily be exercised in deciding the question of cost according to the weight of traffic.

SYSTEM.	DAILY TRAFFIC WEIGHT PER YARD WIDTH OF PAVEMENT.				
	400 tons.	500 tons.	750 tons.	1,000 tons.	1,250 tons.

Improved.
Asphaltic.
Lloyd's.

The figures undoubtedly give the plain system of pavement the highest position in an economical point of view, and show the comparative cost of other systems in a manner not hitherto attainable.

It is apparent that as the minimum net cost of a soundly constructed and properly maintained wood pavement amounts to 1s. 9d. per square yard for a traffic of 500, and not exceeding 750, tons per yard width, the absurdity of some of the maintenance contracts which have been entered into is remarkable. On the other hand, a good bargain was made by the Improved Wood Pavement Co. in 1876, when they undertook to lay and maintain a large area in Piccadilly, also upward of 2,000 square yards in King's Road, upon the "deferred payment" system, the rate for Piccadilly being 3s. per square yard per annum for a period of fifteen years. The result will consequently be that no less than 45s. per square yard will eventually be paid for an expenditure which in all probability will not greatly exceed 30s. In justice to the authorities, who entered into so costly a contract, it should be stated that in the year 1876 the modern system of wood pavement was in its infancy, and that public bodies were somewhat timid in incurring large outlays thereon; and as the contract stipulated that payment would cease immediately the contractors failed to efficiently maintain the pavement, it was considered that the risk would be small, as a proportionate amount only would have been paid.

Much trouble has been caused by public boards accepting low tenders for first cost, and ridiculously low terms for continuous maintenance, and it has been truly stated on a former occasion by Mr. Burt, that some persons "were running a race to see which could get ruined the fastest." This prophecy has been literally fulfilled, but, unfortunately, as in the case of asphalt and other systems of pavement when improperly undertaken, the consequences had seriously damaged the reputation of wood pavement. Considering that persons enter into contracts to efficiently maintain large areas of pavements with a daily traffic of 600 or 700 tons per yard width, for a period

of fifteen years, for the sum of 9s. per yard, whereas the net cost in all probability will amount to 13s., it is obvious that either the pavements will be insufficiently repaired or renewed, and the reputation of wood injured, or that "a day of reckoning" must come. With the experience already gained, it cannot be too strongly urged that public authorities should look ahead, and not accept a tender merely because it happens to be the lowest. Another matter ought perhaps to be mentioned, although, perhaps, a somewhat invidious one—namely, that ample and competent supervision should be provided, so that every detail in the execution of the works, especially the rejection of unsound blocks, may receive attention. The operation of inspecting every block is undoubtedly tedious; for example, in the Chelsea works, where the timber supplied was of fair quality, it was found necessary to separately sort out, reject, and mark about one block in twenty, the rejections being 96,000 out of a total delivery of nearly 2,000,000; and there is little doubt that, owing to the hurry of the work, many blocks were laid which escaped rejection, but assuredly these will be the first to fail. In works of considerable extent it would undoubtedly be a prudent expenditure to employ a competent inspector to look after the blocks alone.

To sum up, the author ventures to assert that a properly constructed and kept wood pavement meets with favor. He has personally ascertained that shopkeepers and residents like it, in consequence of the absence of noise, and the absence of the inconvenience usually experienced by the frequent closing of the carriageway for repairs, as in the case of macadam; that cabmen give it their unqualified approval; and that the Managing Director of the London General Omnibus Company prefers it, if properly kept, to either granite, asphalt, or macadam. Of course, exceptions have to be made in this as in all other cases, but the public generally appear to be satisfied with it. There are sections of the community, however who do not view it with favor, especially carriage-builders, wheelwrights, saddlers, and granite merchants; but their disapproval will be readily understood. The improved condition of the carriageways of some of the best thoroughfares has also created a favorable impression upon strangers which has not been lost, inasmuch as deputations have inspected the various systems and made numerous inquiries into their respective merits, not only on the part of the municipalities of the principal towns in Great Britain, but from France, Germany, and other countries. At the present time a large amount of wood pavement is being laid in Paris and Berlin by the Improved Wood Pavement Company.

The author has described somewhat fully the details of what may be considered to be mere ordinary matters, but as the success or failure of wood pavement mainly depends upon a careful consideration of apparent trifles, he trusts that he may be pardoned for having taken this course. He is of opinion that local authorities should invariably adopt measures for ascertaining the traffic-weight per yard width in a street before deciding to lay down wood pavement, as such information might prevent contractors from submitting a maintenance-tender regardless of the duty the pavement has to perform, and that complete records of annual cost and wear should be kept. He again ventures to remark that it cannot be too strongly urged that the greatest discretion should be exercised in the acceptance of tenders for construction and maintenance, and that no reasonable expense should be spared in providing ample and competent supervision. Under these circumstances he is of opinion that a close-jointed plain system of pavement, judiciously and faithfully carried out, and improved upon from time to time, will give good economic results, as well as insure a sound and suitable carriageway pavement.

Lastly, the author submits:

- (1.) That where the ascertained annual cost of maintaining and cleansing a macadamized carriageway exceeds 2s. 2d. per square yard, or where the traffic is so considerable that a quieter and cleaner pavement is deemed essential, the substitution of wood is desirable.
- (2.) That experience has proved wood pavement to be an economical and a convenient carriageway pavement for the streets of the metropolis.
- (3.) That, notwithstanding many former instances of failure, the modern system has achieved a fair amount of success, and there is no apparent reason why its use should not be extended.

(TO BE CONTINUED.)

WORK OF MISSISSIPPI RIVER COMMISSION.

FROM recent reports of the Mississippi River Commission the evil effects of the attempt by Congress to legislate on purely technical matters becomes apparent. The act of August 5, 1886, provides "That no works of bank protection or revetment shall be executed in said reaches or elsewhere until after it shall be found that the completion of the permeable contracting works and uniform width of the high-water channel will not secure the desired stability of the river banks."

Quoting this, the Commission proceed to remark that the "limitation is based, it is believed, on the theory that a river, if once regulated, will not scour its natural banks. The Commission is somewhat familiar with the opinions and writings of hydraulic engineers, and, so far as it is advised, this theory is totally unrecognized by any authoritative writer on hydraulics. It is universally recognized

by such writers that in general when a large obstruction is placed on one bank of a river a corresponding wearing away of the opposite bank occurs in consequence.

"There is no evidence that a regulated river will not cave its banks, and in most cases it is impossible to build permeable contracting works or secure any narrowing of the channel by them without holding the banks in their immediate neighborhood while the work is going on; the unprotected banks would recede while the contracting works were being built.

"These general views are fully confirmed by the experience of the Commission on the Mississippi river.

"The contraction works at Gold Dust, Plum Point, Duncansby, and Baleshed have been followed by caving on the opposite bank, whose immediate result is, by again enlarging the cross-section of the river, to destroy any beneficial results the contraction works might otherwise produce.

"That such works may secure any valuable permanent contraction, the opposite bank must in general be held by protection works.

"In the opinion of the Commission the idea that the Mississippi River can be permanently improved by contraction works alone is purely visionary and theoretical, contradicted by experience and not supported by any good authority. To adopt such a system is, in the opinion of the Commission, to waste public money. Holding these views, the Commission, as engineers, cannot recommend to Congress so futile an undertaking.

"In the work which has been done in the Plum Point and Lake Providence reaches, the plan which has been so frequently and explicitly recommended by the Commission in previous reports, and which embraces the combination of permeable contracting works and bank protection as means of narrowing and deepening the channel, has been applied."

Notwithstanding the difficulties of great floods, and a failure of appropriations at critical periods, a navigable channel has been maintained in the lowest water, and the Commission say:

"Before these works were begun these reaches were the worst places on the river. It was for that reason that their improvement was undertaken first in order. They are now good.

"These successful and gratifying results have been obtained by the combination of permeable contracting works and bank protection, each supplementing and aiding the other, and, in the opinion of the Commission, could not have been obtained by permeable contracting works alone."

The Commission also call attention to the serious deterioration going on at the works for lack of needed appropriations.

The report is signed by all, but General Gillmore makes the following reservation:

"I concur very generally with the views expressed in the foregoing letter, and have accordingly signed it as president of the Commission, with the following reservation on the subject of bank protection: The revetment of a caving bank with mattresses or other similar device is perhaps the quickest way to afford protection, for the reason that it interposes a covering capable of resisting the wearing and undermining action of impinging water. But the most complete and efficacious method requires that the current be turned away from the threatened bank. This can best be done usually by permeable dikes placed above the point in danger and requiring protection, having their lengths severally adjusted to the object in view."

Captain Thomas Turtle, of U. S. Engineers, in transmitting maps of changes which have occurred in connection with the work accomplished, makes the general remark:

"So far as the construction of dikes relates to the caving of banks, those so far built have only initiated such caving or accelerated it." (Italics ours.)

Assistant Engineer J. S. Ockerson, in transmitting the maps, says of one section (in proof of the Commission's position): "Fletcher's has been partially revetted, and the greater portion of the bank thus protected has resisted the encroachment of the waters which have cut into the unprotected portions some 400 feet during the past two years."

The caving caused by the Gold Dust dikes he places at 600 feet per annum, as against 100 feet before they were built.

At one bend in the Lake Providence reach, the caving in six years has been 3,000 feet, and at another bend 2,000 feet in two years.

The citizens of the United States as a whole are willing that those who have been educated for it shall carry through the great work of regulating and controlling this mighty river. Having chosen a Commission, fair play demands that they be unhampered by the petty restrictions as to methods which a few cranks have succeeded in attaching to the appropriations. It is but human that some mistakes will be made, but the Commission are not men to persist in a mistake when it is once clearly shown by experience to be such; and the mistakes made will but prove to show them the way to right relations of the many problems presented. It seems hopeless to expect that Congress will ever learn this very plain lesson.

SOME DETAILS OF WATER-WORKS CONSTRUCTION.

By WILLIAM R. BILLINGS, C. E.,
Superintendent of Water-Works, Taunton, Mass.

[SOME questions addressed by persons in the employ of new water-works indicated that a short series of practical articles on the details of constructing a water-works plant, included in which would be the laying of pipes, setting hydrants, laying services, etc., would be of value if prepared by a gentleman of experience. We therefore induced Mr. W. R. Billings, the Superintendent of the Water-Works at Taunton, Mass., to prepare them. The illustrations we shall give are from sketches made by Mr. Billings.—Ed.]

The Introductory Chapter will deal with—
THE DISTRIBUTING SYSTEM.

(a) Main pipes.

Materials.—Cast Iron, Wrought Iron and Cement, Wood, Clay.

List of Tools.—Illustrated. (7 sketches.)

Transportation.—Unloading, carting.

Trenching.—Engineering or none; Length and depth of sections; Foreman; Bracing; Bell holes; Tunneling.

Pipe-Laying.—Derrick gang; Quicksand; 3 pieces at once.

Joint Making.—Yarn; Lead; Fuel; Roll or Joiner; How many joints in ten hours; Depth of lead; Shape of bell; Placing hydrants and gates; Back-filling; Filling new pipes; Air cocks; Cleaning up.

(b) Service pipe.

Materials.—Tapping; Cup joints; Tools; Cocks; Boxes; Setting meters; Support for meters.

No. 1.

In the series of papers upon Some Details of Water-Works Construction, of which this is the first, it will be the writer's endeavor to be brief and practical.

He assumes that those for whom these papers will have the most interest have had little or no experience in actual construction, and desire information and suggestion upon the simplest details.

MAIN PIPES.

Materials.—Cast iron, wrought iron with cement or with a protecting coating by some special process, wood, and steel are the materials used in making pipes for the distributing systems of town and city water-supplies.

Salt-glazed vitrified clay pipes have been used by Mr. Stephen E. Babcock, C. E., of Little Falls, N. Y., in that village, and also at Amsterdam and Johnstown in the same State, for conduits in gravity systems. At Little Falls the conduit is over 30,000 feet in length and is mainly of 18 and 20 inch pipe. The low first cost of clay pipe would certainly entitle its claims to careful investigation in planning a low-pressure gravity system of supply. Mr. Babcock has prepared a very elaborate set of specifications for furnishing and laying this pipe, which would be of value to any one who wished to use it.

The writer frankly acknowledges a preference for cast-iron pipe for all but special cases. He is not unmindful of the fact that the town of Plymouth, Mass., after an experience of thirty years is this summer (1887), extending its distributing system by adding 20,000 feet of 4 to 16 inch cement-lined wrought-iron pipe; nor that the town of Dedham, Mass., has had no reason thus far to regret that its water-mains are of this material. Without going further, the cities of Fitchburg and Worcester, Mass., seem to offer experience with this sort of pipe to justify the opinion that the chances for poor work and poor material are greater with it than with cast iron, and the advocates of cement-lined pipe admit, I think, that honest and skillful work is indispensable to the success of this method. We must admit that when made and laid upon honor, cement-lined pipe has an advantage over cast iron in not reducing its original diameter by incrustations, nor is the "advantage out" when we reply that the cleaning machine of Mr. Keating or of Mr. Sweeney may be used to restore tuberculated iron pipe to its original diameter, for the application of these machines cannot be effected without expense.

With its acknowledged advantages of strength and ease in laying, cast-iron pipe is heavy and in its larger sizes expensive to handle. This limits the length in which sections of it can be used, and so does not permit of any reduction in the number of joints to the mile.

In the effort to produce something which should be free from these disadvantages of cast-iron pipe, wrought-iron

pipe treated by a protective process is now upon the market, and has been introduced to a limited extent. Of this it is fair to say that it is still on trial, and some time must yet elapse before its durability can be said to be proven.

Of wood, the writer has no knowledge by actual experience, but its use seems to be limited to a small territory in the West.

Unlike cast-iron pipe, which is bought ready for use, cement-lined pipe is put together in part at some convenient yard or shop in the town which is to use it, and its final construction is carried on in the trench where it is to lie.

The foundation of this sort of pipe is a sheet-iron drum nine feet in length, made in three sections in the 16-inch and larger sizes, and in single sheets in the 4 to 14-inch diameters.

The thickness of metal varies with the sizes; for example we may use

For 4-inch pipe, metal of at Birmingham Gauge,			
" 6 "	" 19 "	" "	" "
" 10 "	" 17 "	" "	" "
" 12 "	" 15 "	" "	" "
" 14 "	" 14 "	" "	" "
" 16 "	" 14 "	" "	" "

with double-riveted seams, using 12-pound rivets for 16, 14 and 12 inch pipe, 10-pound for 10-inch, 6-pound for 6-inch, and 5-pound for 4-inch pipes.

The first step in the making of this sort of pipe is the putting into these drums a lining $\frac{1}{2}$ to $\frac{3}{4}$ of an inch in thickness of cement mortar mixed sand and cement half and half.

The pipe is placed on end over a hole in a low platform, and a lining cone is let down into it from a crane, a derrick, or a simple windlass, and drops through the hole in the platform just far enough to allow the pipe to be entirely filled at its lower end with the mortar. Enough mortar is then shoveled into the top of the pipe from a high platform to make the lining, and the cone is drawn slowly through. The surplus cement as it falls over the top during the upward movement of the cone is shoveled back into the mixing-box, or into another pipe if there be one at hand ready for lining, but no cement that has once set is fit to be used again. After the cone is drawn the pipe should stand 20 minutes or more before it is moved;

FIG. 1.

it is then taken to the grouting table, the ends scraped, and the whole surface examined for defects. If at any points the cement has settled into wrinkles these should be scraped down, and any holes filled with pure cement.

With platforms and swinging crane arranged to place ten pipes on end at once for lining, eight men can fill 100 14-inch pipes in a day, and three men more can grout and patch them.

The grout can be poured in with a dipper, and then spread by rolling the pipe and applying from each end common dust-brushes fastened to long handles.

Before applying the grout the lining is brushed with water, using the long-handled brushes.

The lining cones are made either of cast-iron or of sheet-metal, but if the latter is used they must be filled with cement to give them weight.

LIST OF TOOLS.

Whatever be the material chosen for main pipe, the trenching tools will be the same. In the matter of pipe cutting and jointing, cast iron and wrought iron call for very different treatment and appliances. During days which are too stormy for work and over night, all tools should be securely packed in tool-boxes which may be built according to the following sketch:

FIG. 2.

The same carpenter who makes the boxes can make also a derrick after the sketch given in Fig. 3, which will be found strong enough for pipes weighing a ton and easy to handle as soon as three men get the knack of carrying it.

FIG. 3.

This should be made of straight-grained 4x4 sticks, 14 $\frac{1}{2}$ feet long, held together at the top by a 1-inch bolt. The link of $\frac{3}{8}$ round iron drops one foot, and $\frac{3}{8}$ carriage-bolts should be put through the end of the sticks to keep them from splitting. The large cleat on the right is to be bolted on with two $\frac{3}{8}$ carriage-bolts about 20 inches from the bottom of the leg, and a hard-wood pin driven in about the same distance from the bottom of each of the other legs. For pipes larger than 20 inches a 4-leg derrick with a windlass may be found more convenient.

For 6-inch pipe two 8-inch double blocks will give power enough, but for 16-inch a quadruple and triple block in combination will be needed.

The number of picks and shovels required depends, of course, upon the number of men that are to be employed. One shovel to a man is enough, but if the digging is likely to be hard double the number of picks will not be too many, to allow time for sharpening. A shovel with a welded strap does better work than one in which the strap is riveted, and for anything but scraping up from a platform, a round point is better than a square point.

Provide three, four, or half a dozen steel crowbars 5 $\frac{1}{2}$ to 6 feet long, 2 or 3 sledges weighing say 10, 15, and 20 pounds, and 2 tunneling bars, if the digging will permit of this sort of work. The tunneling bars are easily made by welding on to a piece of 1-inch pipe 8 or 10 feet long a chisel-shaped piece of steel 2 or 3 inches wide.

For ledge-work, drills made of $1\frac{1}{4}$ -inch octagon steel, forged to cut a $1\frac{1}{4}$ -inch hole, with sledges weighing 6 to

CARRYING
STICK-HARD WOOD
4x4

FIG. 4.

8 pounds, and a spoon for scooping out the dust and drillings, will be required.

FIG. 5.

Carrying sticks for lifting 4, 6, and 8 inch pipe, of the shape shown in the sketch Fig. 4, are useful; larger sizes of pipe are handled more easily by rolling.

CUTTING OFF TOOL

FIG. 6.

Skids 6 feet long of 2x4, 4x4, or of 4x6 spruce, according to the weight of the pipe, will be needed to throw across the trench.

When water is not available for back-filling some kind of tamp will be needed, and sketches of two patterns are given herewith, Fig. 5.

If any considerable amount of rock-work is expected, either as ledge or boulders, a second derrick will be needed, with some spare rope and a few pieces of chain.

For cutting cast-iron pipe provide two or three long-handled chisels, such as blacksmiths use for cutting off cold iron, and a pair of light sledges or striking hammers. For cutting wrought-iron pipe boiler makers' chisels and hammers are the proper tools.

FIG. 7.

For making lead joints in cast-iron pipe, yarning and calking tools and short-handled calking hammer. One yarning-iron and four calking tools varying in thickness from $\frac{1}{8}$ to $\frac{3}{8}$ of an inch make a convenient set.

FIG. 8.

A furnace or lead-kettle of the pattern indicated in Fig. 9 is common among water-works' contractors. There should be a second door opening on to the grate at the point on the sketch where the shell is broken away to show the interior.

TRANSPORTATION.

Before the arrival of the pipe arrangements should be made to have men and teams ready to begin work at a few hours' notice; for, as a rule, vessel captains and railroad companies are in a hurry to be rid of their cargoes. Some trustworthy man should be selected to oversee the unloading and keep tally. In cast-iron pipe it is customary to mark the weight of each piece with white paint inside the bell, and if a memorandum is made of the weight of each piece as it leaves the car or vessels, the pipes will be counted and a check on the weight given in the bill of lading will be obtained.

FIG. 9.

The pipes may be piled up on the wharf, or taken directly from the cars on to the drays or low gears that are to cart them. If they are to be put directly upon the drays, little or no blocking will be needed. Strong and careful men with carrying sticks, and some skids in the absence of a derrick, will soon discover the easiest method of handling the pipe and avoiding shocks and blows. If the pipe is coming out of a vessel and is to be piled up on the wharf, 2x4 spruce sticks in market lengths should be placed between the tiers, and strong skids used to roll the pipe from the deck ashore, and blocking be freely applied to prevent bunting, striking, or rolling. In the experience of the writer six active and fearless men easily took 16, 6, and 4-inch pipe from a vessel and piled it securely on a wharf faster than the crew could get it out of the hold with a steam-derrick.

In carting cast-iron pipe convenience and necessity will determine the kind of vehicle to be used, but in carting cement-lined pipe it is well to insist that the wagon shall have springs that the chances for cracking the cement lining may be reduced. The cost of carting must vary so much with circumstances that the writer can do no more than quote some figures from his own experience. Three bids were received in the spring of 1887 for carting an average distance of about two miles over good roads and streets with no steep grades.

680 tons of	125-lb.	16-inch pipe.
100 "	34-lb.	6-inch pipe.
100 "	20-lb.	4-inch pipe.
One of	\$1	per ton gross.
One of	67½	cents per ton gross.
One of	64	cents per ton gross.

At this lowest figure the teamster appears to be satisfied that he is making a fair profit, but his horses and men are working hard for it.

When the town of Middleboro, Mass., constructed its water-works the writer was informed that the carting was done for fifty cents per ton, but the average hauls were short and the roads good.

Considerable judgment is required on the part of the teamsters who deliver the pipe on the street to distribute it so that it will not fall short or run over in laying, so that it will not cause excessive risk to night travelers while it is awaiting the coming of the workmen, so that it will not be in the way of entrances to private estates or of merchants whose teams wish to receive or discharge goods. If circumstances will permit, it will save time for the pipe-layers to have the pipe laid on the street with all the bells pointing one way, and that in the direction of the movement of the gang. This with reference to bell and spigot pipe; with other patterns this condition does not exist.

In directing the teamsters on which side of the street to deliver the pipe, consider on which side of the trench the bulk of the dirt is to be thrown and have the pipe dropped on the side opposite to that, and thus avoid having to lift the pipe over an embankment of loose earth.

(TO BE CONTINUED.)

HOT-WATER HEATING AND FITTING.

BY "THERMUS."

No. XII.

(Continued from page 435.)

HOW TO FIND THE SIZE OF RADIATORS AND COILS AND THE AMOUNT OF WATER THAT SHOULD PASS THROUGH THEM TO GIVE A CERTAIN DUTY.

BEFORE we can proceed to construct and settle the proper sizes for the mains and other pipes of a hot-water apparatus, we have first to determine the size of the radiators or coils that we must use and the quantity and the heat of the water that we must pass through them.

To keep a room warm by artificial means we must add as much heat to its walls and the air enclosed within them, through the medium of our radiators or coils, as is given off from the same room by the glass of its windows, its walls, the air admitted and extracted for ventilation, as well as the cooling done by accidental causes, such as leaky windows, doors, etc. In well-built houses the latter (or accidental factors) become small. In poorly-built ones they are often large, and in frame or wooden houses they are, as a general thing, greater than in brick houses.

To find the amount of radiator necessary to counteract the effect of windows and walls, it is necessary for us to have a good conception of the amount of heat lost through the windows and walls.

Heat from a room or building is lost by radiation, conduction, and convection. From a philosophical point of view, it would be a nice thing for us to know how the sum total of the heat lost is divided between these three methods of transmission, but for our purpose it is only necessary to know what the total amount is and how to find—at least approximately.

At low temperatures, or such as we are likely to have to deal with in hot water and air questions, the heat given off by radiation is less than that given off by convection and other causes. Above 400° Fah. the heat given off by radiation alone becomes greater, but of this we have nothing to do here, though when speaking on the matter of boilers it may be well to say something about it as bearing on their design.

Mr. Thomas Tredgold, C. E., in his work on "Warming and Ventilation," the third edition of which appeared in 1836, after his death, while speaking of the laws of cooling, says: "If the surface giving off heat be different at different times" (having different temperatures only, he undoubtedly means), "the heat given off in a given portion of time will be directly as the excess of temperature of the surface of the body giving off the heat in gaseous media, or in any fluid that is kept in motion."

This would be according to Sir Isaac Newton's theory of the law of cooling, and though later investigators (Petit, Dulong, and others) have demonstrated that this is not absolutely true for even low temperatures, and that at very high temperatures it is erroneous, we have, however, Dalton and Leslie as authority that for differences of temperature between mean temperature (40° Fah.) and 212° Fah. that it is correct enough for any ordinary purpose.

If we accept this, the quantity of heat given off will be directly as the surface and the difference of temperature between it and the media it is giving heat to. This, however, holds true only of surfaces of a like description against which the air can come in contact and rub freely at all points, such as flat windows, flat walls, and flat or vertical radiators; and by flat is meant surfaces that the air can come freely in contact with either as it rises or falls—one whose vertical plane is straight.

We are not far wrong, presumably, when we contrast for comparison the flat surface of a sheet-iron heater with the glass of a window, and taking the difference of temperature into consideration, and it was this W. J. Baldwin did when he adopted the empirical rule given on page 27 of "Steam-Heating for Buildings," which reads: "Divide the difference in temperature between that at which the room is to be kept and the coldest outside atmosphere by the difference between the temperature of the steam-pipes and that at which you wish to keep the room, and the product will be the square feet or fraction thereof of plate or pipe surface

that is the equivalent of each square foot of glass or its equivalent in transmitting power."

According to this rule, if we desire to keep a room at 70° Fah. when it is zero outside, with the temperature of the radiating-surface 212° Fah., we have

$$\frac{\text{Difference between temperature of room and outside temperature, } 70^{\circ} \text{ Fah.}}{\text{Difference between steam-pipes and air of room, } 142^{\circ} \text{ Fah.}} = .493 \text{ sq. ft.}$$

or say one-half a square foot of plate surface.

Now, practice has confirmed this rule as sufficiently near for practical purposes with ordinary good radiators, either in vertical or horizontal coil form, when the length of the vertical pipe or loop is not greater than 30 inches, and with horizontal coils of 1-inch pipe not higher than eight in number.

This, of course, is only an approximate rule for use in direct radiation alone, and, with a liberal addition of from one-quarter to one-half to provide for air admitted accidentally, has always proved sufficient in low-pressure steam-heating.

Of course the value of the walls, in addition to windows, as cooling surface must not be overlooked, and though we have only spoken here of glass, each 7 to 12 square feet of wall-surface, according to its nature, will have a cooling power equal to a square foot of glass, and must be considered the same.

The above is the first and simplest way of finding direct radiation surface for rooms. The example taken, however, was for radiator surface at a temperature of 212°. This is too high a temperature for low pressure for hot-water practice, and the writer, in his own practice in designing for hot-water apparatus, prefers to make his figures on the basis that the water in the coils or heaters of the apparatus has a temperature of 140° Fah., and that the outside temperature is 30°, or just below the freezing-point; then, as the temperature outside goes down, to increase the temperature of the water in the radiators or coils by keeping a stronger fire in the boiler. This gives us:

- (1) Temperature of air of room 70° Fah. — temperature outside 30° Fah. — 40° Fah.
- (2) Temperature of coils or heating surface, 140° Fah. — temperature of air of room, 70° Fah. — 70° Fah.

(3) $\frac{40^{\circ}}{70^{\circ}} = .571$ as the part of a square foot of heating surface at 140° Fah. that will contract the cooling done by one square foot of glass or its equivalent under average circumstances when the outside air is 30° Fah. Of course, to make this a scientific equation, the relative velocities of air-currents would have to be taken into consideration, which would bring wind velocities into the question. That would so complicate matters—and that unnecessarily—that no attempt will be made to do so, as with a hot-water apparatus under increased wind velocities, we have the same means of increasing the efficiency of our surface as we do under a lowering of temperature—namely, the increase of temperature of our water within the limits of our initial coil temperature (say 140° Fah.), and our maximum 212° Fah. or the steam-making point under our atmosphere; which gives us a reasonable range of temperatures that is sufficient to carry us down to a temperature of about 10° below zero outside.

The following columns show approximately the increase of temperature of the surface to the decrease in outside temperatures, increased wind velocities not considered:

Temperature of surface.	Temperature outside.	Ratio of heating surface in sq. ft. to a sq. foot of glass.
140° Fah.	30° Fah.	.571
157° Fah.	20° Fah.	.57
175° Fah.	10° Fah.	.57
192° Fah.	0° Fah.	.57
210° Fah.	10° below.	.57

This gives us the same ratio of hot-water surface as we would have of steam surface figured for the same conditions, and there is no good reason why we should use more surface for hot water than we should for steam, the surfaces having the same temperature. In "Steam-Heating for Buildings" the ratio is .49, because it was assumed the temperature outside was zero Fah. and the temperature of the pipe 212° Fah.; but here the calculations are based on the assumption that the air outside is 10° below zero, so that for low temperatures in the coils the surface may be a little more efficient.

To this ratio of .57 square foot of pipe or plate surface to one of glass or its equivalent of wall surface, from $\frac{1}{4}$ to $\frac{1}{2}$ more should be provided for warming air accidentally admitted and for loss of heat by sources other than the walls and windows, and the addition must depend on the character of the building and the judgment and experience of the designer.

Roughly, then, a building will require a ratio of plate or pipe surface of from .70 to .85 to one of glass at the temperatures given in the first column in the table to maintain them at 70° Fah. by direct radiation when the air outside is of the temperatures given in the second column.

Mr. Thomas Tredgold, early in the present century, considered the question of loss of heat from heated surfaces in a very thorough manner, and later he was followed by Mr. Charles Hood on the same subject, both having the same object in view—namely, to find the value of radiating surfaces for warming buildings.

Mr. Tredgold found that 2.19 pounds of water cooled from 180° to 150° Fah. in a vertical tin cylinder in 46 minutes, the exposed sides of which was 79 square inches, when the temperature of the room was maintained at 55½° Fah. during the trial. This gave a mean difference between the air of the room and the surface of the cylinder of 109.5° Fah.

From this we have 2.19 pounds of water cooled 30° Fah. by $\frac{79}{144}$ of a square foot of surface in 46 minutes of time, which = 65.7 heat-units for the time, or 85.7 heat-units for an hour of time, and 156.21 heat-units as what would be given off by one entire square foot of the same surface (tin cylinder) in an hour of time. This total heat, for a square foot of surface, for an hour of time, then, divided by the mean difference of temperature (109.5° Fah.) between the air and the surface of the cylinder = 1.42 heat-units; the amount given off per square foot of surface per degree difference of temperature.

His second experiment was with a glass cylinder that held 2.125 lbs. of water and had a surface of 71 square inches. It cooled from 180° to 150° Fah. in 31½ minutes in a temperature of 56½° Fah., which, by the same method of reasoning as we used before, gives 2.248 heat-units per hour per square foot of surface per degree (Fah.) difference.

His third experiment was with a sheet-iron cylinder—the surface being that of new sheet-iron unpainted—whose surface was 76.7 square inches, holding 2.14 lbs. of water and cooled from 180° to 150° Fah. in 29 minutes, the temperature of the air of the room being 57° Fah. By the same reasoning and method of calculation used in the foregoing examples we can find that the sheet-iron gave off 2.35 heat-units per hour per square foot of surface per degree difference of temperature.

These cylinders were as nearly alike as they could be obtained in form and size and one cover fitted all. They were suspended by cotton threads, so little or no heat could be lost by conduction or contact, and the sides and bottoms were exposed to the action of the air, etc. The top was covered by about one inch in thickness of alternate folds of cotton and flannel, so that the loss of heat by this direction was very small.

A few days later when the experiments were repeated the iron cylinder had become rusted. This Mr. Tredgold says increased its efficiency in the proportion of 156 and 180; the rusted cylinder having the latter value when the new one had the former. The experiments with the tin are of no value to us except to show that bright surfaces have a less value than dull or slightly roughened ones. Experiments with brass, etc., by other experimenters confirm this. The relative values of glass and iron, however, are of some value to us as showing how nearly they agree: the iron being the better of the two, even when new and bright, and increasing in value as it becomes rusty.

It would be well to remark here that probably when surfaces become dusty, which they will in practical heating, they may deteriorate somewhat, and that it would be well to assume that what they may increase in efficiency by rusting will be offset by accumulations of dust, etc., in most cases.

The form of Mr. Tredgold's cylinders—short, vertical ones—are presumably the best that can be devised for giving off heat. The same cylinders in a horizontal position would probably be found to be a little less efficient, and if they were to be increased in height, say two or three times, though used in a vertical position, it is only reasonable to suppose they would do less duty, for the very simple reason that the air in contact with the upper parts

has been warmed somewhat by the lower part as it passes upward, and, therefore, is not capable of extracting as much heat. The same holds good of horizontal cylinders when placed one above the other; each successive one, counting from the bottom upwards, does less work than the one next below it.

According to the above relative values, therefore, of glass and iron the empirical rule given above for finding heating surfaces by the window area, etc., is not without some scientific pretence, as the loss of heat through the glass of a window can rarely, if at all, be greater than through the iron of the heaters for equal difference in temperatures or for proportional differences.*

(TO BE CONTINUED.)

TO HEAT A CONSERVATORY BY HOT WATER, UTILIZING HOT-AIR FURNACE HEAT.

LA CROSSE, WIS., September 9, 1887.

SIR: I have a customer who wishes me to heat a conservatory with hot-water circulation-pipes, the heat being obtained by a coil around the outside of a Boynton hot-air furnace located in the basement; the conservatory is on the first floor. He also wishes a 50-gallon boiler connected with the circulation-pipe, and also with the hot-water boiler in the kitchen, so that hot water for house use can be drawn from both, thus increasing the amount of hot water that can be drawn at one time.

The kitchen-boiler is about thirty feet away from the conservatory and the furnace is about midway between the two, and in basement below. Kitchen-boiler is supplied from tank in attic. I enclose a sketch of the manner in which I propose to do the work and would like your opinion on it, and also any suggestions in the way of improvement, it being a new field for me. Please let me hear from you soon, and oblige an old subscriber.

Yours truly, W. P. POWERS.

[There appears very little objection to the method you propose and show, and its working depends entirely on the diameters of the pipes and the amount of coil in the water-back. Use not less than a 1-inch pipe in the coil in the conservatory, and if the coil and pipes are over 100 feet long from storage-tank to end and return, make all 1 1/4-

inch pipe, and carefully ream the ends in any case. Instead of taking a single flow-pipe from the head of the storage-tank and dividing or branching it to both kitchen-boiler and coil, it would probably be better to take a branch from the water-back pipe at *a*. This will give you hot water earlier and presumably hotter in the coil, but it has this disadvantage: should the furnace fire get low or go out you would not have the advantage of the circulation that would go on from the storage-tank after the fire went down. The storage-tank and all the pipes, of course, should be well covered to prevent the loss of heat.

As air will accumulate in the coil at the highest point, either a small air-chamber and pet-cock should be applied, or a small pipe run above the house-tank similar to what you show from the kitchen-boiler pipes.]

*I do not draw the same deductions from Mr. Tredgold's experiments that he does himself, and, therefore, did not give his figures here, but substituted my own in the manner recently shown; the summary of the matter being that the heat lost through glass would be 2.248 H. U., when that lost through iron would be 2.35 H. U.

Novelties.

Under this heading we propose to describe and illustrate appliances of probable interest to our several classes of readers. The selection will be made without reference to the wishes of agents or patentees, being governed solely by considerations of novelty, ingenuity, and probable interest to readers, and especially the fact that they have not been elsewhere described. As a rule we shall make no comments, and it is to be distinctly understood that a notice does not imply approval. No charge will be made for these notices, and any offer of pay for their insertion will insure their omission. We shall be glad to have our attention called to novelties suitable for this section.

REDUCING-VALVE.

THE illustration presented herewith is a section of a new and novel form of pressure-reducing valve, the invention of Mr. Richard H. Mather, of Windsor, Conn. There are no levers or diaphragms used in this valve, Mr. Mather having evidently tried in his valve to reduce to the minimum number of parts. The valve is intended for steam or other fluids, but for the purposes of description we will treat it as being used on a steam-pipe.

The device consists of a balanced piston-valve having a hollow top and bottom head connected by a hollow neck. The ends of the piston are closed, but the neck has several large ports located midway between the heads, and numerous small ports are located as near to the bottom of the lower piston-head as possible. To the top of the piston is attached the valve-rod, which passes out through a long sleeve formed on top cover of cylinder, and which fits the rod so nicely as to be steam-tight and yet allow of free longitudinal motion. On the stem near the top is a collar serving a twofold purpose—that of limiting the travel of the valve inwards and also to carry the weights, which are in the form of rings and can be put on or off as required. The outer casing or body of valve is cylindrical in form, being enlarged at the bottom to allow the steam to clear the valve when in the position shown; the upper part being bored true to fit the piston-valve just described.

When in use the valve is connected by the neck shown on the right-hand side of casing to the source of supply, the distributing pipes being attached to the neck on the bottom head. The mode of operation is as follows: When not in use the piston is depressed by the weights to the position shown in the drawing. Steam under pressure being admitted to the cylinder part A, between the two piston-heads, enters the hollow interior of piston by the ports B and escapes by the ports C into the chamber D and thence through the distributing pipes. The chambers above and below the pistons are maintained at a uniform pressure by means of the equalizing-pipe shown on the left side of drawing. It must be observed that the bottom area of piston exceeds the top area of the same by an area equal to a cross-section of the valve-rod; therefore, so long as the pressure in the top and bottom chambers does not rise to such a point that the difference between the aggregate upward pressure upon the bottom of piston and the aggregate downward pressure upon the relatively smaller top of the same is equal to the weight of the piston, valve-rods and weights, the position shown will be maintained; but when the pressure in the chambers rises above the point described, the excessive upward pressure upon the piston raises the same toward the position indicated by the dotted lines, carrying the ports C within the close-fitting portion of the casing and cutting off the steam, hence the pressure on chamber D cannot rise beyond the point described. When the pressure in D again falls below that point the piston is forced down by the action of gravitation, opening the ports and immediately restoring normal pressure from the interior of the pipe. The degree of pressure within the chambers is

by increasing or diminishing the weight on top of valve-rod; the equalizing-pipe is so small that any considerable quantity of steam or other fluid cannot pass suddenly between the top and bottom chambers, and, for this reason, the automatic adjustments described are made by gradual and steady movements.

THE "WAVE" SYPHON WASTE-PREVENTING CISTERN.

THE illustration shows a new form of syphon cistern, the feature of which is the method of starting the syphon. The syphon is of the annular type, surmounted by a fixed bell or cylinder. The inner leg is provided with a collared flange traveling free upon it and acting as a piston or riser.

This flange, piston or riser is actuated by the forked bell-crank lever through the medium of a rod connected with the chain and pull handle. A pull on the chain causes

the flange to rise on the leg and thereby start the flow of the water over the top. It is claimed that the cistern is a perfect waste-preventer, as the inner leg of the syphon rises above the top edge of the cistern and will not therefore afford a waste for the water should the overflow-pipe become stopped.

The manufacturers are Messrs. George Farmiloe & Sons, 34 St. John Street, West Smithfield, London, Eng.

Gas and Electricity.

Illuminating Power of Gas in New York City.

Week ending	New York Gas-Light Company.	Manhattan Gas-Light Company.	Metropolitan Gas-Light Company.	Mutual Gas-Light Company.	Municipal Gas-Light Company.	Kickerbocker Gas-Light Company.	Equitable Gas-Light Company.
September 17.....	19.82	21.09	21.95	27.74	26.92	21.85	28.57

E. G. LOVE, Ph.D., Gas Examiner.

THE Municipal Council of Paris has passed an ordinance that all theatres must substitute electric-light for gas within three months, must enlarge the lobbies and passages in accordance with the regulations of the Prefecture of Police, and put in iron curtains.

ELECTRIC-LIGHT has been introduced with great success in the Vienna Opera House. The generating station is at a considerable distance, and to overcome this difficulty four large storage-batteries have been placed in the vaults of the building, taking off the current at four points, so that at no point need tension or electrical pressure be any higher than that which has been usual in lighting ordinary houses. The same system is to be applied to all the theatres, public buildings, and large palaces in central Vienna.—*The Architect*.

A CHICAGO inventor has taken out a patent for a method of making impervious the joints of the lead pipe of electric cables, and assigned it to the Western Electric Company, same place.

We are of the opinion that a better way to make wiped joints on lead pipe is to use solder of the proper degree of fineness, and to employ a plumber to do the work that knows how to wipe properly. Joints that will withstand 100 pounds of water-pressure can be made this way, and require no "doaping."

NOVEL PIPE-JOINTS OR COUPLINGS FOR NATURAL-GAS.

THE recent interest manifested by many patents issued for joints for cast or wrought iron pipe that will withstand high pressure such as is encountered in the conveyance of natural-gas from the wells, induces us to present,

364,666
Pipe Coupling. John O'Leary, Bayonne, N.J.

364,686
Pipe Joint. John J. Thomas, Pittsburg, Pa.

364,947
Pipe Joint for Gas Mains. Frank Moore, Pittsburg, Pa.

365,068
Coupling for Joining Pipes. Eli E. Hendrick, Carbonate, Pa.

365,387
Pipe Coupling. John S. Klein, Oil City, Pa.

365,425
Pipe Joint. William C. Barclay, Wellsburg, W. Va.

without comment, the following drawings of the inventions, their numbers, and the names of the inventors, as selected from two recent issues of the Official Gazette of the United States Patent Office.

TO PUT DOWN SCREW-PILES.

THE address of Captain K. Korow, 233 Eckford Street, Greenpoint, Brooklyn, N. Y., to put down screw-piles. He has worked under U. S. Engineer officers.

ARCHITECTURAL LEAGUE COMPETITION.

THE Architectural League has instituted an annual competition, open to "any one under the age of twenty-five and resident in the United States." The prizes are to be gold and silver medals, known as the medals of the Architectural League. The drawings will be exhibited at the annual exhibition and judged by a jury appointed for the purpose. The programme will appear in an early issue.

BOSTON SOCIETY CIVIL ENGINEERS.

THE regular monthly meeting of the Boston Society of Civil Engineers was held at the society's room, Wednesday evening, September 21, after an intermission of two months.

Twenty-five members, two visitors present.

Mr. Frank W. Hodgdon read a paper entitled, "A Short Description of the Methods of Filling South Boston Flats."

Mr. Charles W. Folsom made some remarks on a wash-out at Arlington, on the Boston and Lowell Railroad.

NEW ENGLAND WATER-WORKS ASSOCIATION.

THE fall meeting of this society was a genuine outing, and no business was attempted, except the election of four new members.

The party numbering 38, with 13 ladies, left Boston on the morning of the 14th inst., and a few hours later took

the steamer "Mt. Washington" for a delightful sail across the lovely Lake Winnepesaukee—Smile of the Great Spirit, in the Indian tongue. President Darling presided at the brief meeting held in the steamer's cabin, and the following gentlemen were elected members of the association:

Active Resident.—Charles H. Swan, C. E., Boston, Mass.; Sylvanus D. Horton, Secretary, Pawtucket, R. I.; Charles E. Prevel, Superintendent, East Providence, R. I.

Non-Resident Active.—Joseph A. Lockwood, Yonkers, N. Y.

Dinner was served on board and was appreciated, as it deserved to be. A short stay at Centre Harbor and the return sail across the placid lake, beautiful with afternoon shadows from Rattlesnake Island, finished the excursion, and the party rolled into the Boston and Maine station about 8 P. M., well assured that the day had been a pleasant one.

AMERICAN SOCIETY OF CIVIL ENGINEERS.

SECOND fall meeting was held September 21, W. H. Paine, Past Vice-President, in the chair. Written discussions on "Excessive Rainfall" and on the "Kentucky and Indiana Bridge" were presented and read by the Secretary.

Discussion of paper of Captain R. L. Hoxie on "Excessive Rainfall," by S. Whinney. At Somerset, Ky., about noon of August 12, 1886, a sudden downpour of rain occurred, accompanied by sudden shifting winds and lightning. Duration of shower, thirty minutes, with a total rainfall of 1.57 inches. Estimated that three-fourths fell in twenty minutes. At the same place on August 27, 1886, about 3 P. M. the rainfall in forty-five minutes was 1.18 inches, and fully $\frac{8}{10}$ of the amount fell within thirty minutes. During the night of May 7, 1882, a rainstorm occurred in south-eastern Mississippi. A stream called Rocky Creek, two miles south of Ellisville, Jones County, with a drainage area of about fifteen square miles, rose to a flood cross-section of about 4,700 square feet. Its velocity could not have been less than $3\frac{1}{2}$ feet per second, giving a discharge of about 16,500 cubic feet per second. If two-thirds of the water falling reached the creek, the rainfall must have been two and one-half inches per hour. This storm continued for six hours, and the total depth of rainfall, estimated from most reliable data obtainable, was sixteen inches. J. Foster Flagg made a statement of rainfall which occurred on the Caribbee Islands in 1885, which partook, apparently, of the nature of "cloud-bursts," and the extent of this rainfall estimated to be six to eight square miles. But little rain fell during the evening of the night it occurred before 10 or 11 P. M., and before daybreak, 5 A. M., it was all over.

A sugar-tank, thirty inches in depth, was found running over in the morning, and known to have been empty before the storm. The total estimated depth was thirty-six inches. Its destructive effects upon the little town of Basse Terre, the capital of the island, strongly corroborates the estimated rainfall. The town is built on a plain along the shore, having a slight slope upward from the sea, with no semblance of a hill or valley on either side of the town, except in the rear, where Monkey Hill very abruptly rises to an altitude of 1,150 feet. The island has an area of sixty-eight square miles, and only five or six square miles drain in the direction of this town. Notwithstanding the shortness of the street, they were filled in places with a torrent over eight feet deep, and more than two hundred persons were drowned, a large number being carried out to sea. This torrent brought with it a large amount of detritus, and the northern half of a public garden, 450 feet square, was filled with mud to a depth of four or five feet, and water six or eight feet deep. The following morning a woman was dug out of the mud, who had been caught as she was attempting to cross the square, and buried upright as she stood. This square is only 225 feet from open shore, with two streets thirty and thirty-three feet wide leading from it to the shore.

Mr. F. Collingwood contributed the following, prepared from reports of U. S. Signal Service reports, of an exceptionally large rainfall at Alexandria Rapids Parish, La., on June 16, 1886. During this storm the wind changed every forty-five or fifty minutes. The town was eight-tenths flooded, and some portions eight feet deep. The rainfall from 5 P. M., June 15, to 6:40 A. M., June 16, was 11.09 inches; from 6:40 A. M. to 8:45 A. M., 2.16 inches; from 8:45 A. M. to 12:50 P. M., 8.15 inches; total for the nineteen hours and fifty minutes, 21.40 inches.

Discussed also by Messrs. Davis and Andrews.

The next paper was a discussion of Mr. Moulton's paper on the Kentucky and Indiana Bridge, by J. W. Schaub. Oral discussion followed by Mr. Emery Cooper.

Additional subscription to building fund: Mr. F. H. Brendling, \$25.

AMERICAN INSTITUTE OF ARCHITECTS.

WELLES BUILDING, 18 BROADWAY,
NEW YORK, September 22, 1887. }

SIR: At a meeting of the Board of Trustees A. I. A., held yesterday afternoon, the following candidates were elected Fellows—viz:

M. L. Beers, D. H. Burnham, II. L. Gay, H. W. Hill, William Holabird, J. W. Root, S. V. Shipman, J. L. Silsbee, and A. Smith, all of Chicago; and the following were elected Associates:

Otis Dockstader, Elmira, N. Y.; Alfred F. Pashley, Chicago; George W. Bunting, Oscar D. Bohlen, R. P. Daggett, James B. Lizius, J. H. Scharn, Adolph Scherrer, all of Indianapolis, Ind., and Charles P. H. Gilbert, of New York City.

The societies of architects in Washington, D. C., and Indianapolis, Ind., were, on application, admitted as Chapters of the Institute.

The officers and members of the Washington Chapter are as follows:

J. L. Smithmeyer, President; W. M. Poindexter, Vice-President; Glenn Brown, Secretary; C. A. Didden, Treasurer.

Professional Members—J. L. Smithmeyer, F. A. I. A.; John Moser, F. A. I. A.; O. Von Nerta, A. A. I. A.; S. M. Howard, A. A. I. A.; W. M. Poindexter, A. A. I. A.; J. A. Henry Flemmer, J. R. Marshall, C. A. Didden, A. A. I. A.; Glenn Brown, F. A. I. A.; C. H. Reid, T. F. Schneider, A. A. I. A.; Robert Stead, William Kirkus, Jr., Henry H. Law, Paul Schultze, M. Adolph Cluss, F. A. I. A.; Joseph C. Hornblower, J. West Wagner, Will. A. Freret, Edward Clark, H. L. Page, H. H. Kendall.

The secretaries of the A. I. A., the W. A. A., the A. L. N. Y., and of each chapter of the Institute are *ex-officio* corresponding members.

The membership of the Indianapolis Chapter consist of the gentlemen just elected to associateship in the Institute, together with Mr. D. A. Bohlen, F. A. I. A., its President; Mr. Lizius being the Secretary.

Yours truly, A. J. BLOOR, Secretary.

CONCRETE WORK UNDER WATER.

THE *Bulletin de la Ceramique* has called attention to the process employed by M. Houde in concrete work under water. It was desired to make the concrete penetrate between stones driven into the bottom at irregular intervals, it being impossible under these circumstances to use ordinary caissons. A square tube of 16-inch sides of ordinary planks was so arranged that it touched the bottom, while its upper extremity rose about sixty inches above the surface of the water, being transportable along the length of the work. This tube served to convey the concrete to the desired spots. When the tube is being raised care must be taken that the upper surface of the concrete does not descend below the level of the water. Layers of about sixteen inches thickness can be laid without the slightest difficulty by this appliance. The entrance of water and consequent saturation of the concrete at the commencement of the operation can be prevented by the lower orifice of the tube being closed with a board kept in position by cords, the tube being let down in such a manner while being filled, that the surface of the concrete is always above the water-level. When the lower orifice is near the bottom the cords are removed. This system was used with marked success in the construction of the bridge over the Loire on the line from Blois to Romorantin, when each appliance laid about 2,000 cubic feet of concrete per day. —*The Engineer*.

PERSONAL.

LIEUTENANT THOMAS L. CASEY, U. S. Engineers, has been ordered for duty from San Francisco, Cal., to Newport, R. I.

PROFESSOR J. H. VAN AMRINGE, of Columbia College, has the sympathy of a large circle of friends in the affliction he has sustained by the recent drowning of his son, who was a member of the class of '89.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

For works for which proposals are requested see also the "Proposal Column," pages 449-453-455-456.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE SANITARY ENGINEER AND CONSTRUCTION RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

WATER, SEWERAGE, ETC.

FENTONVILLE, MICH.—Water-works will be built here.

WASHINGTON, GHO.—Water-works will be built here, as already reported. Address B. S. Irvin.

WINCHESTER, KY., will build water-works. J. L. Frazier and W. T. Attersall are committee.

SOUTH PITTSBURG, TENN.—In reference to this place, previously reported, a franchise for water-works has been given to Nashville and local parties. James L. Gaines will give further information.

NESS CITY, KAN.—Mr. R. Osborn writes, over date, of September 19: "The Council instructed the City Attorney to draw call for an election to vote bonds for water-works, and nothing was done on the water-works, as the Council had in view a chemical fire-engine, which should have been here before this. If the engine is not satisfactory at the trial, I think they will go ahead with the bond proposition."

TUSCOLA, ILL.—Mr. A. C. Seuss, City Clerk, writes that "the city authorities have given up the water-works improvement, on account of the provision in our State statute, which will allow an indebtedness only of five per cent. of the assessed valuation, and our assessment is only about \$300,000, so that we cannot create an indebtedness sufficient to construct the works."

FENTON, MICH.—Mr. C. L. Corrigan, Town President, informs us that they have not taken any steps as yet, and do not think they will this season, in regard to water-works.

MARINETTE, WIS.—Incorporated is the City Water Company, with a capital stock of \$200,000. The incorporators are C. M. Fairchild, A. C. Brown, and C. R. Johnston.

NEWCASTLE, CAL.—The Bear River Ditch Company has made preparations to supply, within the next two months, the middle, southern and western portions of Placer County with all the water required for irrigation, mining and milling purposes.

SAUGUS, MASS.—Our correspondent writes: "The town of Saugus have contracted with Goodhue & Birnie, of Springfield, Mass., to lay about 7 miles of wrought-iron cement-lined pipe, and will connect with the water system of the city of Lynn, having a contract with that city for supplying water."

LONDON, ONT.—Our correspondent writes: "Application will be made by the Municipal Council of the corporation of the city of London, at the next session of the Legislature of Ontario, for an act to authorize this corporation to give debentures for \$12,000 for extension of our water-works; also to amend the present act to authorize the corporation to compel citizens to pay for water service from the mains adjacent to their properties."

WINCHESTER, KY.—Over date of September 12 our correspondent writes: "W. A. Attersall and J. H. Fryer were appointed Committee of Council to report on advisability, and authorized to visit other towns and report as to different plans, etc."

MANKATO, MINN.—Our correspondent writes: "The city of Mankato is now constructing a reservoir with an elevation of about 230 feet, and connecting the same with 16-inch pipe, water for the same to be forced from flowing wells on a level with the city."

AUGUSTA, GEO.—Our correspondent writes: "We enlarged our water-works here in the early part of 1885. There is no further contemplation of improvement except the usual extension of mains, etc."

WEATHERFORD, TEX.—We have referred previously to proposed water-works here. Address Matt C. Cameron in regard to taking franchise for works. Immediate attention necessary.

ORLAND, CAL.—On September 11, city election, by a considerable majority, organized an irrigation district, and the necessary work will be done.

VICKSBURG, MISS.—S. R. Bullock & Co., of New York, will push the water-works here to completion.

GREELEY, COL., is still discussing water-works. Address the City Clerk.

WATER-WORKS are reported as projected in the following towns: Gaylord, Mich.; Lyons, Ill.; Templeton, Cal.; Norfolk, Neb.; Bellevue, Mich.; Tazewell Court-House, Va.; Worcester, N. Y.; contract let to Francis Leonard; Albany, Geo., by Jeter & Broadman; Salisbury, Md., by J. A. Cloud; Saugus, Mass., by Goodhue & Birnie; Morrisonville, Ill.; Milford, Del.

VALLEY FALLS, KAN.—Mr. H. D. Butts, City Clerk, writes: "We have advertised for bids to put in a system of water-works."

EVANSTON, ILL.—Our correspondent writes as to water-works at North Evanston: "There has been no definite action taken as yet in regard to supplying the northern part of this village (North Evanston) with water. The probabilities are that some action will be taken some time this fall."

AKRON, COL.—Our correspondent writes: "It is understood here that the Lincoln Land Co., headquarters at Lincoln, Neb., have under advisement the scheme of a system of water-works for Akron, but what steps they are taking in the matter we are not permitted to know."

COLUMBIA, MO.—Our correspondent writes: "We have advertised for bids for water-works in our town according to plans and specifications which we have had drawn up by a competent engineer. James C. Orr is City Engineer."

MCKENZIE, TENN.—In reference to reports about water-works here our correspondent writes: "I am sorry to inform you that there is no plan for water-works suggested or thought of in our town at present."

GRAND RAPIDS, MICH.—The Board of Public Works has awarded the contract for the construction of a sewer in Sherman Street to Joel Collins for \$12,800.

GLENS FALLS, N. Y.—A company of Glens Falls and Ticonderoga capitalists have purchased the water-power at Alice Falls, near Ausable Chasm, and will soon erect a large pulp mill and a paper mill. About \$75,000 will be invested in the works.

HINSDALE, ILL.—Incorporated is the Hinsdale Water-Supply Company; E. W. Perry, Eugene E. Crosby, G. W. Hinckley, incorporators.

FORT COLLINS, COL.—A petition signed by the property-owners in the city will be presented to the City Council at its next meeting, asking that immediate action be taken toward supplying a system of drainage and sewerage.

MANITOWOC, WIS.—We recently noted the progress of a movement for water-works here. On the 25th of October Emil Baesch, City Clerk, will open proposals for the work. There will be a stand-pipe (direct pressure), 12.3 miles of pipe (16 to 6-inch), and about 155 hydrants. The population is about 7,000. Bids should state (1) the annual rental for 135 hydrants; (2) charge for additional hydrants, and rates to consumers.

EASTON, MASS.—The construction of water-works is progressing rapidly. The well is sunk to the required depth, the foundation of the stand-pipe nearly all laid, about a mile of pipe is laid and two miles of the trenches are excavated. The contractor will lay a mile of pipe per week.

KAUKAUNA, WIS.—We have previously noted this town. On September 13 a resolution passed City Council authorizing the Water Committee to employ an engineer to prepare plans and specifications for the water-works plant.

TRENTON, N. J.—The Sanitary Committee has filed an estimate for extending the outlet sewer into the channel of the Delaware River. The cost is \$40,000.

OMAHA, NEB.—The Omaha Water-Works Company has bought out both the Stockyards and South Omaha Land Company's water-works plants at South Omaha. The stock yards and land company's system will still be held as only auxiliary to the system-in-chief until the completion of the new works at Florence.

CLARKVILLE, TENN.—It is reported that water-works will be built here.

LONG PINE, NEB.—Bids for constructing water-works on plans by A. A. Richardson, of Lincoln, Neb., consulting engineer, will be opened October 8.

CHICAGO.—Incorporated is the Shone Hydro-Pneumatic Sewerage and Water-Supply Company for executing works on the Shone system; incorporators, Urban H. Broughton, Edwin Notton, Chester B. Davis.

ISHPEMING, MICH.—Much sewer-work, estimated at \$50,000, will be done very soon. Address the City Engineer. The plans have been completed by Chester B. Davis, of Chicago.

SAN FRANCISCO, CAL.—Articles of incorporation of the Indio Land and Water Company have been filed to bore and excavate for water and dispose of the same. The capital is \$1,000,000, and the directors, who all reside in San Francisco, are as follows: Charles N. Shaw, George W. Durbrow, Charles E. Green, M. Hubbard, and Henry Durbrow.

SYCAMORE, ILL.—We have, in previous issues, noted that water-works would be built here. The plans have now been prepared by Chester B. Davis, C. E., of Chicago. The estimated cost is \$30,000.

NEGAUNEE, MICH.—Plans for the sewerage of this place have been prepared by Chester B. Davis, of Chicago.

SOMERVILLE, MASS.—A recommendation that \$20,000 be borrowed for water-works extensions is now considered by City Council.

SARATOGA, N. Y.—Proposals are wanted for furnishing iron water-mains. Address the Water Commissioners.

DECATUR, ALA.—At a meeting of council, September 20, the city and the Decatur Land Company entered into a contract with A. H. Howland and George A. Ellis, to build works with pumping-plant, stand-pipe, 20 miles of pipe and 20 hydrants. This contract abrogates that made last spring with Inman Brothers, of New York City, who are held not to have begun work within the specified time.

NEW ROCHELLE, N. Y.—The New Rochelle trustees have appropriated \$3,000 to defray the expense of preparing plans and specifications for the new \$100,000 sewer they have determined to build.

EASTPORT, ME.—The Selectmen of Eastport have contracted with the Eastport Water Company to provide a water-supply from Boyden Lake at \$4,000 per annum rental.

SAN DIEGO, CAL., wants proposals for the construction, complete, of 135,000 feet of sewer.

ALBANY, N. Y., will set 175 additional hydrants. Address the Fire Commissioners.

ALLENSTOWN, PA., wants a stand-pipe. See our Proposals.

PITTSBURG, PA.—A syndicate composed of B. F. Jones, of Jones & Laughlin, Congressman John Dailzell, Thomas and James Atterbury, and Mark W. Watson, of this city, have secured the Atterbury water-works system, and will make an offer to supply the city of Chicago with water.

CLEVELAND, O.—The Sewer Commission will have at its disposal \$4,000 to aid in the investigation of means to protect the river from pollution by sewage.

MILWAUKEE, WIS., will develop water-power on the "old mill site." Address the Town Clerk.

LOSTANT, ILL., will have a system of water-works.

PONTIAC, MICH.—A recent city election carried in favor of raising \$75,000 for water-works.

SKYMOOR, IND., will have water-works. Address bids to Henry Price, City Clerk.

MINNEAPOLIS, MINN.—City Engineer Rinker has furnished estimates for sewer-work and assessments for the next year. The total assessment is \$240,592.

TOPEKA, KAN.—The Arkansas City Land and Water-Power Company has been incorporated by C. K. Holliday, of Topeka, and others.

ATHOL, MASS.—The work on the sewerage system, provided by town meeting in July, is delayed by constitutional restrictions against increasing the town debt.

MINNEAPOLIS.—The Council Committee on water-works have favored putting in two pumps with a capacity of 15,000,000 at the new pumping station at Shingle Creek. Proposals for building the new station and furnishing the pumps are advertised for. See our Proposals.

CANNON FALLS, MINN.—Mr. J. A. Wilson, Village Recorder, writes: "We have contracted for cistern to hold 3,000 barrels of water on an elevation of 120 feet above town, to be supplied from a well operated by wind-mill alongside the cistern. Our main pipe is 8-inch. We have ordered that from St. Louis, and our hydrants, etc., from Detroit."

MOUNT VERNON, ILL.—Mr. Henry E. Ellis, City Clerk, writes: "The proposition to issue bonds in the sum of \$25,000 carried by 37 majority. A board of commissioners was appointed to have charge, and, at a meeting held September 16, the board organized by electing George H. Varnell President, and H. L. Ellis Secretary, and adjourned to meet again, after examining place of site and consultation with civil engineers."

BOONE, IOWA, will sink an artesian well.

GENESEO, ILL.—The artesian well was completed September 22; 25 additional blocks of water-mains will be laid at once.

HAYWARD, CAL.—Helbing & Donnelly have proposed to the Board of Trustees to construct water-works, if the town will pay \$3,200 per annum.

DAVENPORT, IOWA.—The Committee of the Board of Health has reported a plan for a system of sewerage. The State Legislature will be asked to pass a law permitting the city to make the needed outlay. The plan provides for a 6-inch or 4-inch outlet-sewer, with 18-inch and 24-inch pipe-sewer branches, the main to discharge some distance below the city. City Physician Cantwell, or City Attorney Fisher, will give further information.

FORT WAYNE, IND.—The City Council ordered the condemnation and purchase of the canal feeder for the purpose of supplying the city with water. S. C. Lumbard, H. C. Graffe, and J. L. Gruber were appointed Commissioners to have charge of the condemnation and purchase of the property, and will commence their work at once.

TUSCUMBIA, ALA.—All the stock of the Tuscumbia and East Sheffield Water-Works has been taken and the water from Big Spring will be distributed to the cities of Sheffield and East Sheffield.

BAY SHORE, L. I.—An agitation for sewerage has begun here.

LANSINGBURG, N. Y.—Engineer Franklin began on September 19, the preliminary survey relative to the practicability of gaining additional storage capacity for water on the premises on which the reservoirs are located.

STROMSBURG, NEB.—Our correspondent writes in regard to water-works here: "We vote on \$12,000 bonds on September 21. I think it will carry. We will furnish plans and specifications to any contractor. Address Mr. F. Fuller, City Clerk."

PAXTON, ILL., has let a contract for water works to Chicago parties.

OAKLAND, CAL.—The Board of Health has appointed a committee consisting of City Engineer Morgan and members of the board, to report on means to obtain a complete sewerage system.

DULUTH, MINN.—The Zenith Gas and Water Co. is incorporated, to supply Duluth with water from Lake Superior, and build gas works. The directors are: Prosper L. Knoppen, Dan. Pineo, of St. Paul; Henry H. Bell, of Duluth; G. G. Hartley, R. C. Mitchell, C. M. Parkhurst, all of Duluth.

RUSHVILLE, NEB., is agitating the introduction of a water-supply, with pumping-plant.

TARENTUM, PA.—The Tarentum Water Company was chartered September 21.

GLEN ELIHER, KAN.—Our correspondent writes: "As yet nothing has been done but talk. Perhaps next year water-works may be established here."

HAYWARD, WIS.—Our correspondent writes, under date of September 19: "We have decided to build the water-works ourselves, and one of the supervisors is going to St. Paul to see about pipes and other things that we need."

PAWNEE CITY, NEB.—Bids for constructing water-works here, plans by A. A. Richardson, of Lincoln, Neb., will be opened October 4.

PAWNEE CITY, NEB.—We have noted that A. A. Richardson, Consulting Engineer, of Lincoln, Neb., has prepared plans of water-works to be built here. Mr. Henry Cowperthwaite, City Engineer, writes us that bonds for \$28,500 have been voted. The specification calls for a pump with 1,000,000 gallons in 24 hours; a water-tower 12 feet in lineal diameter, 100 feet high; a masonry reservoir, and about 18,000 lineal feet of pipes, 4 to 10-inch, with the necessary castings. Bids will be opened on October 4. They should be addressed to J. M. Miller, City Clerk.

SAN DIEGO, CAL.—A land and water company to be known as the Barham Land and Water Company has been incorporated, with J. H. Dickey, C. L. Murray, R. W. McGarvie, J. P. Preston and John A. Fish as directors. The object of the company is to supply the town of Encinitas with water.

SHEFFIELD, ALA.—Address the East Sheffield Land Company about building water-works.

LOS ANGELES, CAL.—Mayor W. H. Workman has recommended to the City Council the holding of a city election on the question of raising \$750,000 for the sewerage system and \$150,000 for new parks. Both recommendations are referred to committees.

FOSTORIA, O., has decided to build water-works.

FREMONT, O., will enlarge its water-works.

NORTH PLATTE, NEB.—Our correspondent writes: "The American Water-Works and Guarantee Co. (Ltd.), of Muncie, Ind., have a twenty-five years' franchise to put in a system of water-supply for North Platte, Neb. A part of their material is now here."

BONHAM, TEX.—Our correspondent writes: "The City Council has a committee appointed now to confer with water-works builders and artesian well men on the subject of water-works for the city, and will determine in a short time what they will do."

BONHAM, TEX.—Address E. L. Agnew about the proposed water-works here. Immediate attention is necessary.

CARLINVILLE, ILL.—Under date of September 14 our correspondent writes: "An ordinance was adopted the 5th inst. letting the contract to construct water-works in our city to C. E. Gray, Jr., and associates, of Chicago, Ill. The works are to be constructed on franchise plan, and Gray and associates have sixty days from September 5 to accept. The ordinance will be published in the Carlinville Democrat and Macoupin County Enquirer this week. Both papers published in this city."

KROOK, IOWA.—Our correspondent writes: "There is no contemplation at present to enlarge the water-works in our city, and the old companies having possession originally have given up to an Eastern syndicate, but nothing is settled yet as to future business enlargements."

JACKSON, MISS.—wants water-works, and has started the movement to get them. The editor of the State Ledger is an active promoter of the enterprise.

WATERVILLE, N. Y.—George W. White, of Pulaski, has the contract for building the Waterville water-works. They are to be completed the latter part of December of this year.

ALBION, MICH., proposes to vote on the raising of \$50,000 for water-works. The City Clerk will give further information.

BENNINGTON, VT.—A syndicate of Bennington mill owners are to build a storage reservoir at Headley's novelty works for use during low water.

CLARKSBURG, W. VA.—The election on water-works by a large majority for works. Steps will be taken at once to make contracts; \$50,000 will be expended.

LAKE GENEVA, WIS.—The election on introducing water-works, recently held, went adversely to the proposition.

MANISTIQUE, MICH., will build larger water-works plant. Address the City Clerk.

LAKE, ILL.—The Town Trustees are asking for proposals for pumping-engines. See our Proposal columns.

ALBANY, N. Y.—The Water Commissioners are asking for bids on furnishing 6-inch or 8-inch cast-iron water-pipe. See our Proposals.

ST. IGNACE, MICH.—Our correspondent writes in regard to rumors about water-works here: "It is a little too soon for any information as regards water-works for this city; it's simply talk. Most of the business men are in favor of it, and there is some talk among the Aldermen of holding an election this fall and put it to a vote of the taxpayers, but nothing definite has been done yet."

GAS AND ELECTRIC-LIGHTING.

SAN JOSE, CAL.—The city has contracted with the Brush Electric-Light Company for electric street lights.

FINDLAY, O.—The City Gas Company took control September 19 of the Findlay Gas-Light Company's plant. The city gives its bonds in the sum of \$75,000 in payment.

PEKIN, ILL.—The electric-light station at Pekin was burned September 19. This accident leaves the city in darkness.

BREKLEY, CAL.—A meeting of citizens was held September 19 to incorporate the Berkeley Electric-Light Company. The plant will be constructed at once.

MARION, IOWA.—The electric-light people are still getting estimates from companies who wish to enter into a contract for putting in the plant here. The Edison and United States companies have put in bids for the work, and the Westinghouse Alternating System will also be presented.

GAS COMPANY.—In our Water Notes will be found the incorporation of a Gas and Water Company, at Duluth, Minn. Works will be built.

WOLCOTT, N. Y.—Natural gas has been struck here, and wells will be sunk and plant developed.

WASHINGTON, D. C.—The Washington Gas Company has taken out a permit to begin the work of erecting its new plant. The permit is for the erection of a retort-building to cost \$30,000, and an engine-house to cost \$20,000. When these are completed, two large gasometers will be erected.

WOODHAVEN, L. I.—The Woodhaven Gas-Light Company has been organized by the stockholders of the company doing business in East New York.

CHICAGO, ILL.—Incorporated September 16 was the Citizens' Natural Gas and Light Company; capital stock, \$1,000,000; incorporators, Joseph H. Livingston, C. W. Cray and John Moffit.

KINGSTON, ONT., is introducing electric-lights for the streets.

GREENVILLE, MASS.—The City Council has entered into a contract with the gas company to furnish the city with 25 lights at \$2.50 per month per light.

BLACK RIVER FALLS, WIS.—A gas company has been organized here with T. B. Mills, H. B. Cole, W. R. O'Hearn, of the Board of Directors.

FORT SMITH, ARK.—The Electric-Light Company, George Sagel, Secretary, has made a proposition to City Council to light the streets.

TRENTON, N. J.—The Common Council will receive at its meeting, October 4, proposals for furnishing electric incandescent lights, or lights by gas, naphtha, or other materials, to the city street lamps now lighted with gas.

ALLENTOWN, PA.—City Council at its meeting September 21, decided that during the next five years the streets of Allentown shall be lighted with 98 electric lights and 125 naphtha lamps, at a total cost of \$11,975 per annum.

CHICAGO.—Incorporated is the National Coke and Fuel Company; capital stock, \$600,000; for mining and manufacturing coal, coke, fuel, and illuminating gas, and the manufacture and distribution of gas and steam for power, heating and other purposes; incorporators, Columbus R. Cummings, James M. Flower, and George S. Willis.

AUSTIN, TEX.—The Westinghouse system of electric lighting will be introduced. Captain Molher is director, and C. F. Parmley superintendent of the work.

BAY CITY, MICH.—This city will have electric lights at \$77 per lamp per annum; contractors, the Bay City Electric-Light Company.

PAWNEE CITY, NEB.—A proposal has been made to City Council to establish a system of electric lights.

BRainerd.—The electric-light wires were placed September 16.

FORT WAYNE, IND.—A natural-gas-company will be organized by the Business Men's Exchange. Address Captain J. B. White.

CATSKILL, N. Y.—The Catskill Electric-Light Company, with a capital of \$20,000, was incorporated September 19 to manufacture electricity in Catskill for lighting the streets of Catskill and for heat or power.

CANASTOTA, N. Y.—No decision has yet been made on the electric-light question. The Village Trustees have received a bid from the American Company. They offer to put in 27 lights at \$75 each, yearly, and want franchise for five years. A company, organized by local capitalists, known as the Canastota Electric-Light Company, has offered to put in 32 lights at \$60 each, and they will probably be awarded the contract. They will use the Thomson-Houston system, and the street lights will be of 2,000-candle-power each.

PUEBLO, COL.—At a meeting of the City Council, September 12, a five-year contract with the Pueblo Electric-Light Company was entered into to light the business streets of the city by electricity. The lights will cost the city between \$4,000 and \$5,000 a year.

TOLEDO, O.—The Ohio and North-western Gas Company, of Toledo, increases stock to \$4,000,000 for enlargements.

HOPKINSVILLE, KY.—The Hopkinsville Natural-Gas Company has been incorporated; capital, \$50,000.

TUSCALOOSA, ALA.—The Tuscaloosa Coal and Iron Co. will erect a natural-gas plant.

LOUISVILLE, KY.—The Citizens' Electric-Light Company will at once erect a plant.

LAKE VIEW, ILL.—Incorporated is the Union Wave Light Company; John Hufmeyer, Hermann Koepper, and others.

TIFFIN, O.—Incorporated is the Co-operative Gas and Oil Company.

MARTINEZ, CAL.—Gas-works will soon be completed for street lighting.

CHICAGO, ILL.—Incorporated is the Lakeside Natural-Gas Company, of Chicago; incorporators, Loren H. Whitney, Rensselaer A. Palmer, and Daniel W. Albaugh.

FORT SCOTT, KAN.—The following notice is published: The Fort Scott Prospecting and Mining Company proposes sinking a 2,000-foot well in the gas-district. Propositions will be received for the location of the well until September 30. E. D. Marr, Secretary.

OCALA, FLA.—An electric-light plant will be constructed here by A. E. Waterman.

PALATKA, FLA.—Incorporated is the Southern Gas Trust and Construction Company.

OLIVER SPRINGS, TENN.—The Knoxville Natural-Gas Company has been incorporated. H. H. Taylor, President; Simon Burger, Secretary and Treasurer; E. A. Reed, Vice President and General Manager.

ANNISTON, ALA.—T. G. Foster & Co., of Montgomery, will build gas-works here.

MANCHESTER, VA.—A move is being made here to obtain electric-lights for the streets. Immediate attention is necessary.

FORT SMITH, ARK.—Chartered is the Fort Smith Natural-Gas and Power Co.; officers: Harry E. Kelley, President; J. Henry Carroll, Vice-President; Talbot Stillerman, Secretary; George T. Sparks, Treasurer; Harry E. Kelly, J. Henry Carroll, J. L. Tilly, William Breen, Henry Rentzel, L. W. Rains, and I. G. Fellner, directors.

BRIDGES.

CHICAGO.—For building the 18th Street viaduct, Chicago, over four railroads, the contract is let to the Keystone Bridge Co., of Pittsburg, for \$83,300, the construction being directed by City Engineer Artung-stall, and the bills paid by the contracting railroads, the Western Indiana, the Chicago and Alton, the Arch-chison and Topeka, and the Wisconsin Central. Only informal bids were received by the roads, other proposals being: The Pittsburg Bridge Co., for \$87,000; Detroit Bridge Co., \$95,000; Gotlieb, of Chicago, \$84,600; King Bridge Co., Cleveland, \$105,444.

ELIZABETH, PA.—A \$100,000 bridge will be built on the Monongahela River.

LINCOLN, NEB.—A city election last week defeated by a large majority the project of building the bridge which that city was to build jointly with North Platte.

TRENTON, N. J.—The Board of Freeholders on next Tuesday will consider the building of a bridge over Assanpink Creek.

DULUTH, MINN.—A bridge will be built over the Bay at Connors by the Burlington and Duluth, and the South Shore and Atlantic Railways.

DETROIT, MICH.—The Board of Public Works has received bids, as per proposals, for building the Presque Isle Bridge, and has recommended that the contract be awarded to the Milwaukee Bridge Company, at \$205,000. A special committee of the Board of Aldermen has the matter in consideration.

BOSTON.—The City Engineer has plans in preparation for an iron bridge over Charles River, and proposals will soon be asked for. It is to be built during the coming winter.

SINCLAIRVILLE, N. Y.—An iron railroad bridge will be built over Mill Creek, on Railroad Avenue. Address Commissioner Torrey.

ATLANTA, GEO.—An iron bridge will be built at Nelson Street crossing. Address Hon. C. A. Collier, Board of Aldermen.

NEWARK, N. J.—A strong movement is developed for a bridge over the Passaic River, in the Eighth Ward; estimated cost, \$75,000.

YANKTON, DAK.—A railroad bridge will be built over the Missouri River. The City Clerk will give information.

CHICAGO.—The double bridge at Madison Street has been decided upon. The plans contemplate a structure about 310 feet in length, to be swung from a pier located on the west bank of the river. The present viaduct will be supplanted by the coast end of the bridge.

COLUMBUS, NEB., will hold an election, October 17, to vote on raising \$30,000 for a bridge over the Loup and Platte Rivers.

MECHANICVILLE, N. Y.—Articles of association were signed September 17 for the organization of a corporation to be known as the Mechanicville Bridge Company, by George B. Perry, William W. Smith, George R. Moore, J. F. Terry, Stephen Lee, H. Medbery, and A. Bryan.

ROME, GEO.—Address the Board of Commissioners with proposals for building a bridge over the Oostanuala River.

FRONT ROYAL, VA.—Address M. L. Garrison here about several bridges to be built in Warren County.

AMERICUS, GEO.—Contract for trestles and bridge between Abbeville and McRae, Geo., has been given to A. R. Coulter, of this place.

WAXAHACHIE, TEX.—Bids for constructing twelve iron bridges will be received by the Commissioners' Court at this city.

KANSAS CITY, MO.—William B. Knight, Chief Engineer Kansas Railway Co., writes to correct a misstatement in a Construction Note item in our issue of September 10. Mr. Knight is building several bridges, "putting in stone culverts and masonry abutments with first-class plate-girder iron bridges instead of the present wooden trestles and structures at several points along the line in connection with the double track improvement along the road of the belt railway." The work is under Mr. Knight's personal charge.

MINNEAPOLIS, MINN.—The Council Committee on Roads and Bridges has awarded the contract for the superstructure of the Franklin Avenue Bridge to the King Bridge Company, the work to be finished by the 1st of June, 1888. The bid for the work was \$81,500.

HIGGANSUM, CONN.—The town will build several iron bridges.

VALLEY FALLS, R. I.—Engineer Cushing has prepared plans for the superstructure of the John Street Bridge. The masonry is already under contract. Estimated cost of superstructure, \$7,000. Address the Clerk of Town Council for further information.

WESTBOROUGH, MASS.—At the meeting September 28 a warrant providing for the building of a bridge over the Boston and Albany Railroad tracks will be considered.

WHEELING, PA.—The Chamber of Commerce is taking steps to have a "Union" railroad bridge built. Messrs. Tyler, Stein, and McGinley are of Committee.

ASBURY PARK, N. J.—Bids for a new bridge across the Manasquan River, between Manasquan and Burroughs, in Ocean County, will be received on September 27. The dimensions are 825 feet in length, with a draw 30 feet across, the bridge to have a roadway of 16 feet.

STEAM-HEATING, BUILDINGS, ETC.

BROOKLYN.—Charles Collins has received the contract for erecting a court house and police station at Lee Avenue and Clymer Street, at \$59,580. The work will be begun at once.

HASTINGS, MINN.—To-day an election will be held on the question of raising \$53,000 for an almshouse.

IRONWOOD, MICH.—A large amount of building will be done here at once to replace structures destroyed by fire. One of the firms to so rebuild is Bingham & Perrin, who may be addressed.

UTICA, N. Y.—The contract for improvements at the State Asylum for the Insane has been given to Charles Metz, of Utica.

TRENTON, N. J.—The lowest bidders on the proposed High School are: William Hunt, carpenter-work, \$4,730; J. W. Hooper, masonry, \$5,445.60. These bids include the steam-heating and plumbing.

SAN JOSE, CAL.—The Common Council, September 12, awarded the contract for erection of portion of the new City Hall to P. R. Welles for \$117,000.

FERGUS FALLS, MINN.—The Board of Trustees of the Insane Hospital have accepted the plans of Architect Dunnell. The building will cost about \$59,000. Specifications and proposals will be issued at once.

WINONA, MINN.—Bids for building a court-house were opened September 10 by the County Commissioners. The lowest was from Munck & Lohse, at \$105,400. It is reported all will be rejected and the plans modified.

YANKTON, DAK., is advertising for bids for the construction of a city hall.

CHICAGO.—Up to September 30 the Chicago Building Department has issued 3,008 permits, as against 2,725 for the same time last year, and the value of the buildings is \$4,000,000 more, including the \$2,000,000 Auditorium Building, now up to the second story.

FONDA, N. Y.—The contract for heating the Reformed Church with steam apparatus has been given to Pierce, Butler & Pierce, of Syracuse, at \$685.

COUNCIL BLUFFS, IA.—The contract for ventilating the Federal Building at Council Bluffs, Ia., has been awarded to William Kirkup & Son, of Cincinnati, at \$12,830.

ANTELOPE, NEB.—A city election will be held October 18 to raise \$12,000 for building a court-house.

STREET WORK AND PAVING.

SAN DIEGO, CAL.—The election September 5 on raising \$100,000 for improving county roads carried the proposition by a heavy majority. The County Supervisors will do the work.

PITTSBURGH, PA.—Orders have passed for much street-work, with sewers.

NEW ORLEANS, LA.—\$75,000 worth of gravel is advertised for to use on streets. Address the Comptroller.

ARKANSAS CITY, KAN.—Eight miles of macadamizing streets will be done here.

OAKLAND, CAL.—Contract for grading and curbing East 12th Street is given to E. J. Bates, lowest bidder. Address Clerk of Council, A. C. Henry, about much street-work which has been ordered done, on Cypress, Harrison, Hannah, 28th, and other streets.

ALAMEDA, CAL.—The opening and grading of several streets will be pushed. Address the City Clerk.

LITTLE ROCK, ARK.—Bids will be called for shortly for paving about eleven blocks of West Markham Street with Telford macadam.

ST. PAUL.—The Board of Public Works opened bids for paving Mississippi Street as follows: James Forristal, \$22,700, and sewer connections, \$50; Thornton & Shaw, \$25,000; Isaac Robinson, \$21,687, and \$40 for sewer connections; Folsom & Murray, \$24,000, and \$55 for sewer connections; H. B. Sweet, \$18,900, and \$36 for sewer connections. The contract was awarded to H. B. Sweet.

CINCINNATI.—Contracts for improvement of Pearl and Walnut Streets with granite, and Fern Street by macadamizing, have been awarded. For the first named job G. Everman & Co. were successful, their bid of \$50,074.50 being the lowest. F. Kirchner & Co. obtained the Pearl street job, bidding \$30,568.50. Kirchner will use Marlboro and Eyerman Lithonia granite.

LAKE VIEW, ILL.—The Board of Aldermen have appropriated \$21,000 to the improvement of Fullerton Avenue and other streets.

TROY, N. Y.—The Board of Contract is considering the paving of Fifth Avenue, at a cost of \$40,000. The Board holds that the work must be done.

LOWELL, MASS.—\$30,000 will be applied to street and bridge work. Alderman H. M. Fletcher will give further information.

MACON, GEO.—City Council has ordered the appropriation of \$60,000 to street improvements.

ALEXANDRIA, VA.—An expensive project is on foot for construction of a Grand Avenue, 100 feet wide, from Mt. Vernon to Washington. Mayor Smool, of Alexandria, is interested. A committee will report on organization and steps to prosecute the work.

BALTIMORE, MD.—Bids are opened to-day (September 24) by W. H. Shipley, 219 East Fayette Street, for improving Cedar Avenue. The amount of gradation will be about 53,000 cubic yards and about 1,500 perches of masonry.

LITTLE ROCK, ARK.—The Commissioners of Sidewalk District No. 4 are advertising for bids for about one mile of brick sidewalk. R. A. Edgerton, President.

RAILROADS, CANALS, ETC.

CALIFORNIA RAILROADS.—On September 12 there were incorporated the Santa Monica Outlook Railroad Company; directors, Abbot Kinney, Patrick Robertson, James Bettner, D. Galbraith, W. P. Gardiner. The road is to run from Santa Monica to the ocean beach. Los Angeles and Ocean Railway; directors, C. E. French, E. Bouton, M. L. Wicks, Jotham Bixby, Edward Records, John W. Green, A. W. Barrett, A. W. Francisco. The Wilderson Station Tract Land and Water Company; directors, W. H. Bonnell, Theodore

Wiesendanger, Clifford Evans, Van K. Dronillard, and Arthur M. Jones. The Pasadena, Los Angeles and Long Beach Railroad Company; to construct a railway from Pasadena to Long Beach; directors, John W. Green, O. J. Johnson, F. A. Atwater, William Walter Ross, G. W. Glover, Jr.

KNOXVILLE, TENN.—Articles of incorporation of the Knoxville Belt Line Railway have been filed in Hudson County, N. J., to construct railways in Tennessee. George R. Eager, A. C. Arthur, Clarence Cary, and others.

EUFULA, ALA.—The Eufaula and East Alabama Railroad will be built to Ozark. The Georgia Central will build it, and contracts will be let at once.

NAPA, CAL.—The Napa, Lake and Humboldt Railroad will be built at once.

SACRAMENTO, CAL.—The Atlantic and Pacific Railroad Company will build to Sacramento from Mojave. Surveyors are now on the line.

AUGUSTA, GEO.—Plans and specifications will be prepared by the City Engineer for the proposed levee. Dr. Eugene Foster, of the Board of Health, will give information.

WINONA, MINN.—The plans for the construction of the Winona and South-western Railway are about ready. The contract with Messrs. Hatch & McIntyre is nearly completed, and those gentlemen have negotiations completed for the purchase of the Mason City and Fort Dodge Railway as soon as they get the contract.

RAILROAD.—The Sackem and Western Air Line Railroad will build from Shelby to Cranberry, N. C. Address S. T. Pearson, Morganton, N. C.

MURFREESBORO, N. C.—Chartered is the Murfreesboro Railroad, B. B. Winborne, President.

RAILROAD.—The Lexington, Geo., Terminal Road will extend from Crawford, to intersect the projected Augusta and Chattanooga Railroad. Address Hamilton McWhirter.

GATE CITY, ALA.—Address the Gate City Land Company about a road to be built from Gate City to Birmingham.

CANAL.—The Resaca Canal & Manufacturing Co., of Resaca, Geo., has been organized, to build a canal from the Conasauga River to the Costanaula River.

MILWAUKEE, WIS.—Proposals for grading the Whitefish Bay Dumpty Railroad will be advertised for by Secretary Dupre (Mack's Block) as soon as the engineer's returns of the final survey are made.

RAILROAD.—The New York, Buffalo, and Philadelphia Railroad is sold to a syndicate of New Yorkers and Pennsylvanians, among whom is Hon. Carl Schurz, of New York City. Money has been obtained to equip it.

CHICAGO.—The opening of bids for dredging machines has been postponed by the South Park Commissioners to the second Wednesday in October.

KNOXVILLE, TENN.—McDonald, Shea & Co., of this city, were, on the 13th inst., awarded a contract for constructing a railroad from Oliver Springs to Clinton. The work is done for the East Tennessee Railroad Company.

SAN DIEGO, CAL.—The San Diego and Cuyamaca Railway has been incorporated, with a capital stock of \$1,000,000. Directors: R. W. Waterman, of San Bernardino and T. J. Daly, Q. Allison, M. G. Reffenberg, Milton Santee, I. M. Merrill, M. Klaber, all of San Diego. The line is to run to Julian.

FORT GIBSON, IND. T.—Cameron & McDonald are contractors for forty miles of the Valley Railroad from Wagner to the Illinois River.

POMONA, CAL.—Franchises have been granted to two of the proposed street railroads, the Orange Grove Street Railway Company and the Pomona Heights Railway Company. The former road has advertised for sealed proposals for construction.

BIDS OPENED.

MILWAUKEE.—Bids for constructing the proposed school building in the Thirteenth Ward were opened by the Board of Public Works September 13: Charles Kraatz, \$24,136; F. G. Horning, \$24,400; J. H. Lenecheck, \$23,900; A. H. Vogel, \$24,347; G. F. Stewie, \$23,825; H. P. Mueller, \$24,498; Oscar Knie, \$23,068; Henry Ferge, \$23,663; Frank Mirzerowski, \$22,000; John Fellenz, \$22,990; and William Klocksin, \$23,500. The contract was let to Frank Mirzerowski for \$22,000. W. E. Goodman secured the contract for doing the plumbing and gas-fitting in the building for \$834. The contract for putting in a steam-heating apparatus was let to Charles A. Barker, whose bid was \$3,095. The other bidders were: J. P. Rundle, \$1,097.50; Hazen Mooers, \$3,100; and M. Coogan, \$3,220.

PORT HURON, MICH.—The following bids for furnishing a pumping-engine (5,000,000 gallons capacity) for the water-works were received by W. H. Avery, Chief Engineer, September 15:

H. R. Worthington, New York, \$18,500.
Drane Steam-Pump Co., Holyoke, Mass., \$21,385.
George F. Blake, New York, \$23,920.
Knowles Steam-Pump Co., New York, \$16,000.
Holly Manufacturing Co., Lockport, N. Y., \$19,000.

DES MOINES, IOWA.—The following bids for iron floor-beams for Court Avenue bridge were received by Charles Bennett, City Engineer, September 15:
King Bridge Co., Cleveland, O., \$3,538, \$3,721.
Milwaukee Bridge and Iron-Works, Milwaukee, Wis., \$4,795.
Shiffer Bridge-Works, Pittsburg, Pa., \$4,790.
N. S. McDonnell, Des Moines, Iowa, \$3,280.
Kansas City Bridge Co., by J. B. Marsh, agent, No. 1, \$3,950; No. 2, \$4,075; No. 3, \$4,395.

GREENVILLE, MICH.—The following successful bids for constructing levees were received by William Starling C. E., September 12:
George Arnold & Co., Memphis Tenn., Longwood Levee, 2 3/4 c.; contents, 500,000 cubic yards.
C. Howard & Son, Pittsburg, Ind., 1 3/4 c.; contents, 90,000 cubic yards.
W. E. Ringo & Co., Mound Landing, Miss., 1 1/4 c.; contents, 100,000 cubic yards.

All bids on other works were rejected. Our correspondent adds that the work let on the high price of 2 3/4 c. is a very large levee, 2 1/2 miles long, and with an average fill of 15 feet, slopes of 3 to 1 back and 4 to 1 front; contents 500,000 cubic yards. The other prices are fairly low. Bids on enlargement work were regarded as too high, and were rejected. Most of this work has been let on private terms at better figures, to the extent of say 700,000 yards (prices, 19 to 22 cents) more.

THE SANITARY ENGINEER AND CONSTRUCTION RECORD.

MANAGEMENT OF DRAW-BRIDGES.

It can scarcely have escaped the notice of any observing man, that draw-bridges are often unnecessarily made a nuisance. The bridge-tender is supreme; and by his leisurely ways, or the laziness which often saves a closing of the draw to the extreme discomfort and unnecessary detention of the land traffic, he shows his independence of all control.

The delays in Chicago from the draws crossing the river have for a long time been very serious. Some two months ago one of the Aldermen (Mr. Clark) conceived the idea of managing the draws by telephone from a central office. Those of the bridges are styled "gate" bridges, where vessels are allowed to accumulate for passage out and in. A favorable time by a lull in the traffic is watched for, and then vessels are passed both ways. After starting them they are passed along as rapidly as possible through other bridges, and one after another bridge is closed until the next batch accumulates.

A block is often stopped by knowing in advance the approach to a narrow part of the river of two wide vessels which could not pass, one being held back until the other passes.

The result of the system, which is by no means as yet fully perfected, is that the bridges are opened but one-fourth as often as before. The following table, taken from the Chicago Tribune, illustrates the present working between the hours of 8 A. M. and 9 P. M.:

Bridges.	No. Vessels.	No. Drawings.	Total minutes.	Average minutes per drawing.	Average minutes per hour.
Rush	85	39	174	4.44	13.03
Clark	83	32	132	4.01	10.02
Wells	83	32	158	4.90	12.01
Lake	74	32	158	4.90	11.09
Polk	67	32	158	4.90	12.01

The bridge-tenders are enthusiastic respecting the new system, since it gives them so much less work; and the tug captains like it because of the rapid movement when they once get started, the result being a real saving in time to them.

The wonder is that so simple an experiment for systematizing and controlling this important matter has not been thought of before.

CHOLERA.

THE steamship "Alesia," from Naples and Marseilles, with between five and six hundred immigrants, arrived in New York Harbor last week with Asiatic cholera on board. A few years ago this announcement would have almost created a panic; to-day, thanks to our increased knowledge of the disease, of the means by which it is spread, and of the best methods of dealing with a ship thus infected, every intelligent person knows that there is no ground for immediate alarm, because the presence of the disease has been detected in time and the buildings and appliances of the quarantine establishment of the port of New York are ample to meet the emergency.

How long it may be considered necessary to detain under observation at Hoffman's Island those passengers who continue apparently well it is difficult to say, since some of them have shown symptoms of the disease and have been removed to hospital, but it is highly probable that but few cases will occur among them,

and that in a short time it will be safe to allow them to continue their journey. Their baggage is probably more dangerous than their persons as a means of transmitting the disease, and while there is no doubt that it can be thoroughly disinfected, it may be a question whether it would not be best, in order to secure public confidence, to destroy it by fire and reimburse its cost to the owners.

But, while we have no fear of the results of the present importation of cholera and no doubt as to the thoroughness with which the germs of the disease will be destroyed in this particular case, it is evident that, until cholera has entirely and permanently disappeared, not only from the Mediterranean ports, but from Europe, there must be a certain amount of danger in every ship, and every immigrant with baggage, coming from these ports. That this danger is extremely small in each individual case is true, that it is little greater than that which is due to possible importation from other ports is also true, but the sum of all the risks is a very serious item. We have a very long frontier through which the disease may find its way, and only three or four ports with quarantine stations properly equipped to deal with it even if it is recognized.

It will not do, therefore, to simply rely on quarantine to prevent danger. We must recognize the warning and do what we can to put our cities and towns into such condition that even if the germs do find their way into the country, they shall die for want of favorable conditions for their multiplication and growth. How this is to be done is well known. Municipal cleanliness, the securing of water-supplies free from sewage contamination, and the doing away with the storage of excreta are the main points to be attended to. It is almost certain that we have yet six or eight months' time in which to look after these matters, but there is no time to lose.

PECULIAR METHODS IN THE DISTRIBUTION OF THE NEW CROTON AQUEDUCT REPORTS.

A CORRESPONDENT sends us the following evidence to justify our criticism of the methods adopted in the distribution of the Croton Aqueduct reports:

NEW YORK, September 27, 1887.

SIR: I have read with much satisfaction the editorial entitled, "Peculiar Methods in the Distribution of the New Croton Aqueduct Reports," which appears in THE SANITARY ENGINEER AND CONSTRUCTION RECORD of September 24, and I feel sure that the position taken will meet with the approval, not only of professional men, but also of the intelligent portion of the community.

In corroboration of what you have stated in the article in question, it may interest you to know that during a recent visit to Alexandria Bay, N. Y., where Judge Spencer, President of the Aqueduct Commission, has a summer cottage, I found one of the much-coveted reports in question lying on a table with newspapers in one of the prominent hotels.

Being interested, I was glad of an opportunity to examine the book, and on opening the cover the first thing to attract my attention was a slip of paper, on which was printed, "Compliments of James C. Spencer," while the name of the recipient, the hotel proprietor, was written upon one of the fly-leaves. Subsequently in conversation the gentleman who received the book informed me that Judge Spencer had sent copies of the report to some of his neighbors, and that while he had no interest in the work himself, he was unwilling to part with it because it was sent in a complimentary way. From this it would appear that at least one of the Aqueduct Commissioners prefers to use this valuable technical public document to advertise himself.

THE SANITARY ENGINEER AND CONSTRUCTION RECORD ILLUSTRATED SERIES.

A RESIDENCE IN M STREET, WASHINGTON, D. C.

M. EUGENE HEUARD, as reported in *Le Genie Civil*, resurrects, before *La Société Centrale des Architectes*, the idea of a slowly moving endless train of cars, which shall, by their tortuous winding through the grounds and buildings of the Exposition of 1889, banish all fatigue from the otherwise weary legs of the visitors. This train of flat cars, whose surface is to be even with the ground, is to run so slowly that children and aged people may step on or off whilst the cars are in motion. This train is not to go on forever, but at stated periods and places it will be brought to a standstill for fifteen seconds to allow of the passage of vehicles across its surface.

M. Heuard, discussing all previously known methods of sightseeing at expositions without fatigue, objects to the rolling chairs, because they are difficult of management in a crowd, which no one will dispute, and because they make every one who uses them look like a paralytic or an invalid.

The electric tramway he disposes of summarily because it is dangerous.

The elevated railway M. Heuard admits is an ingenious affair, but difficult of access and always frightens its passengers.

All methods of transportation present to the mind (?) of M. Heuard two difficulties: (1) They are expensive, as they will not carry people for nothing; and (2) that they all have a limit to their carrying capacity.

M. Heuard then asks, what the true solution of transporting great numbers of people is, and answers it satisfactorily to himself by a very long, minute description of his *chemin-qui-marche*, as he calls his endless train of flat cars.

THE AIR OF SEWERS.

"PROFESSOR CARNELLEY, D. Sc., and Mr. Haldane, of University College, Dundee, have been investigating the impurities of sewer-air, and find that the organic acid in the sewers examined was about twice and the organic matter three times that of the outside air, whereas the number of micro-organisms was less. As regards the quantity of these three impurities the air of the sewers was better than the air of naturally ventilated schools, while even mechanically ventilated schools were more polluted with organic matter. The sewer-air contained a much smaller number of micro-organisms than the air of any class of house, and the carbonic acid was rather greater than in the air of houses of four rooms and upwards, but less than in two and one-roomed houses. As regards organic matter, however, the sewer-air was only slightly better than the air of one-roomed houses, and much worse than that of other classes of houses. The amount of carbonic acid found by the observers shows that the sewers observed were better ventilated than those investigated by previous observers. They attribute the excess of carbonic acid over that of the outside air chiefly to oxidation of organic matter in the sewage and the air of the sewer. The excess of organic matter is probably chiefly gaseous, and derived from the sewage itself. The micro-organisms in sewer-air come entirely, or nearly so, from outside, and are not derived, or only so in relatively small numbers, from the sewer itself. This important conclusion is proved by the facts that the average number of micro-organisms in sewer-air was less than in the outside air, namely, as 9 to 16; that the number increased with the efficacy of the ventilation; that the average proportion of molds to bacteria in sewer-air was almost exactly the same as in outside air at the same time, whereas one would expect the proportion to be very different were the outside air not the source from which they were derived, seeing that such a difference has been proved to exist in the air of houses and schools. Another consideration is that the filthiness of a sewer seems to have no influence on the number of micro-organisms. Further experiments in the laboratory showed that the number of micro-organisms in sewer-air is diminished nearly a half in passing along a moist tube 5 feet long and $1\frac{1}{4}$ inches in diameter, at a rate of nearly 1 foot per second. There was, however, distinct evidence of the occasional dissemination of micro-organisms from the sewage itself; especially in splashing, owing to drains entering the sewers at points high up in the roofs. It is therefore important that drains should be arranged to avoid splashing. The authors' conclusions tend to make one more doubtful of the supposed evidence of the bad effects of ordinary sewer-air, when not vitiated by splashing."—*Engineering*.

AN experiment is being made in Brussels with a portable hospital composed of slabs of leather cardboard which can be easily attached, affording facilities for removal and reconstruction in a very short time. The hospital with which experiments is being made contains twelve beds which fold up within the structure, the inclusive cost of which is £120 (\$576). It is stated to be of American design.

MUD ARCHITECTURE IN PERSIA.

A CORRESPONDENT of *Indian Engineering* thus describes the method of constructing buildings with mud in Persia: "Nearly all the buildings in Persia are built of mud and sun-dried bricks ornamented with *gatch* or gypsum.

"The principal materials which enter into the composition of a mud building are straw, quicklime, gypsum or *gatch*, and stone pebbles. Any one desirous of having a residential house in or out of town, has only to give notice of his intention to the *Mehmarbashi* or the principal architect of the city or town—generally a Persian—who either repairs to the party himself or deposes his assistant or *Bannabashi* to ascertain the size, style, and description of the building required. This obtained, the *Mehmarbashi* or architect prepares a plan which he personally takes to the *sahib* and after explaining to him the general outside features and internal arrangement, and the cost probable, he leaves it to him to decide when, where, and how the house should be built. No building is started unless the day is auspicious—*rozikhair*—and when that day is determined upon, as also the size, style, etc., fixed by the future owner of the building, the *Mehmarbashi* is sent for and the *hukum* or order given.

"Thereupon the builder commences operations. Brick-making being the first thing he sends his *falehs* or assistants to proceed with that work. The bricks are made of clay previously prepared. This is done by first digging the ground and allowing the clay to remain exposed for two or three days in the sun. It is then saturated with water and exposed for two days longer, when it is subjected to the operation of *treading* or tempering. The clay is then molded into bricks $9\frac{1}{2} \times 2$ inches, and the surface is luted over with water mixed with chopped straw or *kah*, of which seven seers are used for every 1,000 bricks molded. This superficial plastering of straw is intended to prevent the newly-made bricks from cracking. A single molder can manufacture from 2,000 to 2,500 bricks per diem of six hours. The cost varies from eight to twelve annas per 1,000, and sometimes more when they are intended for the kiln.

"When the bricks (sun-dried) are ready, the *Mehmarbashi* marks the foundations according to the *rung* or plan, and the pits or trenches are then dug and the whole exposed for several days, generally one week, until the trenches and *debris* from the same are quite dry. The clay thus dug is of very tenacious character and is called *roost*, a kind of fire-clay. The foundation is laid in with this clay mixed with quicklime. It is well tamped and rammed and then allowed to stand over for a week. The thickness of walls is determined by the weight and height of the superstructure and is invariably spoken of as so many *fingers* breadth. The walls are built with unbaked bricks and clay and the arches with the same bricks and *gatch* or gypsum. A *bannabashi* or a mason seldom uses the rule or plumb-line when building a wall, his guide to straightness and verticality being the eye and the trowel.

"The small arches—of which there are many varieties—are never built with centrings as in this country. It is sufficient when the first ring is made; all others follow it endwise until the whole arch is completed in. It is made of a single brick on edge and kept in position in course of construction by means of the *gatch* and wedges of pebbles. The *gatch* dries as soon as applied on the edge of the bricks, which are pressed or placed in position before it dries or *dies*. The pebbles are used as wedges only in the extrados joints of arches where the joint is wider than in the soffits. The circularity of the arch is determined by means of a line or string from the centre of a bar placed along the springing of the arch, or rather span, or parallel to it, the said string being equal to the radius of the circle of which the arch is a part.

"Where arches exceed 10 feet in span and 30 or 40 feet in length, arched ribs are put in over centrings placed 10 feet apart and the arch-work of the spaces is filled in, as before, with bricks on edge—single—but without the help of centrings. Except in *tarbi* or extra strong arches where the bricks are used on their planes or flat—i. e., endwise—all other kinds of arches, such as the *gabri* or *Parisi*, which is never or seldom built without *shaloob* or centring; the *almastrash* or diamond-shaped, and the *ghace* or pointed—Gothic—are invariably built of single brick on edge.

"When the arches or domes are completed the spandrels or *sandooghas* are filled up with broken bricks carefully arranged. Over this is laid fine loose earth, which is rammed down to the required level preparatory to receiving the *kahgil* plaster, which is prepared in the following manner: The clay, to which is added chopped straw, is first made and well tempered by the feet. It is then allowed to stand for several days with water just covering the top of the clay, which is mixed in small tanks. When thus prepared it is laid over the loose earth which had been rammed level previously, and thus the roof is completed.

"The thickness of the *kahgil* plaster for the roof ranges between 3 and 4 inches. After the roof is completed the

parapet walls facing the streets and the neighboring buildings are raised 5 and 6 feet above the level of the roof, tapered, and similarly plastered with *kahgil*. The facade of the building is either plastered over with *kahgil* of finer quality colored with red or yellow ochre, and lined and paneled out in *gatch* or gypsum, or entirely plastered with the latter, and ornamented with moldings of the same material. The interior of the building—the rooms—are generally plastered with *kahgil* of the finest quality, called *sungil*, which is composed of fine clay, the husk of wheat, horse or cow dung, and the coloring matter. These are mixed in large vats and allowed to stand for several days—seven or eight days—when the clay is considered ready for use. It is then applied to the wall with a trowel, care being taken that it is uniformly laid. The projecting angles of walls and recesses are picked out in *gatch* and colored to suit the *kah*, or rather *sungil*, plaster.

"A single mason will lay in 2,000 bricks for a day's work. When the wall rises beyond the reach of assistants or bearers of bricks and clay, the bricks are not taken up in hod or basket, but are thrown up from hand to hand to men placed on scaffolds or stages until they reach the bricklayer. Leather gloves are worn by the throwers to save their hands from injury arising from the constant friction between the bricks and the palm of the hand.

"*Gatch* is only used in building of arches or moldings, and is never mixed up in larger quantities than a few seers at a time when employing it as a cementing material or for moldings. When in course of preparation for these works it is kept in constant motion to prevent it from *dying* or getting flat, and therefore useless. The *gatch* is much appreciated for its quick-setting and adhesive properties. It is the only and best cement used in arched masonry and moldings.

"The enclosure walls of the house are sometimes carried to great heights—30 to 40 feet—as a protection against thieves. They are built solid about two-thirds of the height, the remaining portion being built in *sandooghas* or chambers which run along the length of the wall—generally of enormous thickness at the base and gradually tapering to a point or edge.

"This is the *modus operandi* of building an ordinary dwelling-house, and though the same method is observed in the construction of more pretentious buildings, public or private, the difference is only in the choice of materials. There are huge buildings three and four stories high built of sun-dried bricks faced with burnt bricks, and the joints filled in with lime or fire-clay and glazed green or blue. Vaulted bazars are entirely built of sun-dried bricks decorated with figures and flowers in gypsum. The perfection to which clay has been carried in the constructive art is evidenced in the former and the present capital of Persia by the magnificent caravanserais known under the name of *Caravanserais Mukhlis*, the buildings in *Charbagh* or four gardens, the public buildings in *Maidanishah*, and last, but not the least, the *Halfdast* or the royal palaces, old and new."

INCREASED rapid transit for New York in the near future seems to be delayed in the same way as is the "Metropolitan" of Paris—namely, strangled in red tape, injunctions, and strife between advocates of the elevated and the underground systems. M. Boudenot, in *Le Genie Civil*, gives the following comparison of estimates, which will be of interest to the advocates of elevated structures as against underground transit, looking at the subject from a Parisian standpoint:

UNDERGROUND.	ELEVATED.
43 kilometres, slow, dangerous, disagreeable and not easily accessible.	63 kilometres of real railroad, rapid, agreeable, and easily accessible.
Total cost 387 millions francs, 9 millions per k. m. constructed.	Total cost 525 millions (but 20 k. m. more road), 9,300,000 francs per k. m. constructed.
Return on capital invested 3½ per cent., consequent loss on guarantee by the French treasury of 8,800,000 francs per year.	Return on capital invested 4 per cent., consequently loss of only 500,000 francs per year on the treasury guarantee.
Service rendered the public: Carrying capacity 50 millions of the 300 millions who now travel with the present conveyances.	Service rendered the public: Carrying capacity, 120 millions; besides the opening and rendering more healthy of new boulevards, streets, etc.

A RESIDENCE IN M STREET, WASHINGTON, D. C.

ARCHITECT UNKNOWN.

SKETCHES AT CHATHAM, FREDRICKSBURG, VA.

AN International Tramway (street railways) Congress has just been held in Vienna, papers being read on the establishment of a universal statistical bureau of tramways, fares, transfer-tickets, American street-tramways, and electric tramways.

ACCIDENT ON THE NEW CROTON AQUEDUCT.

COLLAPSE OF BULKHEAD.

A DISASTER occurred in the tunnel of the New Croton Aqueduct September 9, 1887, which was due to the collapse of the bulkhead in south heading of Shaft 17.

In order to intelligently understand the nature of this accident it will be necessary to give a brief description of the mode of working this heading, which is in soft material composed of sand and gravel. The system adopted for working in material of this character is called bar-timbering or English system, and the distinctive feature is the use of top-laying bars for holding the roof, while the whole lower portion is taken out, which leaves a clear open space for building the masonry. This system is supposed to have been first introduced in this country when the Allegheny Tunnel, on the Pennsylvania Railroad, was constructed in 1851.

In soft ground a drift is first driven clear through the length of timbers used, which are about twenty-one feet long; but the length of the drift is less, as a portion of the drawing-bars rest on the completed arch and short struts at opposite end, leaving the length of heading about sixteen feet.

The top of the drift is three or four feet above the extrados of the arch to be built, and nine feet wide. In starting the work an opening is made large enough to insert a square piece of timber 10x10 inches and nine feet long, shown at *p* in Fig. 3, which is supported by three posts of the same size, indicated at *m*, that vary in length from five to eight feet as circumstances may require.

A plan of this drift is shown in Fig. 4. On the top of the timbers *p*, poling-strips, or lagging, about six feet

The lower timbers are shorter than the crown-bars, and are not drawn forward, but left in place, and the pockets between them filled with masonry. As the depth of the excavation increases, the short posts supporting the crown-bars and caps are removed and longer ones substituted. The sills A, B, and C, indicated in Figs. 1 and 2, are inserted to support the permanent vertical posts, and form part of the bulkhead. The back of these timbers below A is lined with lagging to retain the sand in place, and thereby protect the subsequent construction of the masonry. A foundation for the brick-work is prepared by first laying timber longitudinally, and covering it with timber similar in character transversely. No attempt is made to place the poles regular in position on the arch, it not being necessary, as the section is always made larger than required to admit the masonry.

When the material has a tendency to run, the lagging and poling-strips are calked with hay, and, if necessary, where pockets are formed, they are lined with hay also. Where thought necessary for security, the timbering is carried down to the foundation, but Fig. 1 shows the timbering of this section to end three feet above this foundation. The full black line below lower sill C, Fig. 1, indicates position of sand in the sides of heading; the broken circular lines the relative position of masonry. The square timbers are 12 inches square, and round timbers 12 to 24 inches in diameter.

On the day of the accident the sills A, B, and C, and the struts resting on sill B, including the posts *a* to *g*, were in position. The brace E and short posts D and F, also a centre post back of brace E, were in place. The sills B and C were braced at their ends on each side of the heading by timbers abutting against the masonry shown in Fig. 2 at J and H; in fact, all of the timbering repre-

resulted in undermining it and the posts *a* to *g*, the weak point being shown in section at R Fig. 2.

The sand in this section was probably more shifting in character than any passed through in the section preceding it, and this condition did not develop until the moment of collapse. The open space three feet in height may have contributed to the weakness.

The force of the air was so great as to extinguish all the lights, which greatly increased the terror of the disaster. Fourteen men were at work in the heading and all except three escaped. The bodies of the men who were suffocated were found at the end of the invert of completed masonry, and had been caught by falling timbers.

Everything was done which it was thought would contribute to safety; the preceding three sections having been worked in the same manner without any accident occurring.

ARTESIAN WELLS IN IOWA.

THE recent severe drought has turned the minds of farmers and others in Iowa to the subject of obtaining a supply of water from the earth. The *Iowa State Register* has given a number of articles calling attention to the success attained in the search both there and elsewhere, Des Moines and vicinity being the point more especially considered.

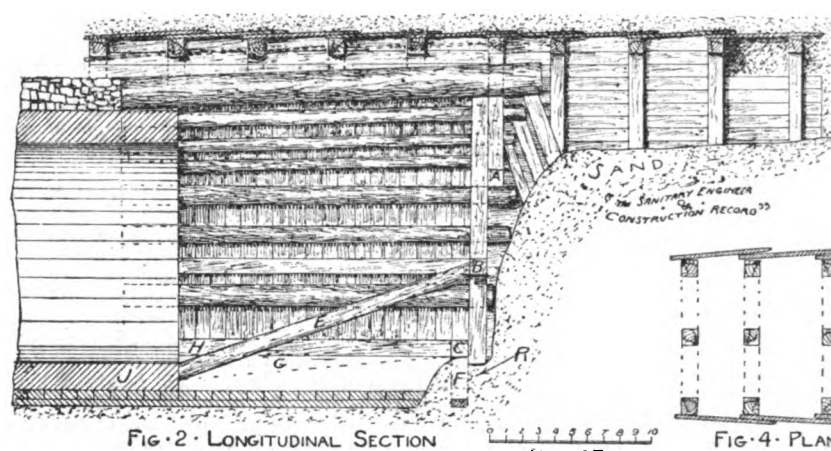

A recently driven well at the Capital City Hotel is 205 feet deep, and supplies 1,700 gallons per day, rising 9 feet above the surface. The cost of boring by hand was \$1 for the first 100 feet, and \$2 for the second 100. A further boring of 71 feet in granite added nothing to the supply. The cost of a 500-foot well is put at \$1,500.

It seems that one water-bearing stratum is found near the surface at about 30 feet depth, a second at 200 to 350 feet, and a third at a depth of about 1,400 feet. An in-

long, are driven inclined upwards as soon as the material in advance is loosened. The work is then progressed by carefully removing the sand from the top and inserting lagging on each side, as shown in Fig. 4 at *k*, to prevent the sand from running when this advance drift is being widened. As soon as practicable another drift-cap is inserted and supported by a centre post. When the sand outside of the lagging in this advance drift is sufficiently loosened, or pockets are formed, poling-strips are driven on each side parallel with the drift, the V-shaped lagging removed and the end posts inserted under the drift-cap. This process is repeated until the drift is advanced sufficient to draw in the crown-bars, which are placed from three to four feet apart from centres. These crown-bars are from eighteen inches to two feet in diameter. When drawn in position they are first supported at the forward end by short posts, the rear end resting on the completed arch. Poling-strips are driven transversely over these crown-bars, as shown in Fig. 3 at *k*. The forward end of the crown-bars are inclined upwards to permit them to be lowered free from the roof before advanced in the next drift.

The heading is then widened to permit two more crown-bars, one on each side, to be inserted, these bars being separated by braces indicated in Fig. 1. Four to six of these bars are called also drawing-bars, as they are drawn forward from section to section, unless they should become so firmly fixed in position that it would be cheaper to abandon them and use new timber. The heading is brought to the full width and depth required by inserting alternate timbers on each side until the necessary depth and width required is obtained, the transverse poling-strips being continued to the bottom.

sented in Fig. 1 was in place. The side braces holding sills B and C were heavy oak timbers. The three preceding sections had been timbered in precisely the same manner without any accident occurring. The work was examined in the morning by Alfred Craven, the Division Engineer, and also by Gaylard Thompson, the assistant engineer in charge, and they considered this bulkhead to be as well secured for safety as any that preceded it. In the afternoon Mr. Thompson advised Mr. Breuchaud, the Superintendent, to put a brace at centre of lower sill, to rest against the invert at J, as indicated by the dotted line at G in Fig. 2, but this suggestion was made as an additional precaution only. Before the accident occurred, the order for this brace had been given by the superintendent, and preparations made to insert it, but the collapse came before the brace could be put in position.

As an examination had been made previous to the accident, it was known that no voids were left over the poling-strips to permit the sand to run, as the sills were resting on the poling-bars indicated by dotted line over large bar in Fig. 2.

When the accident came it was without a moment's warning; the whole timbered section appeared to fall down at once, and the entire heading filled with sand immediately, except a small space at the crown. The crown-bars did not break until they struck the bottom. The timbers on the east side appear to have fallen all the way down, but the timbers on the west side were partially held up. The supporting struts on the east side fell with the bars, but the struts on opposite side remained up. As the posts *a*, *b*, *c*, *d*, *e*, *f*, and *g* rested on the sand, the removal of this material in front of it within two feet of lower sill C is supposed to have started the sand in motion, which

interesting fact has been noticed that along a certain strip of territory lying in a north-west and south-east direction, water is sure to be found, while failures have occurred at other points. The usual experience has been noted, also, that a heavy draught on the water at one point affects the supply at other points in the vicinity.

At Belle Plaine several artesian wells were developed until the great geyser was struck. Before that the wells threw the water 80 or 100 feet high; since it has been confined they have begun to spout again.

Commenting on the present scarcity of water, the *Register* says:

"The creeks, brooks, rivers, and springs, which used to be so abundant and so unfailing, have not only dried up under the scant rainfall, but the common supply of water by wells has also failed to a serious degree. Farmers who never wanted for water in thirty years, either in creeks or wells before, have suffered from want of it in the past two years. The natural process of streams lessening in volume as a country grows older, added to the dry weather we have had for these two years, has dried up many surface and under-surface streams. As one farmer remarked yesterday: 'Digging for wells no longer avails. The first vein of water which could always be tapped in Iowa from twenty to thirty feet in years past, has gone dry, and now even the second vein, forty to sixty feet below the surface, very often fails. If the dry weather continues another year, we shall have to depend on artesian wells.'

"In Des Moines and its suburbs are perhaps a dozen artesian wells—the most of them 200 feet deep, none over 350. But other holes or shafts in or near the city sunk 600 or 800 feet deep have failed to develop artesian wells. In boring for natural-gas, within six miles of Des Moines, in the direction too of the artesian-well fields in Story and Hamilton Counties, some holes have been sunk as deep as 1,700 feet without finding artesian wells. Of the numer-

ous wells in these explorations, only one six miles from Des Moines and 800 feet deep has developed artesian water, and it delivers the stream forty feet high, and yields five barrels of water a minute."

It is stated that a flowing well exists in France which was bored in 1126. In Iroquois County, Ill., there are over 200 wells within a radius of 20 miles of which the average depth does not exceed 70 feet.

Shale, sandstone, limestone, and chalk have all yielded copious supplies in many localities.

Professor Frank Laverett gives a discussion of the question of the requisite conditions for a true artesian well as follows:

1. A pervious water-bearing stratum.
2. An impervious stratum below.
3. A second impervious stratum above the water-bearing stratum.
4. These must be inclined.
5. There must be no adequate outlet for the water at a lower level than the water.
6. A sufficient collecting area or reservoir with the porous stratum.
7. The collecting area must have sufficient elevation to act as a fountain-head.
8. There must be a continuity of the permeable bed.
9. There must be no flaw or breach in either of the confining beds.

The previous water-bearing stratum is usually sand or gravel or sandy clays.

The impervious strata are usually of some compact clay or agglutinated pebbles, or of hard rocks. The necessary inclination of the strata is given by Professor Chamberlain in Vol. I. of Geology of Wisconsin as at least one foot per mile. This is quite an important condition in rainless regions, where the water-supply may flow in subterranean beds for hundreds of miles, which makes it necessary that the collecting district shall be elevated so many hundred feet above the permeable bed where it is tapped. The fifth condition will be better understood perhaps by illustrating with an inclined tube representing the permeable stratum, the walls the confining layers. Suppose water is flowing through the tube so rapidly that it is full, and that near its lower end an opening be made on the top of the tube. If the water does not have an adequate outlet at the lower end of the tube it will be forced out through this opening, and illustrate the jet of water from an artesian well, but if the water flows freely out of the lower end of the tube it will not be forced out through this opening in the top. The sixth condition was overlooked in boring for a well at Colorado Springs. This city is so near the mountains that the collecting area, which is only a few square miles and in a dry region, is utterly inadequate to saturate the pervious beds which underlie the city, and are otherwise favorably situated for yielding artesian wells. The seventh condition, I think, finds illustration in the artesian well districts of Iowa.

The eighth and ninth conditions have often been neglected in a study of well districts, and have a claim to close attention before the study of a district is complete. There has been loss in two ways, which are singularly in contrast to each other. Sometimes a region but partially studied, and faults or breaks in the strata neglected, has disappointed the confident persons who rely on strata being undisturbed and continuous throughout districts of wide extent. They made a boring with their theoretical sections of strata, perhaps drawn on a map hanging near by, and find that a fault or break or change in the character of the strata below has entirely spoiled their calculations.

A second way in which wrong notions obtain prevalence is due to an imperfect or incomplete study of a region in which certain places are found in which artesian wells cannot be obtained, and it is at once concluded that the whole region is not favorably situated for obtaining artesian wells. This idea prevails perhaps until some one unintentionally strikes a favorable place and obtains a flowing well. There is likely then to follow a great expenditure of money in prospecting for wells anywhere and everywhere over the region regardless of what was taught by the early experiments and failures.

It may be by this time be in the mind of the reader to say, "What can the geologist tell us about artesian wells if there are so many conditions affecting their being obtained?"

I will candidly admit that the subject of the favorable places for obtaining artesian wells is one that requires more than theoretical study. As complex and ever-changing as the strata are, there is a necessity for actual sections obtained from borings, and these borings should be sufficiently abundant to give confidence in what they reveal concerning the character of strata, source of water-supply, height to which water will rise, etc. The geologist requires all this, and more too, aside from his theoretical knowledge of wells, before he can be considered as authority on this subject. He then has a work which no one else does—viz.: To collect facts and arrange them in the form of a report which will show the present status of knowledge of the region, so far as this knowledge relates to artesian wells.

UTILIZATION OF WASTE PRODUCTS.

WE give an engraving of new machinery recently introduced by the Corporation of Burnley, for converting old setts, broken flags, masons' scalplings, boulders, rough gravel, old bricks, quarry refuse, etc., into fragments of

any desired size for concreting purposes, or into sand for mixing with the same; shingle or racking of a cubical form for inserting between the joints of paving to be afterwards grouted with asphalt or cement, and materials for tar-paving, at a cost of 3d. per ton. Any apparatus or arrangement having for its object an improved method of preparing and producing materials for engineering works—especially if capable of utilizing waste substances such as are mentioned above, and at a nominal cost—must be interesting to municipal engineers and surveyors. There have been for some years past crushing-machines, mostly with revolving screens, made in Leeds, Manchester, and elsewhere; but as we have not had an opportunity of examining them we are not able to speak as to their action. We understand that this description of machine was formerly used in the town of Burnley, but it was found that the circular revolving arrangement did not sufficiently separate the different sizes, an objection engineers frequently raise against this form of screening, especially in reference to broken stone for concreting purposes, and shingle or racking for paving works. On account of the broken stone not being perfectly clean and free from small particles of dust, etc., a greater portion of smaller material than is specified is contained in the aggregate, which consequently adulterates the cement, and greatly reduces the strength of the concrete; and the shingle or racking not being per-

fectly clean and free from finer particles and dusty substances, the asphaltic mixture for grouting will not adhere to it, and the paving is not rendered impervious.

With regard to the machine illustrated above, and which has been invented by Mr. John E. Stafford, A.M.I.C.E., the Borough Engineer of Burnley, the materials to be dealt with are put into the reducing-machine (not shown on engraving), which can be regulated to make different sizes. They are then conveyed by an elevator to the screening apparatus, and separated into as many sizes as are required at one operation. All the material too large for the size required is returned to the reducing-machine to be broken again. In sifting the contents of dust-bins, etc., which is at present done by females and youths in some of the vestry-yards in London, the boot or receiver at the bottom of the elevator is dispensed with. The elevator is extended so as to reach to the bottom of a sloping pit sunk below the surface of the ground, and into which the dust-cart empties its contents. The dust, etc., fall by gravitation into the elevator buckets, and are conveyed to the top of the screen. Rags, pieces of paper, etc., are automatically intercepted and collected before entering the screen; old tins, bottles, hard and soft core, and fine dust being separated as required. The latter is prevented from escaping into the atmosphere, as is the case when being sifted by hand. It should be stated that an important feature of this machine is its having a combined radial, oscillatory, and positive shaking action, being precisely similar in

motion to riddling by hand. The material is turned out as cleaned and distinctly separate as if it had been washed.

Among some of the advantages of this apparatus, six different kinds of material, varying in size from the finest dust to stone for concreting purposes, can be produced at one operation, and automatically discharged direct into carts or wagons at a saving of one-half the cost of the arrangement generally in use. All the materials are perfectly clean, separate and distinct from each other, and ready for immediate use. In producing materials for concreting purposes, the machinery can be regulated to produce the specified proportion of sand required. River gravel and waste material, such as old bricks, broken flags, boulder, etc., can be reduced to angular fragments, and used for spreading on wood and granite pavements in wet and very hot weather. The construction of the machine is of a very simple and ingenious description, and can be erected on the ground-level, thereby saving cost of expensive elevated foundation, and curtailing the expense of working. Considerably more material can now be treated than could formerly be dealt with by the old breaking-machine and circular revolving screen arrangement, and the products are more uniformly cubical in shape, and much less wear and tear of machinery and waste of material is experienced.

We are informed that since the introduction of the system at Burnley a saving of £200 per year in working expenses alone has been effected in the production of shingle or racking for paving purposes. The various materials are required in enormous quantities in towns, especially where impervious paving is put down, and the average cost per ton in the majority of towns using at least 10,000 tons per annum is as follows: broken stone, 2 inches, 3s. 9d. per ton; shingle or racking, 6s. 6d. per ton; and fine sand, 4s. per ton—an excess of 75 per cent. compared with the cost of the materials at Burnley.

PAVEMENTS AND STREET RAILROADS.

WOOD PAVEMENT IN THE METROPOLIS.*

THE DISCUSSION.

MR. G. H. STAYTON said he had been told that his paper did not deal with the obnoxious smells sometimes experienced in connection with wood pavement. He thought, however, that he had dealt with the subject fully under the head of management; he had certainly intended to do so by drawing attention to the absolute necessity for a plentiful supply of water for the purposes of cleansing. Of some samples of wood pavement which he exhibited, one block had been taken up from Oxford Street a month or six weeks ago, and it showed that wood pavement could be worn down to the thickness of a mere crust, and still retain a fair surface. It was originally about six inches in depth, and was laid in 1878. The wear was simply owing to the traffic upon it.

Sir Joseph Bazalgette, C. B., president, asked if the author could give any further opinion on the subject of traction and foothold with wood pavement as compared with other kinds of pavement.

Mr. Stayton said he could give no further opinion on the subject. It had been exhaustively treated a few years ago by Mr. W. Haywood, the city engineer; he had not, therefore, thought it necessary to deal with it again. The average thickness of the pavement at present in Oxford Street was about 3.30 inches; but at certain parts it was not thicker than the block to which he had drawn attention (1 3/4 inch), which was a fair specimen of the pavement at those parts where the traffic was concentrated.

Mr. W. Lawford remembered when, in 1841, a part of Whitehall and a part of St. Giles were laid with Rankin's patent wood pavement. It was down only six or eight months when it failed, owing, as he believed, to insufficient drainage and a bad foundation; besides which the cost came to £2 10s. or £3 per square yard. The success of the present wood pavements was no doubt largely owing to the good foundations on which they were laid. He remembered seeing the pavement put down between the Chapel Royal, Whitehall, and the Horse Guards. There was no concrete, but only a wood framing as a sub-structure. A full description of it, with illustrations, would be found in the *Civil Engineers' and Architects' Journal*, for September, 1841.† From the same publication he found that in 1838 many streets in Philadelphia were paved with wood, and he believed that the pavement remained to the present day, but he did not know the results.

Mr. W. Weaver considered that some apology was due from him as Surveyor of the parish of Kensington, where by far the largest area of wood pavement had been laid, for not having presented a paper on the subject to the Institution; but as the terms under which he held his appointment involved the devotion of his whole time to

* Henry Stayton, Assoc. M. Inst. C. E., and president of the Proceedings.

the duties of his office, he had come to the conclusion that he could not abstract from those duties the time necessary for the preparation of such a paper. He agreed with the author in the three propositions at the end of his paper, especially the third, that notwithstanding many former instances of failure, the modern system had achieved a fair amount of success, and that there was no apparent reason why its use should not be extended. So far from there being no apparent reason why its use should not be extended, he thought there was a good apparent reason why its use should be very much extended in consequence of an injunction that had lately been granted against his board with reference to the use of steam-rollers. If that decision was not upset (the parish authorities were about to appeal against it) he did not think the public would like to revert to the state of things existing twenty years ago, when the traffic had to plough its way through the newly-laid macadam, and in such case wood pavement was likely to extend very much. There were some details on which he could not quite agree with the author, one of which was the statement that wood pavement was laid down better and cheaper in Chelsea than in any other part of London. In Kensington seven different kinds of pavement had been tried—he believed every known kind except Carey's keyed-joint—and the result of his experience of those systems had led him to believe that the most economical wood pavement that could be laid was the plain deal, if it was to be laid under competitive tenders where the wood had to be inspected to see that it was of a proper description; but if the work was not tendered for, if a good price was given for a good article, and it was wished to have the work done expeditiously, he preferred the system of the Improved Wood Paving Company with pickled blocks and asphalt joint. The work was got through much more rapidly in that way, and from the results in Kensington, he was sure that the system would last as long, if not longer, than the plain system; the cost, however, was about 1s. 6d. per square yard more. The assumed superior merits of the wood pavement in Chelsea appeared to be due, according to the author, to the work having been executed by his own staff and the substitution of studs for asphalt or laths. But he could not see the advantage of the parish doing the work with their own staff. If they invited tenders for the supply of so many tons of Portland cement, so many cubic yards of Thames ballast, and for breaking up the surface, they had merely a series of competitive tenders for the work in detail, whereas in the other case they had one tender for the complete work; and he thought that the one profit in the latter case was less than the various profits in the other. He might mention a practical illustration which had come under his own notice in the Fulham Road. It was the last extensive piece of work that the author had done, and at the same time Mr. Weaver was paving a portion of the same road under his charge extending from the Brompton Oratory to Thistle Grove. In his own case, the work was done by Messrs. Nowell and Robson under contract, at 9s. 5d. per yard, whereas in the author's case it was 10s. 3d., or 10d. a square yard more, and the time of execution was about forty per cent. longer. It would be apparent to every one practically acquainted with the subject that it was necessary to consider not only the question of cheapness in first cost, but the interests of those who were to find the money for the execution of the pavement—namely, the ratepayers, some of whom were abutting frontagers; and it was a matter of considerable moment to a shopkeeper on a line of thoroughfare to have his receipts diminished £5 or £20 a week in consequence of the road being up. Time, therefore, was of great importance. Again there was a great disadvantage in having to pick up the laborers almost as they came; it might take several weeks to get them into working condition; but if the order were given to an established firm they could at once send a number of men of experience in their several departments, so that they would get half-way through their work before the others had started. The question as to when it became economical to substitute wood-paving for macadamized roads was an important point for a board to consider when about to launch a large wood-paving loan. His figures were not quite the same as the author's, but they came to very much the same in the result. He was not able to separate the scavenging from the maintenance; but he had always advised his board that if a macadamized road cost 1s. 6d. per square yard per annum for maintenance, it was cheaper to put down a wood pavement, and that was a very similar conclusion to the one at which the author had arrived. With regard to the question of studs, he had tried various kinds, single-pointed and double-pointed, but his experience was that they did not produce such regular jointing as asphalt or lath-joints, the lath being left in. If the lath was withdrawn, the brooms passing over the surface sweeping in the liquid grout disturbed the regularity of the surface. Studs were generally driven in by boys, who were not models of carefulness, hence some were driven in very hard (perhaps after the men had had their dinner), while in other cases, when the men were tired, a good deal of the stud projected. He would leave the practical point as to superiority to be decided by members who could examine and contrast the two pieces of pavement in the Fulham Road to which he had alluded; that east of Thistle Grove, executed by Kensington, and the other portion west, carried out by Chelsea.

Mr. L. H. Isaacs regretted that he could not agree with either of the three proposals which the author had asked the institution to indorse. The paper appeared to be written with optimistic views, the author having charge of

a suburban or semi-suburban district, and apparently not being aware of what actual London traffic was. The instances of wear and tear which he had cited were confined to King's Road and Sloane Street. Mr. Isaacs desired to set against them the experience he had obtained in a central portion of London over which London traffic, in the strict sense of the term, actually passed. The statement that wood pavement was calculated to last seven or eight years was, he thought, misleading. He was ready to indorse all that had been said as to the comfort and convenience of wood pavement, but the question of cost ought also to be considered. The author's first proposition stated that where the ascertained cost of maintaining and cleansing a macadamized carriageway exceeded 2s. 2d. per square yard per annum, or where the traffic was so considerable that a quieter and cleaner pavement was deemed essential, the substitution of wood was desirable. He entirely agreed with the second part of the proposition, but the first was wrong. The author had admitted that the statistics of his own office showed that the cleansing amounted to 11d. per square yard per annum, leaving for maintenance 1s. 3d. per square yard per annum. If he had gone to London proper, he would have found that the cost of mere maintenance was from 6d. to 1s. In his own district the cost in some streets was 6d., in others 9d., and in the majority 1s. Mr. Weaver had stated that about 1s. 6d. was the proper sum due to maintenance. Which was right? Or would engineers be justified in rejecting the advice of both, and taking instead the evidence of a man like Mr. Haywood, the City Engineer, who had charge of streets over which true London traffic passed? With regard to the economy of wood pavement, the author had clearly failed to prove his proposition. It was certainly convenient, indeed luxurious, and where the ratepayers were willing to pay for the luxury, there was no reason why they should not have it. When a rich banker drew a check for the rates of his premises, rated perhaps at £10,000, it was of little consequence whether the amount of the check was £1,500 or £2,000. In like manner it was a matter of indifference to a wealthy inhabitant of Prince's Gate whether in drawing a check for the rates of his house the amount was £160 or £200. Such persons would rather draw for a larger amount and have the comfort of a noiseless pavement, than draw for the smaller amount and revert to the old state of things. The author's third proposition "that notwithstanding many former instances of failure the modern system has achieved a fair amount of success, and that there is no apparent reason why its use should not be extended" had been drawn with great caution. There had been no doubt "a fair amount" of success, and enormous improvements had been made in the wooden pavements of the present day, as compared with those put down twenty-eight years ago; but, after all, the question was very largely one of cost. He would invite the members to consider Chancery Lane, Southampton Buildings, High Holborn, Lamb's Conduit Street, Hatton Garden, and Great Ormond Street, which it would be admitted were fair representatives of streets with ordinary London traffic. They were all under the jurisdiction of the Holborn District Board of Works. Chancery Lane was first laid with wood in the Michaelmas quarter of 1876 by the Improved Wood Pavement Co., which he thought was one of the best wood-paving companies in London. The area was 1,960 square yards, and the first cost was £1,557 10s., or about 15s. per square yard. The complaints against it were numerous and grave. It was laid on the principle adopted by the company of transverse boards, with concrete as a foundation. The noise of the traffic passing over the granite pavement which previously existed was so great that the dwellers in Stone Buildings and Chancery Lane petitioned the board to lay down wood pavement, and even offered to contribute to the cost; but after it had been down a few years they complained of the shaking of the windows and the general unpleasantness, and asked that it might be taken up again. The company, on being communicated with, stated that they had come to the conclusion that the system adopted was a mistake, and that they were prepared to alter it. To their credit it should be stated that they took up the whole of the pavement and relaid it at their own cost upon their modern improved system, with entirely new blocks and new materials. That was in 1881, and no complaints as to rumbling and vibration had been made since that time. If the pavement lasted till 1886 he should think it would have done its duty, and he would have no cause of complaint. The wooden pavement of Southampton Buildings, where the traffic was much lighter than in Chancery Lane, was laid down in the Christmas quarter of 1876. It contained 1,063 yards superficial, and the cost was £824, or 15s. per square yard. It was largely relaid in the year 1882. The first pavement that he took in hand when he was appointed Surveyor of the Holborn District was the wood pavement in High Holborn, which he removed, and for which he substituted granite pavement in 1857. In the Christmas quarter of 1877 a wooden pavement was laid down in High Holborn. The portion in the Holborn District contained 3,842 yards superficial, and its cost was £3,030 1s., which again was about 15s. per square yard. That pavement entirely failed to carry out the views, not only of himself and of the board, but of the company which supplied it, although they were paid the highest price for laying it down, and for subsequent maintenance. The pavement was continued through New Oxford Street, as far as Tottenham Court Road, and it was considered at the time as fine a sample of wood pavement as had been laid in London proper.

(TO BE CONTINUED.)

ANNUAL REPORT OF THE SEWER COMMISSIONERS OF NEW LONDON, CONN.

THIS Commission was organized under State laws in April, 1886. The engineer of the Commission is Mr. Walter H. Richards, with Mr. R. Hering as Consulting Engineer.

The contract for the plan of intercepting-sewers was let in July of that year to Mr. M. S. Austin, and the work completed in February last, at a cost of about \$32,000, varying from 40 cents to \$3.25 per foot.

After a careful examination of all the property, and of the rules adopted in other cities, the engineer recommended the adoption of a plan of assessment based partly upon frontage and partly on area of lot assessed—six-tenths to area and four-tenths to frontage, with the following modifications: the area to be calculated to a line parallel with, and not more than 100 feet distant from, the street frontage. Frontage of corner lots may be exempted for a length of not over 100 feet, frontage to be assessed on the longer side, where both sides are less than 100 feet long each. Irregular lots dealt with specially.

The rates thus worked out were 50 cents per foot front, and 7 mills per square foot of area.

Three plates are given of details of wooden tidal-sewer, tide-gates, junction, etc. A description of this interesting sewer-work with illustrations was given in this journal, issue of March 19, 1887, page 401. Rules and regulations for plumbing, etc., are given in the appendix of the report; also, a full description of the work in progress.

THE SAND-BAR AT THE RAILWAY BRIDGE ACROSS THE RED RIVER AT SHREVEPORT, LOUISIANA.

THE report transmitted to Congress in March last is interesting as showing the difficulties to be contended with in crossing streams of this character. Contrary to what is usually expected, the general tendency for five years, as shown by the soundings on the axis of the bridge, was to fill over the whole line, so that Captain Willard reported in February last that five feet was the lowest stage at which the draw-opening was navigable. As the river is navigable for 300 miles above and 500 miles below the bridge, the matter is one of great importance, especially as the Government has spent considerable sums upon the navigation of the Upper Red River.

An examination of the United States statutes failed to reveal any law of Congress authorizing the construction of the bridge, and it was reported upon as subject to removal by process of law. Captain Bergland, of the Engineer Corps, suggested two plans for removing the bar: (1) By mooring barges above the bridge with movable plank sheeting extending to the bottom, so as to contract the current and scour away the bar; (2) to build low pile and plank jetties.

The act of Congress of July 5, 1884, gives power to the Secretary of War, and makes it his duty if he has reason or thinks it necessary,

"To require the company or persons owning, controlling, or operating said bridge to cause such aids to the passage of said draw-opening or of said raft-span, or of both said draw-opening and raft-span to be constructed, placed, and maintained, at their own cost and expense, in the form of booms, dikes, piers, or other suitable and proper structures for the guiding of said rafts, steamboats, and other water craft safely through said opening or span, or both said opening or span, as shall be specified in his order in that behalf," etc.

Under this law notice has been served upon the authorities of the railroad to take proper steps to remove the obstruction.

IRON-WORKERS IN EUROPE.

J. H. FLAGLER, the General Manager of the National Tube Works, was given a reception at McKeesport, Pa., recently, by the employees of the company, on the occasion of his return from Europe. Mr. Flagler made a speech to the employees on the result of his observations while abroad, in which among other things he said:

"I have seen people working for ten, twelve, and fifteen cents a day, and in some factories seldom obtaining above twenty cents a day. I have seen the same class of labor earning \$1.25 to \$1.30 in this country getting but thirty and forty cents. The same disproportion exists in the workers of metals in many places; and yet there are people in this country who call themselves friends of the workman and yet advocate a policy that would bring down wages to this same level. They don't seem to recognize that the conditions of this country are vastly different from those in Europe, climatic and otherwise. The same food would not sustain the wage-earner here, and other conditions as well make it necessary that higher and better rates shall ever rule in this country; consequently any policy advocated detrimental to your interests means a blow at the working class and the prosperity of the country."

ENGLISH PLUMBING PRACTICE.

BY A JOURNEYMAN PLUMBER.

No. LXIX.

(Continued from page 436.)

HOT-WATER CIRCULATION (CONTINUED).

SOMETIMES, as an economy, the return circulation-pipe has been of a smaller size than the flow-pipe. For instance, a $1\frac{1}{4}$ -inch flow-pipe has been fixed from the cylinder to the furthest point away and an inch pipe carried back to the cylinder. This is not a good plan, as reducing the size of the pipe causes, by the extra friction of the smaller pipe, a sluggish circulation of the hot water. In addition to the extra friction of the water in the smaller pipe there is also, proportionately, a larger radiating surface and consequent loss of heat, so that for these reasons it is advisable to have the circulating-pipes of the same bore throughout. Another view of a small return-pipe may be mentioned—viz., the smaller the pipe the larger proportionately is the radiating surface, so that the temperature of the return-water is much more reduced, and theoretically this ought to cause the water to circulate more freely.

In some cases the hot-water cylinders are fixed horizontal instead of vertical.

Figure 1 is a sketch diagram of a cylinder fixed horizontal and the circulation-pipes, as recently fixed under

also for heating corridors or rooms by radiators is a good one, as it is almost impossible to keep one constant heat.

In some instances a hot closet has been fixed in a kitchen, for warming plates and dishes, and connected with the boiler circulation-pipes. For want of the proper knowledge some of these have been found to be failures. The writer had to inspect one that had been fixed but a few months, but no matter how hot the water was in the boiler the closet was always quite cold.

Figure 2 shows the arrangement. The man who fixed it said he would give it up and own he was beaten, but when asked if water or air was in the coil Z, he at once saw where he had made a mistake. He then made the necessary alterations so as to allow the pent-up air to escape from the highest end of the horizontal coil. Acting on advice, he also connected both ends of the horizontal coil to the flow-pipe from the boiler and put a small perforated disk of copper at Y so that the water did not circulate past and miss the T-junction. This air-binding of pipes is of frequent occurrence and in a great variety of ways. In a row of six mansions a stupid blunder was committed in each house. The storage capacity for cold water was too little, with the result that the cisterns would frequently get emptied. Every time the cisterns were emptied and filled again, it was found impossible to draw water at the hot-water taps. The reader is referred to Fig. 3, which shows what was found. The cold-water supply to the boiler was connected to the bottom of the cistern, and, about six feet away, the pipe was lifted about two inches, so as to fix it with a pipe-hook to the wooden bearer on which the cistern was placed. On taking out the hook in each house, and lowering the pipe, air came bubbling back into the cistern, after which the water ran freely into the boiler, and could be drawn at the various taps. It may be further explained that the bottom end of

wide apart. No matter how many sets of circulating-pipes are fixed, it is always necessary to have a vent-pipe from the highest end of each to allow the air to escape. In some cases a draw-off pipe has been fixed near the highest end, on opening which any air could escape, but this is not by any means a good system to adopt. When air-pipes are fixed, it is scarcely necessary to add they must be carried to a level above the cold-water supply-cistern.

A reason was given in an earlier paper for connecting the return-pipe to the cylinder, instead of branching it into the boiler or the cold-water service-pipe to the boiler. To prevent water from being drawn from the return or cold, instead of the flow or hot-water pipe, some makers will fix a small flap-valve, inside the circulating-pipes, that opens in the direction of the flow of water when circulating, but closes should the circulation by any means become reversed, or to prevent back-water being drawn when a tap is opened for drawing hot water.

A great many hot-water men fix stop-cocks in the circulation-pipes, but this practice cannot be too strongly condemned. A few years ago a serious accident (?) occurred through this. The stop-cocks were closed while a new draw-off cock was being fixed, and it was forgotten to reopen them, with the result that when the fire was lighted the water in the boiler expanded sufficiently to burst it.

Elbows in circulation-pipes should always be avoided as much as possible, it being much preferable to have bends of an easy sweep or radius. Some first-class men will always insist on the pipes being heated and bent to suit the various positions, instead of using those bought at the manufacturers, the reason being that every bend, especially when made to a small radius, causes a retardation of the free flow of water, and as the force in the form of heat, which puts the water in motion, is very small, all obstructions and unnecessary friction should be avoided as much as possible. When galvanized-iron pipes are heated and bent the zinc coating is melted off. For common work no notice is taken of this, but for best work the pipes are bent first and galvanized afterwards. When done this way the bends should be carefully examined, as they have sometimes been found to be partly or entirely choked with zinc. Some men who take a pride in their work will make very nice bends, and when two or three are fixed together will make them match, so to speak, as shown at Fig. 4. Figure 5 is an elbow drawn for comparison with the bends. Mention has been made of the expansion and contraction of hot-water pipes. If no allowance is made for this motion of the pipes the result will be that some of the joints will leak, and this occurs more especially with long straight lengths. As expansion and contraction are, to a certain extent, irresistible forces, it follows that provision should be made to allow for them. The introduction of bends, as shown at Fig. 4, will allow for a great deal of motion of the pipes, and is a very simple and easy way of overcoming the difficulty. Figure 6 is a gland joint that can be used for the same purpose, the lining sliding in and out of the gland-box.

Figure 7 is, I think, an American invention and appears to be a simple and easily applied expansion socket, but not having used them the writer does not know how long they will last without breaking. But perhaps they are made of very tough but flexible iron and are as strong as the other parts of the fittings. In addition to expansion-joints it is important that the circulation-pipes should not be fixed by any branches, but this was referred to when writing on lead-encased tin pipes.

When hot-water pipes are fixed round and inside a room, they should not be too tightly fixed at the return ends, but should be kept at least one inch clear of the walls. Figure 8 explains what is meant, the dotted lines showing how the pipes will bulge out in the centre portion when expanded by heat. If the pipes are fixed clear of walls, as suggested, this would not occur, as the expansion would be expended at the ends. Neither should the pipes be too rigidly fixed by means of wall-hooks. Horizontal pipes should lay on brackets, which, although supporting, will not prevent them freely moving backwards and forwards. Lead pipes should lay on wood fillets, as stated in an earlier paper. Figure 9 is a neat brass or gun-metal bracket which can be screwed to a wooden block or lining board fixed to the walls. Long vertical pipes should be supported in the centre of the length, so that the expansion may be equally distributed at the ends.

(TO BE CONTINUED.)

the supervision of the writer. In the sketch, A is the cylinder fixed on brackets over a doorway; B is the boiler; C C C are taps over the scullery, servants' hall and butler's pantry sinks; d d are taps over lavatories; e is fixed to supply hot water to the housemaid's sink on chamber floor, and f to the spray and plunge bath; g is a coil for heating the bath-room, and is arranged so that towels, etc., can be dried or warmed; h is a coil on upper floor to warm a water-closet room and adjacent lobby. The waste heat is made use of by carrying the return-pipe through the housekeeper's room and the linen-room, the pipe being bent to form a radiator, as shown at j. It will be noticed that all the draw-off taps are branched into the flow-pipe, which is carried as direct as possible, and the coils or radiators are connected beyond the furthest tap so that the water may be drawn as hot as possible at the taps. The coils are so attached to the circulating-pipes that by closing three or four stop-cocks the water will flow round without passing through the coils, heat not being wanted in the rooms in the summer time. K is the cold-water supply-tank, and the service to the boiler is shown by dotted lines. The whole arrangement works very well. In this, and similar cases, it was found that after drawing sufficient hot water for a bath the heat from the coils fell considerably and some little time had to elapse before they got hot again. For this reason it is an open question if the pipes, etc., for supplying hot water to sinks, etc., and

the supply-pipe was sealed by the water in the boiler so that the air could not escape or be driven out at the bottom, although the cold-water cisterns were about sixty feet above the boilers. Great numbers of similar blunders could be given, but the writer does not consider it necessary to weary his readers by repetition of cases.

A common cause of complaint is that such a quantity of cold water has to be run to waste before hot water can be had at the taps. This occurs chiefly with long branch draw-off pipes to taps some distance away from the circulation-pipes. In a great many cases it is possible to fix return-pipes to these branches so that the water will circulate through them and thus avoid the evil referred to. Where it is impossible to circulate through the branches, the size of the pipes should be reduced as much as possible, so that less water will have to be run to waste. This applies more particularly to wash-hand-basins, where only a small quantity of hot water is required. For baths it is not so important to reduce the size of the pipes, as a few pints, or even a gallon, of cold water having to be drawn does not much matter, but if the pipe is reduced, the bather's patience would perhaps be exhausted by waiting for the bath to fill from a small pipe. In some cases it has been found to be an advantage to have two, or even three, sets of circulating-pipes carried from the cylinder to the various parts of a house, especially when the shape of the house is large and straggling, and the draw-offs are

EXAMINATION OF PLUMBERS IN WASHINGTON.

(From an Occasional Correspondent.)

WASHINGTON, D. C., September 20, 1887.

HAVING seen no report in THE SANITARY ENGINEER AND CONSTRUCTION RECORD of the operation of the revised regulations governing the registration of plumbers in the District of Columbia, I send you the following abstract of facts in the matter, in the belief that they will be of interest to plumbers who read your paper and to municipal officers.

The Board for the Revision of Plumbing Regulations and the Examination of Plumbers was appointed by the District Commissioners on April 6, 1887. It consisted of the following members: Samuel A. Robinson, Inspector of Plumbing (Chairman); H. F. Hayden, Superintendent of the Water Department; Dana C. Barber, Inspector of the Water Department (Secretary); R. G. Campbell, President of the regular Master Plumbers' Association of the District; and A. S. Dent, President of the Master Plumbers' Mutual Protective Association. The first work was the preparation of rules for the registration of plumbers, which, after revision by the Engineer Commissioner, were promulgated on April 23, as published in THE SANITARY ENGINEER AND CONSTRUCTION RECORD in the issue of April 30, Vol. XV. A supplementary regulation required the payment of a registration fee of three dollars. The time for the registration of masters was to expire August 31.

The number of applications during the first three months was comparatively small, only thirty-five out of over 100 known to be engaged in business in the District, and most of these were of the more intelligent of the craft, so that only four were rejected, though it is the general belief among the plumbers that those who "went up" first had an easier time than the late comers.

Previous to the first of August only one meeting a week was held for examinations. Usually not more than three candidates were examined—frequently four, but never more than six—at a single session lasting nominally from 7:30 to 9 P. M., but frequently prolonged till 10 or even 11 o'clock. Each candidate was examined separately, with no others present. In making appointments, a half-hour was usually allowed to each, but this time was frequently extended, sometimes to more than a full hour, especially when there were but one or two candidates at a session.

The examinations were wholly oral, excepting simple blackboard sketches, mainly for illustration. The questions were both on theory and practice—design and workmanship—and varied in each case from every other, no regular form being followed, though of course the same question was often asked different candidates.

Some of the more common points of deficiency were: The cause of the circulation of air through the house-drainage system; the effect of wind blowing across the tops of soil-pipes and fresh-air inlets; the grade for the main drain; methods of supporting soil-pipes; size of trap-pipes and the effect of sharp bends in the same; methods of trapping area drains, and construction of joints in cast-iron and earthenware pipe.

As the less intelligent men came up, late in the season, it was found that many skilled and honest workmen were too deficient in elementary physics to pass satisfactorily, and in such cases the board recommended that the candidate's application be refused, but that he be allowed to continue in business (if he was already in business) for three months (the required interval before a second examination is allowed), in the belief that in that time he would qualify himself—and the Commissioners in all cases approved such recommendations.

In August the board held meetings for examination nearly every night, and fifty-two applications were disposed of. At the end of the month (expiration of the limited time), sixty-four had been authorized to register, fourteen rejected but allowed to continue in business during the required interval before a second examination, and ten rejected absolutely, of whom two were not called for examination, being unable to read or write, and one rejected without examination, for appearing in an intoxicated condition. One who early in the season failed to pass satisfactorily, tried it again after three months of hard study and was successful.

As many plumbers known to be carrying on the business had not applied for examination, while many who had

passed successfully had not registered, the Commissioners extended the time for registration to September 10, and ordered that after that date no permits be issued to unregistered plumbers.

At the close of office hours on the 10th the record stood: Applications, 97; authorized to register, 67; rejected, but allowed to continue three months, 17; rejected absolutely, 13; registered, 54.

At this date nearly all who have been authorized to register have done so, but few new applications have been presented. There remain, perhaps, a dozen master plumbers who have not applied for examination. They are preparing, it is said, to contest the legality of the regulations, together with some who have been rejected.

Applications were frequently made to the chairman early in the season for information as to the best books to study in preparation for the examination. Of the several recommended, I suppose none was so generally bought and eagerly studied as your "Plumbing and House-Drainage Problems."

The revision of the plumbing regulations has not yet been completed, nor has the examination of journeymen been inaugurated.

Correspondence.

All correspondents should send us their names and addresses, not necessarily for publication, but as a guarantee of good faith and because it is often necessary to communicate with them for additional information before printing their communications. Anonymous letters will not be noticed.

USING OIL OR GAS UNDER BOILERS.

WASHINGTON CITY, September 17, 1887.

SIR: I have a No. 4 Dunning boiler, low-pressure steam (agents, Littel & Co., 40 Cortlandt Street), and want to use gas or petroleum for fuel instead of coal. I have written to several parties, but have not got exactly what I would like. I have written to-day to a number of advertisers in THE SANITARY ENGINEER AND CONSTRUCTION RECORD, but think it best to write you to ask if you know of any such arrangement, and address, or any book on the subject. I have your books on steam-heating and plumbing hints. Do you think your correspondent "Thermus" could assist me? If so his name and address or that of any one that you think could aid me. I want to make the test at once before I put plants in my house (October 15). I will be obliged for any assistance you can give me as soon as possible. Yours truly, WRIGHT RIVES, P. O. Box 279.

[If our correspondent desires to burn gas under a boiler we must refer him to the methods pursued by the users of natural-gas at Pittsburg and vicinity, which appeared in our issue of January 15, 1887.

With regard to the use of oil we know little, though there are several burners in the market for this purpose that can be introduced into a boiler furnace and lay on the grates. Oil and air are introduced through different openings, and a recent patent on this subject is on the principle of the fuel cartridge, the oil being fed through the porous material from a reservoir and air admitted between the rings.

"Thermus" informs us he has had no experience with oil, and with gas his knowledge is limited to the use of natural-gas.

Presumably, some of our readers may be able to send Mr. Rives their experience in the use of gas and oil, and we would suggest correspondence with the makers of the boiler—N. Y. Central Iron-Works, Geneva, N. Y.]

WARMING WATER FOR BATHS IN SOLDIERS' BARRACKS.

OFFICE OF THE ACT'G ASS'T QUARTERMASTER, } WILLETS POINT, N. Y. HARBOR, September 23, 1887. }

SIR: Will you kindly tell me where I can get a simple and cheap water-heater that could be placed in soldiers' barracks, connected with water system (pressure in main sixty pounds), to heat water for bathing purposes, etc.? It is to perform the same office as the water-back and reservoir attached to a range for supplying hot water to plumbing fixtures in houses. Very respectfully, IRVING HALE,

First Lieut. Engineers, A. A. Q. M.

[It is not clear to us whether our correspondent intends to use the heat of a fire or the heat of steam for warming the water.

If the heat of fire is intended, he may use any of the small hot-water boilers used for warming purposes and connect it with either a closed or open tank, so as to circulate in the ordinary manner. If an open tank is used a ball-cock must be used within it to keep the water-level

constant and the tank should be as high up as possible, as only the pressure from this tank will be exerted at the faucets.

If a closed tank is used, it can be placed a few feet above the boiler, using good large circulating pipes, and the pressure of the water-works maintained upon it. Some of the makers of hot-water boilers make a small apparatus for use with an ordinary kitchen boiler.

If the heat of steam is to be utilized, the custom in New York among steam-heating firms is to provide a closed tank, say three feet in diameter by five or six feet long, with a manhole and cover in one head. It may be of ½-inch thick iron, with ¾-inch or 1-inch heads, and requires no bracing if only for sixty pounds water-pressure. This can be purchased for about \$90 of a boiler-maker.

Within this tank place about four turns of 2½-inch brass pipe, with brass bends to form a coil, bringing the ends through the head of the tank opposite to the manhole and fastening them with lock-nuts. Use exhaust-steam in this coil if you have it to spare; if not, use live.

It is a good method to fit the coil up for the use of either live or exhaust steam, using the latter when you have it and turning on the live at other times.

The addresses of a number of makers of hot-water heating boilers will be found in our advertising columns.]

STREET SWEEPINGS AS A FERTILIZER.

FLUSHING, L. I., September 20, 1887.

SIR: In a late issue of your paper an inquiry was made in regard to the results of the application of street sweepings to land. For the last fifty years it has been used on Long Island for all kinds of crops, and is considered about equal to horse manure, that collected from streets downtown (New York) being the best. It is excellent on light soils and should be spread broadcast after plowing and harrowed in. It is very good as a top dressing for lawns and meadows. It costs, delivered by boats to nearest dock on Long Island, about \$1 per two-horse wagon load.

Respectfully, F. R. S.

Novelties.

Under this heading we propose to describe and illustrate appliances of probable interest to our several classes of readers. The selection will be made without reference to the wishes of agents or patentees, being governed solely by considerations of novelty, ingenuity, and probable interest to readers, and especially the fact that they have not been elsewhere described. As a rule we shall make no comments, and it is to be distinctly understood that a notice does not imply approval. No charge will be made for these notices, and any offer of pay for their insertion will insure their omission. We shall be glad to have our attention called to novelties suitable for this section.

STEAM-RADIATOR AIR-VENT.

THE accompanying sketch illustrates a novel method, just patented by Gordon W. Lloyds, architect, of Detroit, Mich., for preventing the escape of water through the air-vents of a steam-radiator.

It consists in a float being introduced into a vertical pipe of the radiator, to the upper end of which there is a disk attached by a spring or suitable elastic substance. This disk conforms to a seat, within a plug or suitable equivalent, at the top of the pipe, thus forming a valve. Should water rise within the radiator from any cause, the float lifts the disk and closes the valve, thus preventing an overflow.

In this same plug or cap, at the head of the pipe, the air-cock is also placed, and the prime object of the invention is to stop the escape of water from the air-vent, should the latter be forgotten, or should it be opened while the radiator was full of water.

The expansion of the float-cylinder—which is made of a metal with a greater coefficient of expansion than iron—is also taken advantage of to close the escape against steam when the air has been driven from the pipes.

CHAIN-TONGS.

THE accompanying sketch shows a novel improvement in chain-tongs for screwing or unscrewing pipe lately patented by

William Gormesly, of Chicago, Ill.

The apparatus consists of a lever, with the usual serrated end to engage the pipe, and a chain to wrap about it, and wherein it differs materially from the ordinary chain-tongs is in having a movable collar on the lever to which the chain is attached at the back by an eye and in the front in the usual manner between two prongs. The invention consists in the adjustment of the collar on the lever, the object being to secure finer adjustment of the chain about the pipe than can be

obtained by moving it the length of one link. Its use is obvious to a pipe-fitter.

GAS-PIPE PIERCING MACHINE.

THE *Engineer* thus describes a machine for punching holes in gas-pipes for illuminating devices, for which there was a great demand for the recent jubilee:

"With a view to the large quantity of work which will be required for the general illuminations of this month, the piercing machine illustrated below for perforating the

copper tubes for making gas-illumination devices will be of interest to many readers. It is not only a labor-saving, but what is more important in these matters, a time-saving contrivance. The holes made by it are, moreover, regular in size, and are all pierced straight and true."

It is made by Messrs. Winn & Co., of Birmingham.

ANNUAL REPORT OF THE BOARD OF PUBLIC AFFAIRS OF CINCINNATI.

THIS report covers that of H. J. Stanley, Chief Engineer, and his assistants, T. A. Ridgway and A. E. Tripp. The expenses for salaries in the Engineering Department were \$38,531.67, and for office expenses, horse hire, etc., in same, \$6,358.

The total cost of works completed during the year 1886 was \$1,161,971.62, and the estimated cost of works projected, \$2,078,755.81, the total being largely in excess of the work of any previous year.

The sewers built during the year were less in length than the average, being 2 1/8 miles, making the total length of sewers now laid to be 47 1/2 miles; 818 sewer connections were made during the year.

The total miles of gas mains in the city is nearly 256 miles, and the average cost of gas per lamp for street lighting for the year was \$22.54, and for 1,000 feet of gas for the same, \$1.1244; this is about two-thirds only of the average for the five cities—New York, Pittsburg, Baltimore, Louisville, and New Orleans, the average by months for New York being \$1.72. Gasoline lamps cost by the year \$24.14 each, 1,314 being in use.

E. G. LOVE, Ph.D., Gas Examiner.

THE largest gas-receiver in Germany, which will hold 50,000 cubic metres of gas, is that at Grasbrook, and cost 814,000 marks. It was designed by Herr C. Haase, of Hamburg, who gave a description of the receiver before a recent meeting in Hamburg of the German Society of Gas and Water Works Men.

CORROSION OF METALS.

CONSIDERABLE difficulty is experienced by mining engineers in procuring metal which will not easily corrode in contact with the acid waters in mines. Experiments have been made in Germany with various metals, among others being Delta Metal, as manufactured by Mr. Alexander Dick, of 110 Cannon Street, London. We are informed that the Bonifacius Coal Mining Company of Westphalia, had great trouble in this respect owing to the acid waters quickly corroding the iron and steel of the underground machinery, therefore they determined to make a series of experiments with the view of finding the relative corrosion

CORROSION OF METALS

of metals of suitable strength. Brass and gun-metal were not strong enough, and hence they had trials with steel, iron, and Delta Metal. Rolled bars of each of these were immersed during a period of six and a half months in the water issuing from the pits at Kray, and then carefully re-weighed and photographed. The bars were 7.5 inches long and had a sectional area of 0.62 square inch. We give weights of three kinds of bars before and after the trial and the condition after the tests is shown by the accompanying engravings. In consequence of the rapid corrosion of iron and steel, Delta Metal is now used instead for underground machinery in this and other mines.

	Wrought Iron.	Steel.	Delta Metal.
Weight of bars when put in.	lb. 1.1805	lb. 1.2125	lb. 1.2787

—The Gas Engineer.

A LESSON TO BRIBERS.

MR. WILLIAM F. TAFTE, one of the recently appointed inspectors of plumbing under the New York Board of Health, has rendered a public service and taught bribers a wholesome lesson in securing the arrest of two men who sought to bribe him to pass some defective work. Mr. Taffe, when approached, reported the fact to the Department and was referred to Police Inspector Byrnes, who instructed him to receive the money and mark it in order that the bribers might be identified. This was done and these men, Barrett Harris and Bernard Bloomberg, were arrested. The board, at its meeting this week, passed resolutions thanking Mr. Taffe for his plucky conduct in the matter. He certainly deserves commendation, for it requires more pluck to expose men of this sort than it does to refuse the bribe, and his action will no doubt have a wholesome effect in this city; at any rate, it will teach a certain class of men that every man that holds a public inspectorship is not necessarily venal.

EIGHTH ANNUAL REPORT OF THE BOARD OF HEALTH OF THE CITY OF ATLANTA FOR THE YEAR 1886.

THE vital statistics of Atlanta do not appear to be satisfactory as to accuracy and completeness. The board estimate the annual death-rate among the whites at 10.10 and among the colored at 23.71 per 1,000. Evidently either the population of the city is much overestimated or a considerable number of deaths are unrecorded, for it is so extremely improbable that the death-rate of the white population in a city like Atlanta should be less than 16 per 1,000 that any less rate should at once lead to doubt of the figures employed.

The sewerage of the city is still under consideration, and the board recommend that Mr. Ernest W. Bowditch, of Boston, be employed to prepare plans.

It also advises the enactment of a set of plumbing regulations. The reports of the inspectors show that a large amount of garbage and night soil has been removed during the year, and that good work has been done in the suppression of nuisances. The total cost of the Health Department during the year was \$23,818.45.

SYRACUSE HEALTH OFFICER'S REPORT.

THE first paper in the third annual report of the Board of Health of Syracuse, N. Y., is the report of the Health Officer, Dr. John Van Duyn. After remarking that the vital statistics of the city are incomplete, but that steps are being taken to make them more satisfactory, he gives the death-rate for the past year at 15.57 per 1,000. This is a very low mortality—suspiciously low, in fact. Of the 1,059 deaths reported, 176 were due to consumption, 18 to diphtheria, and 34 to typhoid fever. He states that "a comparatively small part of the city uses the water supplied by the water company. The supply does not reach far beyond the central low-lying districts of the city." The sewerage system is declared to be in a rude and undeveloped state and without satisfactory ventilation. The bad condition of Onondaga Creek, which is practically an open sewer, is referred to, and the city government is warned that it is in danger of creating a similar nuisance in Harbor Brook. Dr. Van Duyn says: "Most houses here are built on speculation, and the principle which rules the construction of the drainage is concealment of evil and economy of expenditure. In all cases that came under my observation nearly every principle of safe construction was violated; too large and porous pipes, straight pipes set in sharp angles, insufficient cementing of joints, poor, cheap, and insufficient traps, no ventilation, etc.; so that when the houses were completed they became at once sources of danger to the inmates."

The report of the Health Inspector, W. H. Pohlman, shows that 15,863 loads of garbage were removed during the year, and that 3,442 nuisances of various kinds were abated. He remarks that "the greatest evil that exists in our city is the great number of privy-vaults and cess-pools, the contents of which leach into and contaminate many wells."

The total expense of the removal of garbage for the year was \$16,579.57, and the amount received from its sale was \$232.50.

The report shows that the Health Department has been active, and that there is plenty for it to do in the near future.

THE AMERICAN MACHINIST.

OUR valued contemporary, the *American Machinist*, announces that Fred. J. Miller, a mechanic and engineer of recognized ability and a former contributor to its columns, has relinquished an excellent position in a large manufacturing establishment to accept a position on the editorial staff of that paper. Mr. Miller will devote his entire time to the mechanical department.

THE ARCHITECTURAL LEAGUE PRIZE COMPETITION.

THE Architectural League announces that it has instituted, in connection with its exhibition, an annual competition, open to all draughtsmen in the United States under the age of twenty-five. The object of such competition to be the promotion of good design and the improvement of draughtsmanship.

As prizes, it offers to the design placed first, a gold medal, to be known as The Gold Medal of the Architectural League; and to the design placed second, The Silver Medal of the Architectural League.

The conditions for admission to the competition are:

First—That the competitors shall be residents of the United States, and under the age of twenty-five; and—

Second—That the drawings shall be made in conformity with the following programme, and, in all parts and portions, entirely by the hand of the competitor.

The drawings will be judged by a jury appointed for that purpose.

The successful drawings, and such others as may be thought worthy, will be hung at the exhibition, the first and second prize drawings being so indicated, and these latter shall thereupon become the property of the League.

The following is the programme:

The drawings shall exhibit a "Memorial Clock and Bell Tower on a Village Green."

The tower to stand on a base which shall not exceed the dimensions of a square of twenty-two feet.

Each contributor to exhibit two sheets of drawings: one to contain plans and elevations at the scale of four feet to the inch, and one to exhibit a perspective view. The plan and elevation sheet to be finished in line with India ink and the lining pen. No brush-work on this sheet, except in blacking in windows and sections. No shadows are to be cast. The perspective sheet to be rendered at will. Each sheet to be cut to the uniform size of 24 by 32 inches, and to be white card or Bristol board, or Whatman paper, mounted on stretcher. No colored borders, frames, or glazing will be allowed.

Each sheet must be distinguished by a motto or cypher. A sealed envelope, bearing the same motto or cypher, must contain the name and full address of the author.

Drawings are to be delivered flat, carriage paid, on or before December 5, 1887, to Charles I. Berg, Secretary, 152 Fifth Avenue, New York City. They will be returned at the close of the exhibition at the expense of the contributor.

Messrs. William C. Hazlett, John L. Dufais, and Charles I. Berg are the Committee.

Further information may be obtained by addressing Charles I. Berg.

KANSAS CITY CHURCH COMPETITION.

THE design over motto "Black and White," of Mr. Adriance Van Brunt, of Kansas City, Mo., has been placed first in the competition for the new Grace Church in that city.

ENGINEERS' CLUB OF PHILADELPHIA.

A MEETING was held June 18, President T. M. Cleemann in the chair; 11 members present.

From record of last meeting, held June 18, we learn that members were elected as follows:

Active Members—Messrs. W. H. Frances, P. Doyle, John C. des Granges, and Francis W. Whiting.
Associate Members—Messrs. Robert Neilson and Horace B. Powell.

The following resolution was unanimously adopted: *Whereas*, The club has examined United States Coast and Geodetic Survey Chart, No. 3694, of the Hudson and East Rivers in the vicinity of New York, scale 1:100,000, with a view of considering the value of a proposed similar chart of the Delaware and Schuylkill Rivers, near Philadelphia; *Resolved*, That the club is highly pleased with this form, arrangement, and scale, and have no amendments or

changes to suggest, and believe that such a chart of the Philadelphia rivers would be of great value to the profession and the public.

Mr. John L. Gill, Jr., presented a description of a new system of screw threads which he had arranged, and asked that a committee be appointed to examine and report upon the same. The president appointed the following committee: Messrs. Henry G. Morris, Chairman, John T. Boyd, Professor L. M. Haupt, Washington Jones, and M. R. Mucklé, Jr.

The secretary presented, for Mr. E. L. Cortbell, an illustrated account of a Venetian ship railway.

For Mr. C. H. Middleton, Jr., an interesting letter descriptive of camp life on the Union Pacific Railway Surveys.

For Mr. R. Meade Bache, an illustrated description of a boat telemeter.

Mr. S. P. Mitchell presented an illustrated description of the Susquehanna River Bridge of the B. & O. R. R.

Howard Murphy, 1,122 Girard Street, Secretary and Treasurer.

RIVER AND HARBOR IMPROVEMENTS IN MASSACHUSETTS AND RHODE ISLAND.

MAJOR W. R. LIVERMORE, in his report to Chief of Engineers, submits an estimate for next year's expenditure at Hyannis, Mass., of \$35,662; at Nantucket, \$50,000; at Wareham, \$16,236; for Pawtucket River, \$50,000; and for Providence River and Narragansett Bay, \$100,000. Of Newport Harbor he says the objects of the improvement are to widen and deepen the southern (main) entrance, enlarging its capacity for vessels seeking refuge in storms by increasing the area and depth of anchorage. In dredging the harbor and widening and deepening the entrance, \$42,000 have been expended, and \$52,000 is the sum estimated to be necessary to complete the projected work, of which \$30,000 can be profitably expended next year. For next year's operations at the Harbor of Refuge at Block Island, \$53,189 is asked; \$33,000 for Stonington Harbor, and \$26,637 for Pawtucket River. The importance of the work at Harbor of Refuge at Vineyard Haven is set forth. Estimates amounting to \$3,983,936 are submitted.

M. EIFFEL, the projector of the Tower of Babel for the Paris Exhibition, is no novice in the matter of huge engineering constructions. He made the framework of Bartholdi's "Liberty," and executed the grand vestibule and the principal facade of the Paris Exhibition of 1878, a work which came to three million francs. One of his principal works is the bridge which he erected over the Douro at Oporto, on the Lisbon Railway, in 1876, which is, indeed, one of the finest specimens of engineering skill in Europe. The river is spanned by a magnificent arch of 160 metres at a height of 61 metres from the river, and is executed with a view to the artistic effect as well as its stability. This bridge cost a million and a half francs. Another remarkable work of M. Eiffel is the railway viaduct of Parabit, over the valley of Truyère, in the middle of France, which cost 3,248,000 francs. Here the opening of the arch is 165 metres, and the height above the water 124 metres. He has also constructed some railway bridges and viaducts remarkable for their length, such as a bridge at Szeged, in Hungary, which is 606 metres long, and one at Vianna, in Portugal, which is 736 metres. —*The Architect*.

POSTAL TUBE BETWEEN DOVER AND CALAIS.

M. A. ARNAUDEAU, a French engineer, proposes to construct a postal tube of sheet iron between Dover and Calais, to be suspended from pillars 800 metres apart.

The tube is to be one metre in diameter, and to contain a little railroad on which a train of from 10 to 15 cars, each weighing when loaded 500 kilogrammes, is to be driven by a pneumatic tube. The piers and pillars are to be constructed to carry four such tubes, and the greatest depth of water in which any one of them will be placed is estimated at 60 metres. Each tube with its contents is to weigh 125 kilogrammes per metre of length, the total length being 32 kilometres. The pillars from which the tube is suspended are to be of iron trellis-works and to rise 110 metres above the water. The total cost is estimated at 25,000,000 francs.

THE PARIS SCHOOL OF FINE ARTS.

ARCHITECTS will be interested in the article under the above title by Henry O. Avery in the *Scribner's Magazine* for October. Among the seventeen illustrations are portraits of five of the professors.

FOURTH ANNUAL REPORT OF THE TRUSTEES OF THE FREMONT, OHIO, WATER-WORKS.

This report contains just enough information about the water-works to make us wish for more. It appears that a portion at least of the supply is derived from ground-water collected by tile-drains laid in a bed of saturated gravel. It is not stated how deep these pipes are laid, nor what their total length and the area of the gathering ground are. It is stated, however, that a recent addition of 2,530 feet of 6, 8, and 9 inch tile did not materially increase the yield, as the water-surface in the gravel has been lowered. This looks as if the demand had already outgrown the yield of the gravel. In February and March the gathering ground was overflowed and the water furnished was turbid. This looks as if the pipes were not laid deep enough.

There are 275 taps, using 359,665 gallons a day, or 1,308 gallons per day per tap. This is very much in excess of what is really needed and is extravagant and expensive.

The water is pumped into a stand-pipe, a cut of which is given, but its height and size are not given, neither is there any information as to the size of pumps used. The fuel used is coal, natural gas, and crude petroleum. The latter is used with atomizing spray burners, and the engineer, Mr. C. F. Reiff, thinks that it is more economical than bituminous coal.

The Secretary, Mr. Joseph Schwartz, reports the cost of maintenance for the year as \$3,690.15 and the revenue \$5,217.

The works have cost \$143,854.69.

CAPTURE OF A BOA IN A SEWER.

SOME sewer men met with a strange adventure while at work one night in one of the labyrinths of subterranean Paris. As they were busily engaged in cleaning out that part of the metropolitan cloaca which is under the Boulevard de la Villette, they suddenly hear a loud and prolonged sound of hissing, which some of them took to be the cries of a person in distress, who had, perhaps, fallen into the drain at one of the open points. Redonnet, the foreman of the gang, thought, however, that the strange noise was caused by evil doers, who were probably hiding in the sewers from the police; so he took up his shovel and marched boldly toward the spot whence the sounds proceeded. After having proceeded a considerable distance, he saw by the dim light of the sewer-lamps an enormous boa constrictor coiled around one of the water-ducts, with its head protruding toward him. Redonnet immediately stunned the reptile with a vigorous blow from his shovel, and, his workmen having come up, the whole party set to work until they battered the life out of the ill-fated and imprudent boa. The remains of the reptile were then carefully collected and borne in triumph to the surface of the earth, and then to the nearest police station, where, it appears, the boa was "wanted," as it had managed to escape from the menagerie of a wandering showman, who had been exhibiting his "fearful wild fowl" to the inhabitants of the municipal boroughs of La Villette and La Chapelle.—*N. Y. Times*.

LIME-KILN CLUB SANITARY ITEMS.

(From the *Detroit Free Press*.)

THE Secretary of the State Board of Health of Illinois wanted to know what progress, if any, the colored people of Michigan were making in sanitary matters. Brother Gardner said he would like a general discussion of the subject, and Sir Isaac Walpole arose to remark that he was making progress. Up to a year ago he didn't know that seven persons and a dog sleeping in an 8x10 room with all the windows down and the doors closed was injurious to the human system. He supposed the feeling of languor was brought on by non-circulation of blood in the feet.

Whalebone Howker had also progressed. He had now learned the difference between the smell of gunpowder and sewer-gas, and the lives of his thirteen children were no longer in peril.

Pickles Smith used to wash his feet once in six months. Now he felt conscience-stricken if a week passed over his head that he didn't heat up a boiler of water and soak up his pedals. His five dogs used to sleep in the house. Now they either made their beds in the doorway or stood up against the wood-shed door.

Judge Chewso had slept in a room with six other persons, a barrel of soft soap, three dogs, an old codfish, and a limburger cheese, but he had progressed. He used to wake up in the morning and charge the Democratic Party with seeking to poison him, but now he realized that it was his ignorance of sanitary precautions.

Several other members spoke in the same strain, and related vivid personal experiences, and the president finally said:

"De secretary will answer to de effect dat we ar' improv'in' in sanitary matters in de rapidest manner, an' dat de time am party nigh at hand when a black pusson sleepin' in de garret of a house doarin' de hot nights of July an' August will werry probably remove de feather bed an' dispense wid about fo' comforters."

PERSONAL.

G. W. F. SHERWIN, C. E., who made the survey of the Northern Missouri Railroad and laid out the towns of Sioux City and Niobrara, Neb., died last week at Erie, Pa. Mr. Sherwin was Water Commissioner of Erie.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITIONS.

THE time for receiving the plans and specifications for a building on John and Jackson streets, Hamilton, Ont., has been extended from September 15 to October 12.

A. S. DRAPER, State Superintendent of Public Schools of New York, under authority of an act of the last legislature, offers \$975 in prizes for best designs for school-houses, cost not to exceed \$600, \$1,000, \$1,500, \$2,500, \$5,000, and \$10,000 respectively. Full particulars can be obtained by addressing Professor Draper at Albany, N. Y. A committee, consisting of ex-State Superintendent W. B. Ruggles, Professor J. W. Kimball, Superintendent Charles E. Gorton, Principal E. H. Cook, Dr. G. A. Bacon, Willis R. Hall, and Albert W. Fuller, architect, will examine the designs and designate the two in each class which in their judgment possesses the most merit.

ENGINEERING COMPETITIONS.

ENGINEERS and contractors are asked to furnish plans and specifications for the construction of the work necessary to the straightening and changing of the channel of the Rio Grande River, and the building of a levee at and near Alamosa, Colorado, until 12 o'clock M., October 15. For further information address J. S. Greene, Secretary Board of Construction, Denver.

ESTIMATES are wanted until October 20, from civil engineers, for surveying about 64 miles of railroad with about 40 miles of extra survey at Hayneville, Alabama. Bids must not exceed \$900. References will be required. For further information address W. Brewer.

For works for which proposals are requested see also the "Proposal Column," pages 477-481-483-484-497.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE SANITARY ENGINEER AND CONSTRUCTION RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

WATER, SEWERAGE, ETC.

MT. CARROLL, ILL.—See our Proposal columns for information respecting a system of water-works to be constructed here.

HASTINGS, NEB.—The sewerage question is still unsettled, and experts are now considering the matter.

SAVANNAH, GEO.—Dissatisfaction is expressed with the artesian-well water-supply. It is possible that more wells may be bored.

WASECA, MINN.—An artesian well is wanted.

ORTONVILLE, MINN.—Special city election by large majority decided to put in \$10,000 water-works.

GENEVA, N. Y.—Messrs. Chambers and Casey, contractors, of Rochester, N. Y., have been awarded the contract for building the pumping station (except the smoke stack) for the Geneva Water-Works Company. Price, \$6,500.

STROMSBURG, NEB.—The vote to bond this town for \$12,000 for a water-works system was unanimously carried, only one vote being cast in the negative.

JOHNSON CITY, TENN.—A contract has been entered into with C. M. Corpening, of N. C., to put in a water-works system in this town. It is expected that work will be begun within ninety days.

EAST JORDAN, MICH.—is discussing the water-works question; \$10,000 is the amount spoken of.

DAVID CITY, NEB.—The contract for the construction of a system of water-works for this place has been awarded to Messrs. Schroeder Bros.

MONTROSE, COL.—The Town Board considered the proposition made by Mr. Charles E. McConnell, of the Uncompahgre Valley, to supply the town of Montrose with pure water. The proposition was submitted last week to a vote of the taxpayers at a special election and accepted, there being but two negative votes.

WINFIELD, KAN.—The water system will be extended by several miles of water-mains.

PETERSBURG, ILL.—The City Council has awarded the contract for a system of water-works to D. Fisher, of this city. The cost of the works will be \$20,000. The work to be completed January 1 next.

MANKATO, MINN.—This city is extending her water-works plant.

GREENVILLE, O.—Our correspondent writes: "A proposition was made by Messrs. Lewis Comegys & Co., of New York, to construct and maintain water-works in this city, with seventy-five hydrants for fire purposes, for an annual rental of \$3,500. An ordinance was passed accepting the proposition, and an election was ordered for confirmation or rejection by electors. Before the time for said election had arrived, however, owing to the great public clamor against the improvement, Messrs. L. C. & Co. withdrew their proposition, and the matter was dropped." A special election will be held October 12.

NORFOLK, NEB.—Our correspondent writes: "The contracts for our water-works have been let and active operations will be commenced in a few days. A. L. Strang & Co., of Omaha, will build the system. It will be a direct pressure and stand-pipe system."

BONHAM, TEX.—advertisers for bids for a system of water-works. For further information address Mayor, Bonham, Tex.

WARE, MASS.—Plans are being prepared by Engineer Davis, of Northampton, for a new sewerage system.

CRETE, NEB.—The City Council is considering bids for water-works. It is expected that the contract will be made in favor of the Strang Co., of Omaha.

SALISBURY, MD.—J. B. Cloud & Co., N. Y., will build water-works costing \$25,000.

VINEYARD HAVEN, MASS.—Water-works will be built here.

CLYDE, KAN.—E. Sutphen, of this city, will build water-works at Greenleaf, Kan.

ELLENBURG, WASH. T.—is discussing the subject of water-works.

WASHINGTON, GEO.—A proposition to build water-works is wanted. The town has appropriated \$10,000.

GALLATIN, TENN.—A water-works system is being discussed.

GALLIPOLIS, O.—will vote on the question of a town water-works shortly.

TOLEDO, O.—A considerable amount of sewerage-work is to be done here.

TOLEDO, O.—A resolution has been introduced in the Council looking to the boring of an artesian well.

ATHOL, MASS.—Owing to legal complications, it is doubtful whether anything can be done at present in regard to the proposed sewerage scheme.

FORT FAIRFIELD, ME.—Our correspondent writes: "The prospect now is that we shall have water-works put in here next year, as the contract is all made."

WEATHERFORD, TEX.—Our correspondent writes: "We are corresponding with various water-works companies with a view of granting a franchise to some reliable company, but have not yet received any proposition from any company. Our city will grant a long-time franchise, and pay not less than \$1,000 per annum for fire protection, and more if the works are so constructed as not to necessitate the city to keep a fire-engine. Our population is about 4,000. Taxable property in 1886 was \$1,186,300 more this year."

HATFIELD, KAN., will have an artesian well.

A COMPANY is being formed to run an irrigating ditch from a point near Coolidge through northern part of Hamilton, Kearney and Finney Counties, Kansas.

OMAHA, NEB.—The Omaha Water-Works Company will lay water-mains and pipes in various parts of the city.

EAST TAWAS, MICH.—The Michigan Pipe Company, of Bay City, Mich., will put in the water-works at this city for \$28,000.

ENNIS, TEX.—Our correspondent writes: "Our city voted on the question of taxation for water purposes September 20, which resulted in 20 to 1 in favor of taxation. The work is in the hands of the Aldermen; the first attempt will be for an artesian well. The tax will be levied this year."

SALISBURY, MD.—Our correspondent writes: "Nothing has been done in regard to the water-works for this place."

ALBION, MICH.—Our correspondent writes: "Nothing doing at present; water-works system merely talked. No election held as yet. Will advise should the matter come to an election."

CAMDEN, N. J.—The question of the awarding of a contract for a filter has been postponed.

LA SALLE, ILL.—The estimated cost of the new water-works system at this place is \$121,000.

ONEIDA, N. Y.—Mr. Walter Randall, of Walton, and Mr. Jerome B. Tuckerman, of Eaton, will make surveys here for the purpose of constructing a system of sewerage, which will be introduced as soon as possible.

MILWAUKEE.—A 36-inch sewer will be built on the South side, from Reed Street to Starke's Slip. Water-mains will be laid on Cherry Street, from 20th to 24th Streets (4 blocks).

WILLIAMSBURG, IA.—Our correspondent writes: "Nothing has been done in regard to a water-supply except to bore a deep well, put in a pump, and erect a windmill to supply water at the corners of the square for watering teams and for drinking purposes. We are not able to do anything more at the present; probably will not before two years."

JACKSONVILLE, ILL.—The people of this city are said to be disappointed in the quality of the water-supply obtained through the artesian wells.

LAKE CITY, FLA.—At the last session of the City Council a charter was granted to Noyes S. Collins for the extension of the water-works system for this place.

MONTPELIER, VT.—At a special village meeting, September 26, a vote was passed to lay another water-main pipe from the reservoir in Berlin, at this place. The Treasurer was authorized to borrow a sum, not exceeding \$30,000, to meet the expenses.

COSHOCOTON, O., September 28, 1887.—Our correspondent writes: "We have let the contract for water-works under the franchise system to American Water-Supply Co., of McKeesport, Pa., providing it carries at the next special election, to be held next month."

CARSON CITY, MICH., has voted \$5,000 for water-works.

BESSEMER, ALA.—The water-works contract has been awarded to Scoville & Irwin, of Nashville, Tenn.

FOSTORIA, O.—Messrs. Ferris & Halliday, of Jersey City, N. J., have been awarded the contract for the new water-works at this place.

LANCASTER, PA.—See our "Proposal Columns" in regard to water-works for this place.

DULUTH, MINN.—The Gas and Water Co. contemplate building a high-service reservoir next season.

BENICIA, CAL., is not satisfied with its present water-supply.

McKEESPORT, PA.—Messrs. Snyder, Wilson & Co. have been awarded the contract for erecting a 5,000,000 gallon pumping engine.

EVANSTON, ILL.—The plan submitted by Mr. Grover for supplying North Evanston with water was adopted at the last meeting of the Trustees.

OAKLAND, CAL.—It is reported that the Contra Costa Water Co. will sell its property to the city for \$4,500,000.

MIDDLETOWN, N. Y.—The Anglo-Swiss Company are constructing a storage-reservoir for water, which will hold about 300,000 gallons.

SPRINGFIELD, ILL.—Colonel Hamer, representing a New York firm, is considering the proposition to purchase the water-works plant. If this is done, it is proposed that the city give the company a water-right and the privilege of improving Clear Lake by dredging and enlarging it, when a new system of water-works will be put in to supply the entire city. The city will be expected to take a specified number of hydrants at an agreed price. Pipes are to be laid throughout the city, and, after the completion of the new works, the city is to have the option of purchasing the plant.

MT. CARMEL, ILL.—The Mount Carmel Development Company has been incorporated; capital stock, \$3,000,000; to construct, maintain, and to operate a hydraulic canal from a point on Crawford Creek to Mount Carmel, for the purpose of supplying the city with water. Incorporators, Robert Bell, E. H. Green, S. Z. Landers, Amos Green, Theodore Green.

PHILADELPHIA, PA.—The Haverford Water Company and the Radnor Water Company have each increased their capital stock to \$100,000, and the Merion Water Company to \$500,000. The increases are said to be for the establishment of water-works in the suburbs.

LYNN, MASS.—At the last meeting of the Aldermen the report of the Committee on Water Supply, that the public board be instructed to purchase between 30 and 40 acres of land on the water-shed of Breed's Pond, was adopted. The land will cost about \$400 per acre.

FRANKLIN, NEB.—The new water-works for this place will be built by the Strang Company, of Omaha, Neb.

RISE LAKE, WIS.—A petition has been presented to the town council for a special election to vote on the question of bonding the city to raise funds for a water-works system.

THE Board of Directors of the Turlock Irrigation District of Stanislaus County have called a special election to be held on October 8, to consider the question of issuing bonds to the amount of \$500,000, for the purpose of constructing an irrigation system. The engineer in charge of the surveys estimates the cost at \$467,544.

NEWPORT, R. I.—A special session of the City Council has been held to take action on a petition received from the summer residents, representing over \$6,500,000 worth of taxable property, for the construction of a sewerage system.

DUBUQUE, IOWA.—A special election took place on September 30, for the purpose of determining whether the people wanted a sewerage system or not. All previous votes for sewer construction have been rejected.

PANAMA.—It is reported that a company is endeavoring to obtain a charter to supply this city with water, but that the Government is unfavorably disposed to the project. The president of the company is M. Luis de Bigot.

DECATUR, ALA.—Howland & Ellis, of Boston, have the contract for the new water-works here.

GAINESVILLE, TEX.—The Gainesville Water Co. has increased its capital and will extend its service.

FAVRETTVILLE, IND.—A movement is on foot to secure the establishment of a water-works system here. Address F. R. Rose.

GAS AND ELECTRIC-LIGHTING.

ORANGE, MASS.—At a special meeting of the Town Council, held last week, it was decided to accept the proposition of the Electric Light Company for lighting the streets. The company has a capital stock of \$10,000 and will be known as the Orange Electric Light Company. The plant will be in and ready for use about December 1, 1887.

JANESVILLE, WIS., is to have an electric fire alarm system.

MADISON, WIS.—The West Superior Manufacturing Company has been incorporated; also the North La Crosse Gas-Light Co., each having a capital stock of \$50,000.

OAKLAND, ME., is to have electric-lights. A number of lights are guaranteed.

MEMPHIS, TENN.—The Equitable Gas-Light Co., recently granted the right of way through the city, has purchased twenty-five acres of land in the southern portion of the city, where they will erect their works. The price paid was \$30,000. Work will be commenced within the next thirty days.

PHILADELPHIA.—Arrangements have been completed for the purchase of the Northern Liberties Gas-Works of this city by a private corporation, the members of which are at present unknown.

MOBILE, ALA.—The Progressive Electric-Light Co. will construct a plant here.

ST. ALBANS, VT., wants electric-light.

DAYTONA, FLA., wants an electric-light plant.

OMAHA, NEB.—The subject of lighting the streets by gas or electricity has not yet been decided.

DES MOINES, IOWA.—The city's contract with the Capital City Gas Co. expires January 1, 1888, and several electric-light companies are after the business of illuminating the city. The Capital City Gas Co. proposes to light the business portion of the city with 100 arc-lights of 2,000 candle-power each for \$12 per light per month in accordance with the provisions respecting gas-light ordinances. The Thomson-Houston Company makes three separate propositions:

One hundred or more lights for five years' contract, from twilight to daylight, per light per month, every night, \$15.

Moon schedule, every night, \$11.75.

From twilight to midnight, \$9.90.

Ten years' contract, all night, \$14 per lamp per month.

Moon schedule, \$10.75. From twilight to midnight, \$9.

Fifteen years' contract, lamp to burn all night, \$13 per lamp per month.

Moon schedule (which means the lamps are not to be lighted on moonlight nights), \$10. Twilight to midnight, \$8.50.

The bids are under consideration.

YORK, NEB.—A company has been organized to put in electric-lights, the City Council having granted a franchise.

CANISTOTA, N. Y.—The Canistota Electric-Light Co. will erect a plant.

KALAMAZOO, MICH.—More electric-lights are wanted.

HAYWARDS, CAL.—There is a proposition on foot to have the town lighted by electricity.

SMELSVILLE, ILL.—The Shelbyville Water Company has added a large dynamo to its works, and will hereafter furnish the city with electric-lights.

BERKELEY, CAL.—Incorporated are the Berkeley Electric-Light Co., capital stock, \$30,000; directors are: R. P. Thomas, J. B. Henley, Daniel Dowling, Robert W. Anderson, and R. C. Dorman; the East Berkeley Electric-Light Company; the trustees for the first year are: J. L. Barker, A. Bartlett, George Schmidt, Louis Gottshall, M. H. Strelinger, C. K. Clark, A. F. Gunn, W. P. Moore, and W. C. Jones; the capital stock is \$30,000.

WEBSTER CITY, IOWA, is excited over the natural gas question. At a recent meeting \$3,000 was raised for the purpose of opening a well.

READING, PA.—The steam-heating company is at work laying its plant. A quantity of material will be wanted.

ELYRIA, O., wants a gas-lighting system.

BROOKFIELD, N. Y.—The American Electric Light Co.'s bid is \$60 per lamp annually for a five years' franchise. The trustees are not in favor of giving a franchise for five years, but offer to give a franchise for one year at a stated price and the privilege of extending it for four years more, provided the company receiving the award agree to furnish the lights as cheap as any other company.

COHOES, N. Y.—A company, to be known as the Cohoes Electric-Light Company, has contracted to illuminate this village. Five large dynamos will be placed in position in a few days, as will also two immense 100-horse-power engines. The dynamos will be operated by water power, but in case of emergency steam power will be used. The contract for the lighting of 10 electric-lamps was given to the gas-light company about three months ago, but they did not fulfill the agreement. The new company is composed of members of the gas company, and it is now thought that the city will be lighted next week.

CARROLL, IOWA, will have electric-lights.

ROCHESTER, MINN.—Work will shortly be commenced on a new gas works. A quantity of pipe is needed.

CAMDEN, N. J.—About \$60,000 worth of new gas pipe will be laid this year.

CHARLESTON, S. C.—The Charleston Electric-Light and Power Co. are making preparations to introduce the incandescent light in this city. The plant has already been purchased.

CEDAR RAPIDS, IOWA.—The Cedar Rapids Electric-Light Co. have increased their capital stock by \$75,000 and will increase their plant.

BROWNSVILLE, PA.—The American Gas Improvement Co., of Pittsburgh, will erect gas-works here.

AMERICUS, GEO.—Howland & Ellis, of Boston, Mass. have the contract for the new gas works at this place.

GADSDEN, ALA.—The Queen City Electric-Light Co. is contemplating increasing its plant.

BESSEMER, ALA.—An electric-light and power company has been organized with a capital of \$30,000. The company will erect a 150-foot tower, and are negotiating for suitable engine and boiler. Address, for further particulars, Mr. H. H. Judson, Secretary.

JAMAICA, L. I.—Bids are wanted for lighting the streets of the village. Until October 5. Address John Distler, Jamaica, or Jerome Covert, 74 South Street, New York.

BRIDGES.

CHICAGO, ILL.—The plans for the new bridge to cost \$50,000, to be erected at 106th Street, are completed, and bids are asked for.

LOS ANGELES, CAL.—A motion is on foot to build a dry dock at San Pedro. A number of San Francisco capitalists are interested in this scheme. The proposed dock is to be 1,500 feet long and the estimated cost \$300,000.

KINGSTON, N. Y.—A meeting of the joint committee from the city of Kingston and the town of Austin was held recently to consider the question of the new bridge to be built across Esopus Creek in Kingston. The following were the bids: From Wallace Brothers, \$8,136; King Bridge Company, Plan No. 2, \$5,236; King Bridge Company, Plan No. 1, \$4,500; Morse Bridge Company, \$4,975; Dean & Westbrook, \$4,600; Berlin Bridge Company, \$4,450. The contract was awarded to Dean & Westbrook for \$4,600. The committee will execute the contract at once.

TUSCALOOSA, ALA.—The contract for building a bridge for the Tuscaloosa and Northern Railroad Co., at this place, has been awarded to Messrs. Riley & Goode, of Atlanta, Geo.

LOUISVILLE, KY.—The new Beargrass Bridge will be rejected by the City Engineer. If this action is approved by the Common Council, the bridge will be torn down and re-erected.

SAN FRANCISCO, CAL.—See our proposal column in regard to a large pier to be built here.

SCITUATE, MASS.—The citizens of this place have raised a petition asking that the Old Colony Railroad Co. be compelled to build a draw-bridge over the North River. The present railroad bridge contains no draw. The company seem unwilling to construct a new bridge and offer to raise the present bridge.

ELIZABETH, PA.—\$30,000 has been subscribed for building a bridge at this place. The company has been organized under the title of the Elizabeth Bridge Co. W. M. Ekin is the Solicitor. At the next meeting officers and directors will be elected and arrangements made for procuring a charter.

FREMONT, SCHUYLKILL CO., PA.—wants bids for an iron bridge until October 10. John Healy is Commissioner.

FOND DU LAC, WIS.—Address the City Engineer for information concerning the erection of two bridges.

FREMONT, O.—A new iron bridge will be built by the L. E. & Western Railroad.

GOLIAD, TEX.—Address the City Clerk in regard to proposals for an iron bridge to be built across the San Antonio River. Bids received until October 20.

SANTA ROSA, CAL.—Address the Mayor for information concerning two new bridges to be constructed here.

WOONSOCKET, R. I.—At a special town meeting called to consider the request of fifteen taxpayers for the rescinding of the vote appropriating \$6,000 to build a bridge across Blackstone River, at Fairmount, it was decided not to rescind the vote and the bridge will accordingly be built. Address Joseph L. Brown for information.

BOSTON, MASS.—An effort will be made at the next meeting of the Common Council to pass an order authorizing the Treasurer to borrow \$250,000 for the expense of building the new bridge at Cambridge.

BUXTON STATION, MD.—It is proposed to build an iron bridge to span the railway near this place, with an average thickness of abutments of five feet. The estimated cost will be about \$8,000, the expense to be divided among the owners of the neighboring property, the county and the railway company.

ELIZABETH, PA.—The County Commissioners will build a \$50,000 bridge.

JEFFERSONVILLE, IND.—The Louisville and Jeffersonville Bridge Company will build a bridge over the Ohio River at this place.

WHEELING, W. VA.—A Union Railroad Bridge over the Ohio River is contemplated. A joint meeting, composed of the Ohio County Commissioners, Wheeling City Commissioners, and Chamber of Commerce, appointed a committee of six to treat with John A. Lynch and R. H. Cochran, of Ohio, with a view towards raising a public subscription of \$50,000 for the bridge. The United States Government has approved the plans, and given permission to erect the bridge.

ROANOKE, VA.—The Shenandoah Valley Railroad Co. contemplate renewing several small wooden bridges with iron.

FORT WAYNE, IND.—The contract for the abutments of the new bridge over the St. Mary's River at Spy Run has been awarded to Henry C. Paul. No bids for the superstructure will be received.

CHATTANOOGA, TENN.—It is expected that the contract with the city for building the bridge across the river will be signed at the next regular meeting of the Council.

TOLEDO, O.—The City Council has passed a resolution directing the City Engineer to prepare plans for an iron bridge over the Lake Shore Railroad at Sumner Street.

LOCKPORT, ILL.—See our Proposal Columns in regard to an iron bridge at this place.

CHICAGO, ILL.—An ordinance has passed the City Council providing for the erection of a double bridge at Madison Street.

BARRE, MASS.—At a town meeting held Saturday, it was voted to place an iron bridge across Ware River, near the Barre Station, on the Central Massachusetts.

SAN FRANCISCO, CAL.—The Chief Engineer of the San Francisco Bridge Co. has been instructed to prepare plans and specifications for a shed to be erected over Greenwich Street wharf.

DETROIT, MICH.—A special committee of the Town Council is considering plans and bids for the Belle Isle Bridge.

NORTHAMPTON, MASS.—E. C. Davis has been awarded the contract for building a bridge at Easthampton.

STREET WORK AND PAVING.

MILWAUKEE, WIS.—The contract for furnishing cedar blocks for paving Virginia Street has been awarded to C. A. Beck at 64 cents per square yard. Bids for laying the blocks were submitted by James Hoyer, at \$1.37 1/4; C. Murphy, at \$1.13, and John O'Connell, at \$1.27; but the contract was not awarded.

WILMINGTON, DEL.—Paving will be done on Front Street and Maryland Avenue. Address Joseph L. Carpenter, Jr., President of Directors of the Street and Sewer Department.

NEW YORK CITY.—The Dock Commissioners, September 22, sent to the Sinking Fund Commissioners plans prepared by Engineer Greene for an exterior street, 150 feet wide, under the bluff on the East River, from Sixty-fourth Street to Eighty-sixth Street; \$65,000 will be required.

STILLWATER, MINN.—City Council, September 13, appropriated \$60,000 to improvements. One of these is the paving of Main Street with cedar blocks.

NEWARK, N. J.—Street and sewer work is ordered done in Bloomfield Avenue, Norfolk Street, Oriental Street, Bergen and Magnolia Streets. Address John Hunkele, Street Commissioner.

ALBANY, N. Y.—Bids for various street-work have been opened, as below, by the Board of Contract and Apportionment. The following bids were received for paving with cobblestone West Street, from Perry to Quail:

	Paving per yd.	Curb per lin. ft.	Old curb relaid.	Crosswalk sq. yd.
Jacob Holler	\$1.05	\$0.65	\$0.35	\$0.38
A. N. Brady	1.00	.50	.16	.40

The contract was awarded to A. N. Brady. The following bids were also received for laying a 12-inch vitrified pipe drain in Yates Street, from Lexington Avenue to Robin Street:

	Vit. pipe per foot.	Y branches.	Rec'g basins.	Man-holes.
Jacob Holler	\$0.73	\$2.55	\$62.00	\$75.00
John Doyle	.90	3.00	61.10	60.00

The contract was awarded to Jacob Holler.

The following apportionments for the improvements were approved: Central Avenue pavement, between Lark and Knox, \$9,938; Columbia Street pavement, between Chapel and Eagle, \$3,974.30; Beaver Street drain, from Green to Broadway, \$687.57; Beaver Street drain, from South Pearl to Green, \$765.00; First Street sidewalk, from Lark to Knox, \$45.58; Colonic Street pavement, \$5,832.57.

CEDAR RAPIDS, IOWA.—Paving is ordered on First Avenue and other streets. Address John Gates, Acting Mayor.

SAVANNAH, GEO.—A number of streets are to be paved here.

LAKE, ILL.—\$90,000 has been voted for municipal improvements.

SARATOGA, N. Y.—The Water Commissioners will ask bids for laying a 4-inch pipe through several streets. Address Samuel F. Corey, Clerk.

JERSEY CITY, N. J.—Address Martin Finck, Clerk Board of Public Works, in regard to the improvement of various streets.

SAN JOSE, CAL.—The Common Council has adopted the report of the Street Committee recommending the improvement of various streets.

OAKLAND, CAL.—It is expected the City Council will have a special election, to vote upon the proposition to emit \$1,000,000 in bonds, the proceeds to be used for public works.

SANTA ROSA, CAL.—Among the improvements contemplated by the City Council are two new sewers, two new bridges, the grading of several streets, and the erection of a new hose-house.

NEW LOTS, L. I.—The Local Improvement Co. have decided to pave the following streets with Belgian pavement as follows: Glenwood Street, from Jamaica Avenue to the Eastern Parkway, at a cost of \$40,000; Van Siclen Avenue, from Jamaica Avenue to the Eastern Parkway, at a cost of \$40,000; and Arlington Avenue, from Fulton Street to Jamaica, at a cost of \$55,000.

ANTIGO, WIS.—\$8,000 worth of bonds have been issued to pay for town improvements.

HYDE PARK, ILL.—\$10,000 has been voted for granite block roadbed.

HARTFORD, CONN.—At the last meeting of City Council a petition was presented asking for an extra appropriation for the street department. The petition was granted and \$20,000 was appropriated for this purpose.

LOWELL, MASS.—The City Council has appropriated \$6,000 for street work.

CAMDEN, N. J.—An ordinance appropriating \$3,000 for new sewers was passed at the last session of the City Council.

For street-work in Allegheny, Pa., address James Brown, Comptroller, until October 6.

RAILROADS, CANALS, ETC.

EAST ST. LOUIS, MO.—Large railroad-frog works are to be erected here.

SEATTLE, W. T.—The Seattle Cable Road and Water Company will construct a cable road in this city within six months.

JACKSONVILLE, FLA.—A new street railway company, to be known as the Jacksonville Suburban and Real Estate and Railroad Company, has been formed in this city, with the following officers: President, Henry A. L'Engle; Secretary, C. F. Adams; Treasurer, W. A. Bisbee.

CHICAGO.—A harbor, with canal, piers, and storehouses, will be developed in East Chicago by the Calumet Canal and Improvement Company, the Chicago and Calumet Terminal Railroad Company, and the State Line and Indiana City Railway Company. Much dredging is to be done.

TOPEKA, KAN.—The City Engineer has prepared plans for a viaduct for the railways at Sixth Street.

TALLAHASSEE, FLA.—The preliminary surveys on the Thomasville, Tallahassee, and Monticello Railroad have been completed. H. S. Haines, Chief Engineer and General Manager of the Plant Investment Company, advertises for bids for the construction of that portion of the railroad from Thomasville, Geo., to the Florida State line.

MARION, IND.—The construction of the first fifty miles of the road from this place is to be begun at once. Address J. H. Cahoe for information.

WINNIPEG, MANITOBA.—The contract for the North-west Central Line has been made with Mr. J. C. Sproule, of this place. The contract calls for the completion of the line by January 1, 1888.

MILWAUKEE.—The West-Side Street Railway Co. will extend their tracks on Eleventh Street to Clybourne Street, and on Clybourne Street to Washington Avenue, a distance of about 550 feet. Washington Becker is the owner and manager.

SANTA BARBARA, CAL.—The Board of Supervisors, September 12, granted a franchise to H. L. Williams to build an electric railroad from Santa Barbara, through Montecito Valley, distance about 10 miles.

SACRAMENTO, CAL.—The Board of Trustees, September 12, granted franchises to G. W. and R. S. Carey to construct a street railway.

WOODLAND, CAL.—The City Trustees of Woodland have granted a franchise to Coward & Lawson to build a street car line. Work is to be commenced within 90 days.

SANTA ROSA, CAL.—The Santa Rosa and Carquinez Railroad Company has received right of way through the city, and work will go on at once.

SEATTLE, WASH. T.—The contract for building the second 40 miles of the Seattle, Lake Shore and Eastern Railway will be let within the next 30 days, and within the next 12 months 300 miles, extending into Eastern Washington, will be constructed.

NORFOLK, NRB.—is to have a street railroad connecting this town with Norfolk Junction.

MINNEAPOLIS, MINN.—The Minneapolis and Pacific Railroad is to build a new elevator near Shingle Creek. The cost is estimated at \$118,000.

ST. JOSEPH, MO.—The contract for building the Wyatt Park Cable Road has been awarded to J. T. Lerner, of Plainfield. The bid was for \$450,000 for 4 1/2 miles of road, and included the erection of powerhouse. Work will be begun about the middle of October, and it is expected that the road will be completed by January, 1888.

WINNIPEG, MANITOBA.—The contract to build the first 40 miles of the Port Arthur, Duluth, and Western Railroad has been awarded to Messrs. Grant & Ross. The 40 miles are to be finished by August 1, 1888.

KNOXVILLE, TENN.—The East Tennessee, Virginia, and Georgia Railway Company, will construct a road running from this city to Powell Valley. The cost of the road will be \$15,000,000. Address C. H. Hudson, General Superintendent.

SCHENECTADY, N. Y.—A new railroad is to be built by the Schenectady and Ogdensburg Railroad Co. For information address Messrs. Nye & Wiltzie, of New York.

MANITOWOC, WIS.—has asked for a franchise for a street railway.

CHATTANOOGA, TENN.—A company has been formed for the purpose of starting a horse-car road on Mission Ridge, from the tunnel to Rossville Gap, a distance of about six miles. A charter has been applied for and work will be begun at once.

SAN FRANCISCO, CAL.—A franchise has been granted to operate a street railway from California Street to Golden Gate Park, and the contracts (two in number) for its construction have been awarded.

RAILROAD.—Address McDonald, Shea & Co., Birmingham, Ala., in regard to work to be let on the Clinton and Oliver Springs Road.

OAKLAND, CAL.—A petition has been sent to the Common Council for a street railroad. Address R. Chabot for information.

SALT LAKE CITY, UTAH.—The construction of the Salt Lake City and Los Angeles Railway will be begun shortly. Address Caleb W. West for information.

RAILROADS.—The contracts for building the Pittston, Pa., and Fairview branch of the Lehigh Valley Railroad have been awarded to Smith & Ripley, of New York; Charles McFadden, of Philadelphia; John McGovern, of Towanda, and Broadhead & Hickey, of Scranton.

ST. PAUL, MINN.—The Cherokee & Dakota Railroad Company, of Dubuque, Iowa, is organized for building a railroad from Cherokee, Iowa, into Nebraska, Minnesota and Dakota. The capital stock is \$4,000,000, and the incorporators are: Edward L. Jeffery and John C. Willing of Chicago, and William J. Knight, M. Gilles, F. W. Quimby, J. Jacobs and William R. Palmer, of Dubuque, Iowa.

MONTREAL, CAN.—The contract for the Massena Springs and Fort Covington Railroad, New York State, has been awarded to Rogers & Taylor, of Montreal. This line will connect Montreal and Champlain Junction with the Rome, Watertown & Ogdensburg and other American lines, and will be constructed at once.

LINCOLN, NEB.—The Pacific Railway of Kansas has filed articles with the Secretary of State consolidating with the Pacific Railway of Nebraska. The road runs from Warwick, Kan., to Hastings, Neb., and its capital stock has been increased to \$2,600,000.

MADISON, WIS.—Incorporated is the Milwaukee Electric-Railway Company; capital stock, \$50,000, incorporators: R. Nunnemacher, Edwin A. Bartlett, John A. George, John M. Stowell, C. F. Freeman, Francis Boyd, C. E. Lewis, Cornelius I. Harwig, Henry C. Payne, Adolph Tallner, and Benjamin M. Weit. The object is the construction and operation of an electric stock railway in Milwaukee.

WINONA, KAN.—The Winona and South-western directors have closed a contract to build that road with a syndicate of Minneapolis capitalists, headed by General Nettleton. The road is to be in operation to Omaha by January 1, 1890.

NEW BRUNSWICK, N. J.—Surveyors have been at work upon a new railroad which will be built from Bound Brook to South Amboy, with stations in this city, Milton, Sayreville, and South River. The road will be a feeder for the Philadelphia and Reading Railroad, and will take the latter to tidewater in Kantan Bay. The men interested in the road are known to be H. G. Little, Congressman Kean, Miles Ross, Christopher Meyer.

PADUCAH, CHICASAW, and Birmingham Railroad has been incorporated. Principal office, Birmingham, Ala.; incorporators, James Jackson, J. B. Moore, and others.

BIRMINGHAM, ALA.—Organized is the Birmingham, Mobile, and Navy Cove Railroad Company to build a road from Birmingham to Mobile; estimated cost, \$2,500,000.

MISCELLANEOUS.

MANKATO, MINN. will issue \$15,000 bonds for new parks.

NEW YORK.—Congress will be petitioned for an appropriation of \$30,000 for the purpose of deepening the channel between Wave Crest and Jamaica Bay.

DAVENPORT, IOWA.—Messrs. Walsh & Edwards have been awarded the contract for the stone-work, and Messrs. Garstang & Valentine the contract for the brick-work for the new business house to be erected by Messrs. A. J. Smith & Son.

BOSTON, MASS.—A license has been granted to the Lewis Wharf Co. to build a sea wall and pile-wharf in Boston Harbor.

SAN FRANCISCO, CAL.—A 1,000-ton steel steamer will be built at the Union Iron-Works.

PHILADELPHIA, PA.—The Pennsylvania Iron-Works have been awarded the contract to build a steel vessel, 1,000 tons, for coast services, for the Pacific Steamship Company. Cost will be between \$175,000 and \$200,000.

AUGUSTA, GEO.—The sum of \$5,000 is to be expended for an elevator and gas and water pipe for the new Masonic Temple. Address the architect, Mr. Woodruff, Macon, Geo.

BRADFORD, PA.—The Edgar Thompson Steel Works will build a furnace costing \$300,000.

BIDS OPENED.

YOUNGSTOWN, O.—Bids were opened September 22 at 12 o'clock m. for constructing a brick sewer in Wick Street, about 1,925 feet long and 30 inches inside diameter, 6 catch-basins and 5 manholes. Other inlets supplied by cross-sewers.

King & McClure, 1,925 feet at \$2.25, total \$4,331.25; 6 catch-basins, \$180; 5 manholes, \$130; grand total, \$4,641.25.

John Megown, \$2.30, \$4,427.50, \$105, \$170; total, \$4,702.50.

Con O'Donnell, \$2.33, \$4,485.25, \$270, \$120; total, \$4,875.25.

Davis & Caldwell, \$2.95, \$5,678.75, \$150, \$200; total, \$6,028.75.

WILMINGTON, DEL.—The following contracts have been awarded by the Sewer Department: Davis & Bro. were awarded the contract for laying Belgian block on Front Street from Jackson to Justison, and on Maryland Avenue from the intersection of Front Street to Chestnut at 25 cents per square yard. John Dolan was awarded the contract for grading on Front Street from Jackson to Justison at 15 cents per yard, and Martin Keogh the grading of Maryland Avenue from the intersection of Front Street to Chestnut at 14 1/2 cents per yard.

ST. PAUL.—The contract of A. O. Noepel, Des Moines, Iowa, for steam-heating the new Court-House and City Hall, failed to be confirmed by the joint meeting of the Common Council and County Commissioners. In doubt what action will be taken.

MILWAUKEE.—Bids for furnishing the Wauwatosa Water-Works with a hose-cart, hose, etc., opened September 26, 1887:

For building hose-house, G. F. Steuwe, \$1,750; Henry Mueller, \$1,744.

For furnishing 2,000 feet 3/4 jacket-hose, and 4 play-pipes: The Gutta-Percha and Rubber Co., Chicago, \$1,475; A. H. Gardner & Co., Milwaukee, \$1,560; A. E. Foote & Co., Milwaukee, \$1,600; H. J. Delaney & Co., Milwaukee, \$1,600. A. E. Foote & Co. will furnish 1,000 feet at \$800, and H. J. Delaney & Co. the other 1,000 at same price, to whom the contracts were let.

To extend the water-pipe to the County Almshouse at Wauwatosa, September 26, 1887: Eben Badger, \$2,095.

Furnishing cedar blocks for paving Virginia Street, C. A. Beck, 64c. per square yard.

Contractor J. W. Murphy was the lowest on the new sewer for the Ninth Ward school. His bid of 72 cents per foot secured him the contract. The highest bid received was \$1 per foot.

BOSTON, MASS.—The Boston Water Board on Tuesday received proposals for building an iron roof for an engine-house at the Chestnut Hill Pumping-Station. The terms of the bids required among other things a certified check for \$100. Messrs. Cotrode & Saylor offered to do the work for \$9,861, and the Boston Bridge-Works \$6,845. The latter did not send a certified check as required, and the contract was awarded to Cotrode & Saylor.

ANNISTON, ALA.—Mr. Badders has been awarded the contract for an \$8,000 public school.

ALLENTOWN, PA.—Mr. Thomas W. Snyder, of this city, has been awarded the contract for the new silk mill at Weatherly, costing \$24,000.

DAVENPORT, IOWA.—The Davenport Steam-Heating Company have been awarded the contract for the heating-apparatus for the Masonic Temple building at a cost of \$5,000.

MILWAUKEE, WIS.—The Board of Public Works opened bids for building new school-houses in the Sixth and Fifteenth Wards and for doing the plumbing and steam-heating in both. There were thirteen bidders for the Sixth Ward building as follows: H. Schlenstead, \$42,400; A. H. Vogel, \$42,208; F. G. Horning, \$43,800; H. Schmidt, \$43,533; H. P. Muilen, \$41,700; Charles Kraatz, \$40,843; Henry Hoffmann, \$43,148; Oscar Knie, \$40,982; August Wendt, \$43,300; H. Berg, \$45,600; Henry Ferge, \$41,983; Joseph Leneschek, \$43,100; M. P. Klocksin, \$41,100. W. E. Goodman bid \$1,246 for doing the plumbing; E. T. Doyn, \$1,188, and O. H. Murphy, \$1,390. For the steam-heating apparatus, C. A. Barker wanted \$5,248; M. Coogan, \$4,700, and H. Mooers & Co., \$4,975.

For the Fifteenth Ward building, Charles Kraatz bid \$19,943, and A. H. Vogel, \$21,608. W. E. Goodman wanted \$720 for the plumbing; P. H. Murphy, \$800, and R. J. Finn, \$798. Charles A. Barker wanted \$2,895 for the steam-heating apparatus; H. Mooers & Co., \$2,970, and M. Coogan, \$2,800.

In both cases the total of the bids exceeds the appropriation and they were laid over for consideration.

ALBANY, N. Y.—The following bids for building slope-wall at Corning, N. Y., were received by the Superintendent of Public Works, September 27, 1887: Fitzpatrick & Noonan, Havana, \$8.90; McGreevy & Murray, Elmira, \$7.88; Griffin & Gorton, Corning, \$9.25. The above are the prices per lineal foot. Awarded to McGreevy & Murray.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1887, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 16. }
NUMBER 19. } PUBLISHED EVERY SATURDAY.

NEW YORK, OCTOBER 8, 1887.

LONDON, OCTOBER 22, 1887.

SINGLE COPIES, TEN CENTS.
Subscription, \$4.00 per year in advance, post paid. } IN AMERICA
SINGLE COPIES, SIXPENCE.
Subscription, 20s. per annum in advance, post paid. } IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD,
conducted by HENRY C. MEYER, is published every Saturday at 82 & 84 Fulton Street, New York. Its opinions upon all technical subjects are either prepared or revised by specialists.

TERMS, \$4 PER YEAR, IN ADVANCE.
Postage Paid.

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.

TERMS, 20s. PER YEAR, IN ADVANCE. Postage Paid.
SINGLE COPIES, SIXPENCE.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York), and crossed ——— & Co.

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzig, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, \$5; China, Japan, Sandwich Islands, Mexico and Cuba, \$5; South America, \$5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us promptly of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

ANNOUNCEMENT.

WE have decided to change the name of this journal to the title given in this issue. It is not intended to change the character of the paper. Our object is simply to convey by the first part of the name adopted the scope of the matter it regularly gives its readers.

THE UNITED STATES LIFE-SAVING SERVICE.

FROM time to time throughout the year the daily press gives an account of a shipwreck, and in most cases this account includes a more or less detailed history of the efforts of the crew of some life-saving station to rescue from the angry sea the imperilled passengers and sailors. These stories are read and soon forgotten except by the few who took part in the struggle, or possibly by some writer of romance who finds in them the best possible material for his work. But when these brief histories are brought together, as has been done for the year ending June 30, 1886, in the Annual Report of the Life-Saving Service Bureau of the Treasury Department, it forms a volume of over 500 pages, which gives one a realizing sense of the importance and extent of this branch of Government work.

The United States Life-Saving Service includes 211 stations, of which 165 are on the Atlantic coast, 38 on the Lakes, 7 on the Pacific coast, and one at the Falls of the Ohio, at Louisville, Ky. These stations had to do with 322 disasters to documented vessels during the year, involving property valued at \$6,502,135, and 2,726 lives. Of the lives 2,699 were saved and 27 lost; of the property \$5,073,078 was saved and \$1,429,057 lost.

The total expenditure for the service during the year, including salaries of officers and clerks in the central office, was a little over \$870,000. It is a large sum, but one which is extremely well invested in view of the results obtained, and we believe there is no bureau which is more carefully and economically managed or which is more deserving of public approval and support.

RAILWAY-STATION ARCHITECTURE.

SOME of the railroads in this country, notably the Boston and Albany and the Northern Pacific, have shown a praiseworthy spirit in setting the example of employing skillful architects to design the small as well as large railway-stations.

They have thus built buildings most pleasing in appearance and with much added comfort and convenience above the desolate-looking structures which add not a little to the *ennui* of travel.

The late H. H. Richardson may be said to have developed the type of American railway-station adopted by our leading architects.

By the use of the simplest constructional means, with no "constructed ornamentation," he produced buildings strikingly original and artistic in form with no sacrifice of practical considerations and with many features which, while adding much to the architectural effect of the whole, have rendered the structures more serviceable for their purpose.

The managers of the roads who have employed first-rate architectural talent in these con-

structions will have not only the satisfaction of doing the "civilized" thing, but will find, as they probably now appreciate, that there is commercial value in beauty.

SANITARY ENGINEERING AND ITS RESULTS AS ILLUSTRATED IN THE CITY OF DUBLIN.

IN the year 1879 active measures for the improvement of the sanitary condition of Dublin were commenced by the corporation. Over \$150,000 were expended in sewer construction; 4,350 water-closets have been put in place and connected with the sewers; two large, greatly overcrowded and unhealthy areas have been cleared, at a cost of about \$280,000; over \$550,000 have been expended in construction and paving of streets; an abattoir has been established, at a cost of about \$75,000; over \$50,000 has been expended in the construction of public baths and wash-houses, and over \$110,000 in domestic scavenging. Much has been done towards improving the condition of the tenement-house population, and 7,000 persons now inhabit the houses of the Dublin Artisans' Dwellings Company. In April, 1881, the population of the city proper was 249,602, numbering 54,275 families, and inhabiting 24,211 houses. At present the population of the city proper is estimated at 252,239, and of the whole registration district at 353,082.

It is not yet time to perceive the full effect of the sanitary work which has been done, but some results are fairly stated in the last report of the Medical Officer of Health, Sir A. C. Cameron, for the year 1886, and to these we would invite the attention of our municipal authorities.

As Dr. Cameron remarks, the fact that there is a relatively greater number of very poor persons in Dublin than in most other large cities must be remembered in considering the death-rates. In English towns 17 per cent. of the deaths occur in workhouses and charitable institutions, while in Dublin the proportion of deaths in such institutions is 30 per cent. The death-rate for all ages was, in 1879, 35.7 per 1,000; in 1880, 35.9; and the yearly average death-rate for the ten years, 1876-85, was 29.5. In 1886 the death-rate was 26.9. One of the best tests of the results of municipal sanitary work is, as our readers know, the effect which it produces on infant mortality. In 1879 the death-rate of children under five years of age was 109.6 per 1,000, in 1880 it was 133.6, and the average for the ten years, 1876-85, was 90.2. In 1886 it was 30.8.

While the figures are by no means conclusive proof of increased healthfulness, since the death-rates in 1886 were low almost everywhere, they do give very good evidence of improvement when taken in connection with certain details, such as the great diminution in the annual number of deaths from typhus.

The work of improvement is going on steadily—79 houses were distenanted and closed during the year 1886 as being unfit for human habitation, 48,327 inspections of tenement-houses were made by the seventeen inspectors engaged on that work, and the estimated expenditure by the Public Health Committee is a little over \$100,000.

It is expensive work to put an old, crowded town, with polluted soil, unpaved streets, and old-fashioned, leaky sewers, into good condition, but it pays after all. We congratulate the Dublin

RESIDENCE OF S. P. STAMBACH, ESQ., HAVERFORD COLLEGE, PA.—CHARLES BALDERSTON, ARCHITECT.

THE SANITARY ENGINEER AND CONSTRUCTION RECORD ILLUSTRATED SERIES.

AN OLD COLONIAL HOUSE AT JAMAICA PLAIN, MASS.

authorities on the excellent showing that Dr. Cameron makes in his last report, and hope that five years hence they will find that the improvement in the health of the city is so distinct that there can be no doubt of the profit from their expenditure and labors.

THE "AMERICA'S" CUP AND AMERICAN VERSUS ENGLISH YACHT MODELS.

THE result of the yacht races on the 27th and 30th of last month and the general interest they excited well justify a summary of the races for this famous cup.

In 1851 some members of the New York Yacht Club sent the schooner yacht "America" to the other side as an addition to our display at the Universal Exposition of that year—and for a cup. The only race secured was at Cowes, August 22, against the entire fleet of the Royal Yacht Club. It is related that when the Queen, on being told that the "America" had beaten, inquired what yacht was next, was answered: "May it please Your Majesty, there is no next."

In 1857 the cup was given to the New York Yacht Club as a challenge cup, remaining in their undisturbed custody till 1870, when James Ashbury challenged for it with the "Cambria." Seventeen American yachts entered to defend the cup in a race sailed August 8 of that year, nine of them beating the "Cambria."

In 1871 Mr. Ashbury returned with the "Livonia" to sail the best four out of seven races with a single yacht to be selected by the New York Yacht Club the morning of the race. In October three races were sailed between the "Livonia" and "Columbia," the "Columbia" breaking its steering-gear in the third race and losing it. Two more races were sailed with the "Sappho," both in favor of the American yacht.

In 1876 the Canadians sent the "Countess of Dufferin" to be beaten August 11 and 12 by the "Madeleine," and in 1881 they returned with the "Atalanta," which was beaten November 9 and 10 by the "Mischief."

There were no further contests until 1885, when Sir Richard Sutton sent over the "Genesta." At this time many Americans were in doubt as to the relative advantages of the centre-board and deep-keel or cutter types, and some thought that a cutter should be built to defend the cup. Instead, the "Puritan" and "Priscilla" were built, both centre-board sloops, of which the "Puritan," designed by Burgess, was selected, and beat the "Genesta" September 14th and 16th.

Lieutenant Henn challenged with the "Galeata" for the races of 1886; again two centre-board sloops were built, the "Mayflower" and "Atlantic," the first by Burgess and the other by Ellsworth and a syndicate. Of course, the one man's sloop was the best and it beat the "Genesta" on September 7 and 11, to the pride of all Americans, which was mingled with a feeling of sorrow for Lieutenant Henn's defeat.

This year, as all know, the "Thistle," built by a Scotch syndicate, was badly beaten by the "Volunteer," another of Burgess' peerless boats. As the Scotch are a persistent people and Lieutenant Henn is said to intend to challenge again, while the Irish and Welsh are still to be heard from, it is probable the cup regattas will for some time give us an annual fête.

It will be noticed that in the eight contests for the cup seventeen separate races have been sailed. Of these our opponents have gained but one. In the meantime, though we have continued our lead in the matter of models, sails, and seamanship, keeping up our reputation of furnishing the best of everything for which we find a demand, the contests have been of great advantage to English yachtsmen, as their present vessels are a great improvement over those of 1851 both in model and sail plan.

At the meeting of the Association of Municipal and Sanitary Engineers held at Leicester in July, Sir Robert Rawlinson offered the sum of £10 for an essay upon the subject of sewer-

ventilation. At a recent council meeting of the association it was decided to form a committee to carry out Sir Robert Rawlinson's wishes, with power to make such inquiries and experiments as they might deem advisable. The following gentlemen have been selected as the committee: Boulnois, of Portsmouth; Clarke, of Brighton; Gordon, of Leicester; Laws, of Newcastle, and Reade, of Gloucester. These gentlemen will be glad to receive any information upon the subject which may be sent to them; and the attention of our readers is directed to the letter of Mr. Boulnois in another column.

THE ELECTRIC-LIGHT IN NEW YORK.

A RECENT number of the *City Record* gives an abstract of the proceedings of the Gas Commission of this city, whose duty it is to arrange for the lighting of the streets, public buildings, etc. The larger part of the report relates to the different bids of the electric-light companies for lighting the streets by electricity, and the final disposition of the matter.

In the first place, the form of contract has been prepared with great care. It does not contain those loosely-drawn specifications so characteristic of such documents, and which permit a company to furnish an arc-light of from 300 to 500 candles, with the assurance that it is of 2,000 candles. We are glad to see that the so-called French measurement of these lights receives no recognition whatever. The third specification of the contract relates to "luminous intensity." "Each lamp must give a light equivalent to that of not less than one thousand standard sperm candles," etc.

The photometric measurements are to be made on a Bunsen photometer, and the candle-power is to be determined at an angle of 40 degrees from the horizontal. After each observation the electric-lamp is to be revolved 90 degrees about its vertical axis and another observation taken, and so on until ten observations have been made, the average of all being taken in determining the candle-power. A gas, oil, or other lamp of at least 20 candle-power, the value of which has been determined by direct comparison with candles, is to be used as a standard light. The measurements are to be made with the globe removed. Each lamp must be operated at not less than 475 Watts in the arc. Provision is also made for the testing of the lamps; and in case the illuminating power is less than 1,000 candles, such lamps are to be paid for only in proportion to the light furnished.

If other cities would adopt a similar form of contract we should soon be rid of that most objectionable expression, "French measurement." While electric-light companies here will be obliged to give up their pet method of figuring the candle-power of their lights, especially in their dealings with the city, they will have some compensation from the fact that the candle-power is to be taken at an angle of 40 degrees instead of horizontally.

The awards made by the Gas Commission do not state the exact number of lights required, inasmuch as this can better be determined when they are in position. At the same time the following are about the number of lights awarded to each company, with the prices per lamp per night:

U. S. Illuminating Co.—About 325 lamps, at 50 cents; 38 lamps, at 40 cents; 15 lamps, at 24 cents.

Brush Electric Illuminating Co.—About 450 lamps, at 25 cents; 17 lamps, at 40 cents.

East River Electric-Light Co.—About 191 lamps, at 39 cents; 271 lamps, at 19.9 cents.

Mt. Morris Electric-Light Co.—About 15 lamps, at 40 cents.

Harlem Lighting Co.—About 116 lamps, at 24 cents; 12 lamps, at 50 cents; 7 lamps, at 60 cents.

American Electric Mfg. Co.—About 93 lamps, at 32 cents.

North New York Lighting Co.—About 26 lamps, at 40 cents.

At the August meeting of the German engineers in Leipsic, a paper was read by Engineer Busley, on "The Use of Fluid-Heating Substances for Marine Boilers." This paper is most thorough, and one that is opportune at the present time when so many are experimenting with natural oils for heating purposes. Those interested will find it in the weekly number of September 9 of the *Oesterreichen Ingenieure und Architekten Vereins*.

OUR ILLUSTRATIONS.

AN OLD COLONIAL HOUSE AT JAMAICA PLAIN, MASS.

RESIDENCE OF S. P. STAMBACH, HAVERFORD COLLEGE, PA.

HOUSE built of local graystone, rubble finish, pointed with cement. The second story contains five chambers, bath and dressing rooms. The third story has two chambers, children's play-room, large store-room and tank-room. Cemented cellar under all. All latest improvements in plumbing and sanitary arrangements. Hot-air heating, with open fires in all principal rooms of first, second, and third stories. Hardwood finish; butternut, oak, and chestnut throughout interior. Windows of main portion plate glass; electric bells, burglar alarm, and gas-lighting. The architect was Mr. Charles Balderston.

IN the course of the forthcoming International Congress on Hygiene at Vienna, from the 26th inst. to the 2d prox., papers will be read by Dr. Gartner, Professor of Hygiene at Jena University, on water tests for drinking and lavatory purposes; by Dr. Frankland, Dr. König, of Münster, and Dr. Müntz, of Paris, on purification of sewage discharge and the contamination of rivers thereby. The Waring and Shone systems of sewerage will be treated by M. Durand Claye, Engineer des Ponts and Chaussees, Paris; Major Humphrey, of Memphis; M. Clement, of Hotel Dieu, Lyons; Dr. Knauff, Professor of Hygiene, Heidelberg. M. Trelat and M. Gruber, of Vienna, will give papers on heating, lighting, and ventilation of buildings.

THE recent Manchester meeting of the British Association, Mechanical Science Section, was particularly important as regards the valuable papers read on electrical matters. Mr. W. H. Preece's paper on "Copper Wire" in reference to "Telephoning and Telegraphy" led, and was followed by a paper by Prof. G. Forbes on "Underground Conductors for Electric Lighting," who also read a paper on "An Electric Current Meter." The next paper was by Mr. Gisbart Kapp "On the condition of maximum work obtainable from a given source of Alternating Electromotive Force." Mr. C. H. W. Briggs read a paper by himself and Mr. W. H. Snell on "Alternate Current Dynamos and Transformers." The last paper for the day was by Mr. F. R. Upton on the "Tele-meter System," as invented by C. L. Clark, of New York. At the second day's session, Mr. E. W. Serrell, Jr., of New York, read a paper on "Reinforcing Electrical Contacts so as to increase their reliability." Mr. Killingworth Hedges read a paper on "A new form of 'Secondary Battery.'" Mr. F. Brew read a paper on "Underground Electrical Work in America."

It will be seen that America plays no unimportant part in the meetings of the British Association.

THE "Metropolitan Railway" is again exhaustively treated in a recent number of the *Genie Civile* by M. de N., who is an advocate of the elevated system having three principal points of train departure, or main stations, with lines circling the principal suburbs.

IN the last number of the *Chronique Industrielle* there is an interesting description of the hydraulic appliances, such as cranes, bridges, and other machinery, used on the quays of the Port of Havre. Two steam-motors are used for the compression-pumps, two accumulators, and four generators; these forming the plant which operates all.

WE learn from the *Journal of Gas-Lighting* that the French Government is about to expend a large sum in experimenting with the Duke de Feltre's scheme of using a windmill to drive a dynamo, which is to charge accumulators, and these are to supply the La Heve Lighthouse light.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

No. XXII.

(Continued from page 433.)

THE POTOMAC FLATS DREDGING PLANT.

AMONG the dredging-machines which are arranged to transmit the material raised directly to the place of final deposit, the Von Schmidt dredge stands prominent.

lower end is a plain foot-valve of 20 inches opening, with rubber seating, so as to retain the water in the pump when not in action. The upper portion of the vertical shaft is square and slides through the bevel wheel by which it is driven.

The raising and lowering of the suction and the cutters is done by the vertical chains shown in Fig. 82 and in plan in Fig. 81. These pass to sheaves in the ends of the quadrantal arms shown in Fig. 81, and are operated by the

winches attached to said arms. The whole quadrant (with the supporting-frame, pipes, gears, etc.) is revolved by a gear taking into the segmental rack, as partly shown in Fig. 82. By reference to Figs. 85 and 82 it will be seen that the suction-pipe joins the upturned end of the pipe leading to the pump, by a stuffing-box within which it is free to revolve horizontally. The quadrant, etc., are attached to this part of the suction and revolve around it as a centre through an angle of about 120 degrees. This allows a circle to be dredged of about 60 feet diameter. The scow is 100x50 feet, with 7 feet depth of hold. The diameter of the hood at the bottom of the suction and also that over the pump-buckets is 8 feet. There are two boilers each 68 inches diameter, 16 feet long, with 98 tubes $3\frac{1}{2}$ inches diameter, and steam-drum 40"x6'.

Two engines run the plows and are each 12x12 inches, running at 120 revolutions per minute. With these it is claimed that at Oakland, when discharging through 4,000 feet of 20-inch pipe, the capacity of the machine in blue clay was 10 cubic yards per minute. Two engines, each 22-inch cylinder, 20-inch stroke, with 100 revolutions and 85 pounds steam-pressure, run the pump.

Three of these machines are now in use at Washington. Some larger engines are being built for driving the pumps, and Mr. A. P. Broomell presented to the Engineers' Club of Philadelphia, at a meeting in March, the following description of them:

"These engines have 24x24-inch cylinders. They are exceptionally heavy and substantial, the bed-frames alone weighing close to five tons. They will be automatic cut-offs, using my patent valves and governor.* So far as I am aware, this is the first instance of using automatic cut-off governors of the single-valve type on connected engines. Since the shafts and runners of pumps wear out very rapidly, it is necessary to make all parts of the governor in halves so that they may be readily taken off for renewal of

* This governor is not used in the machine doing the work under Col. Hains at Washington.

This type of machine was used in the harbor work at Oakland, Cal., carried out under Colonel George H. Mendell, of the U. S. Engineers, and is now in use on the Potomac Flats at Washington, in charge of Colonel Peter C. Hains, of the U. S. Engineers. The contractors and owners are Messrs. Benson & McNee, now of Washington, D. C.

The illustrations are from drawings made by us from blue prints of the machine used at Oakland, Cal.

Figure 80 shows a general view of the dredge.

Figure 81 is a plan of the front half of the boat and apparatus, and Fig. 82 an elevation of the same.

Figure 83 gives details of the frame-work, the quadrant, and the other parts for supporting and moving the cutter and suction-pipe.

Figure 84 gives details of the universal joint used in the shafting, by which power is transmitted to the cutter.

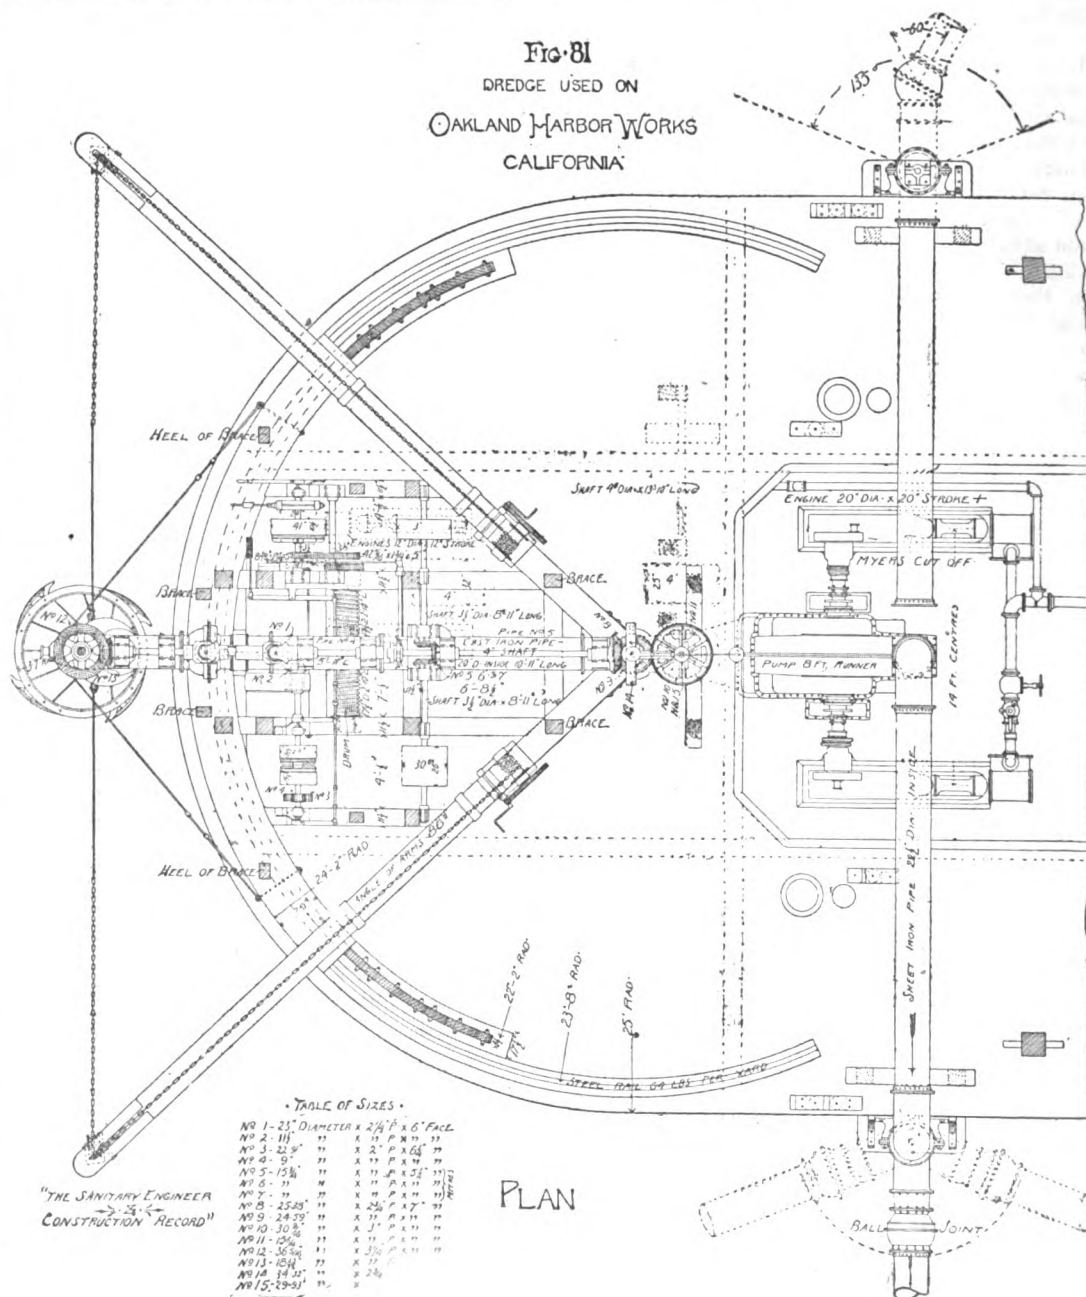

Figure 85 is the pump, etc.

Figure 86 shows the universal joints in the discharge-pipe, shown in Fig. 81, by means of which pipe the stream of water carrying the dredged material can be carried in any direction and to distances up to 4,000 feet.

Figure 87 shows the method by which the lower bend in the discharge where it leaves the boat is swiveled, so as to readily change the direction of the discharge.

The principle upon which the dredge works is to first cut up the material by a system of knives or plows attached to the bottom of a vertical rotating shaft. The plow consists of a horizontal circular iron frame or ring, attached by radial arms to the vertical shaft, to which ring heavy knives about two feet long are secured in a vertical position with the points downward. There are also four cutting knives fastened to the top of the same frame, with points upward revolving underneath the hood (to be described) for the purpose of cutting away material when from any cause the apparatus becomes too deeply engaged. The shaft passes down through the centre of a hood, surmounting the ring of cutters, and the suction-pipe has its lower end attached to the top of the hood, so that the mixed water and solid matter is drawn up by the pump and forced to its destination. Under favorable circumstances 25 to 35 per cent. is the proportion of solid matter to water; and from that down to 10 per cent, and even less. Boulders are passed up to 10 inches diameter, and of course all kinds of material of less weight.

The vertical portion of the suction-pipe is telescopic, so that work can be carried down to over 30 feet depth. At the

shafts. The requirements of this work are very severe on engines, the speed being 160 revolutions as a regular thing, and, at times, as much as 200 revolutions per minute. To prevent the engine working endwise at this high speed, it being attached only to the floor of dredges, is a pretty difficult matter. The plan I have adopted is a caging of heavy steel I-beams, firmly bolted and riveted together. We are making two pairs of these engines, as well as five smaller ones for these parties. A few of the leading sizes are:

"Crank shaft, of hammered steel, 13 feet long, 11 inches diameter. Main bearings, 17 inches long, babbet-lined. Crank pins, 6x6-inch, hammered steel. Piston-rods, cast steel, $3\frac{3}{4}$ inches diameter. Piston-heads have self-packing rings of cast iron. Steam-pipes, 6 inches diameter.

From a paper by Mr. Conway B. Hunt, read before the Engineers' Club of Philadelphia (see Proceedings, Volume VI., No. 2), we take the following additional items:

"The pump is a centrifugal one, of special design. The main chamber, in which the wings revolve in a vertical

plane, is eight feet in diameter and twenty-two inches in width. Its lower half is jacketed by an outer chamber through which the material is taken from the suction-pipe at the rim, and admitted to the pump at the centre through openings in the sides of the main chamber. The shaft to which the wings are attached is surrounded by a water-packing at its entrance to the pump-chamber, to prevent any leaking of air at these bearings and consequent impairment of the vacuum. The wings are six in number, and their radial direction is deflected away from the direction of their revolution. The pump is geared directly to the engine, which is double, with cylinders twenty-two inches in diameter and 24-inch stroke. They are run at 130 revolutions per minute, with a steam-pressure of 90 pounds at the boiler and cut off at one-half stroke, and their effective horse-power is rated at 200. The discharge-pipe leads off at a tangent from the main chamber of the pumps, and, after leaving the dredge, is carried to the shore on pontoons and thence to the point of discharge along the surface of the ground. It is of sheet-iron, twenty inches in diameter, and made in 32-foot and 16 foot lengths, the longer being used on the portion resting on pontoons, and the shorter ones on the shore section. The joint connections of the discharge-pipe are of rubber hose, two and one-half feet long and slightly larger than the pipes, over the ends of which they fit tightly and are secured by iron straps.

"The general operation of dredging is briefly as follows: The machine being secured in position by spuds, the suction-pipe is lowered to the bottom to be dredged, and the plows and pump are started, the latter being first "primed." The table is then swung slowly around the bow of the boat, the plows cutting a 9-foot swathe, two feet deep, and the shape of a semi-circle 60 feet in diameter, all the spoils being carried away through the suction as fast as dredged. By shifting the position of the dredge or lowering the suction-pipe, any desired size and depth of cut is obtained. The operator is guided in his management of the excavating apparatus by a vacuum gauge attached to the suction-pipe, which serves as an index of the proportion of mud or other material which is entering the suction. As the plow becomes too deeply engaged, this gauge marks a more perfect vacuum, and the reverse indicates a contrary condition. The consequence of admitting too large a proportion of solid matter to the suction is the clogging of the discharge pipe by the deposit of the surplus in its depressions and joints. The percentage of solid matter, which it is found best to admit to the suction, varies greatly according to the nature of the material. In dredging mud as high as 40 per cent. has been averaged, while in sand the percentage is much less. The efficiency of the dredge in hard material is noticeable, but it is not an economical machine for this class of work, on account of the large amount of water that must be moved in order to carry the material through the pipes."

"It may be noted, in conclusion, that the general requirements of a successful hydraulic dredge would seem to be, first, such a plow system as will excavate and thoroughly mix with water the material to be dredged and deliver it uniformly to the suction; second, a properly designed pump of sufficient power, presumably centrifugal, that will freely pass anything that can enter the suction, driven by an engine fully capable of developing the pump's best duty; and third, a general system of suction and discharge pipe which shall develop the least practicable frictional resistance, especially that due to bends. The numerous devices and details by which these requirements are attainable are, and necessarily will be, the subjects of various patents, and, as a consequence, their most efficient combination may be long deferred. The large number of machines that are still in the experimental stage of development would indicate that the best results attainable from hydraulic dredging machines have not as yet been accomplished."

In reference to the work done at Oakland, Mr. L. J. Le Conte, the assistant engineer in charge, states that the discharge was under a head of 14 feet above mean tide-level. The average discharge per month was 41,500 cubic yards of material, working 10 hours per day. The work for the last two months was 65,000 per month.

From a report by Colonel Hains on the Washington work, No. 1 dredge has discharged from 39,000 to 68,000 per month through 900 feet of discharge-pipe, and No. 2 has thrown as high as 90,000 yards through 1,200 feet of pipe. The longest pipe used up to date (September 22, 1887) was 3,500 feet.

WORKS, CAL.

RECENT WATER-WORKS CONSTRUCTION.

No. XIV.*

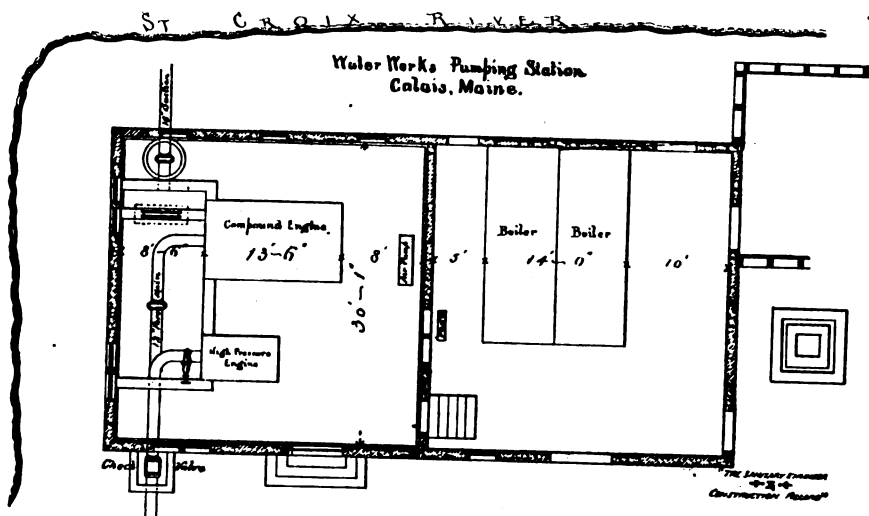

CALAIS, MAINE.

THIS, the most easterly city in the United States, is situated in Washington County, on the south bank of the St. Croix River, which is at that point the boundary line between this country and the provinces.

The city lies about eighty miles north-east from Bangor, is at the head of river navigation, has a population of over 6,000, and does a large business in lumber and ship-building, producing a million superficial feet of lumber per day, and building ten to fifteen vessels each year. A large fire in August, 1870, which burned over forty acres and consumed fifteen wharves and twenty vessels, together with other less disastrous conflagrations of later date, pre-

million gallons capacity (cost about \$10,000), with six miles of 4 to 12 inch pipe, 50 hydrants, and 90 gates in St. Stephens and Milltown, all owned by the St. Croix Electric-Light and Water Company.

The supply may be drawn directly from the river, or through a filtering-crib made of logs, built up log-cabin fashion 10 feet square by 12 feet in height, enclosing a circular open-jointed brick wall of 3 feet inside diameter, the space between the logs and well being filled with broken stone and gravel. Water-power, though abundant in the neighborhood, was not available for pumping, and two horizontal boilers, 66 inches diameter and 16 feet long, furnish power for two pumping-engines made by the George F. Blake Manufacturing Company, of Boston. The main engine is a compound duplex 14x28x14x18, of

pared the way for a public water-supply, which was introduced during the season of 1886 under the joint control of the Calais Water Company and the St. Croix Electric-Light and Water Company.

M. M. Tidd, Mem. Am. Soc. C. E., of Boston, was the consulting engineer, and the plans and specifications prepared under his direction included, on the American side of the river, the pumping-station, which is located on the river bank two miles above Calais, 14,484 feet of 12-inch pipe, 1,437 feet of 10-inch, 3,812 feet of 8-inch, and about 30,000 feet of 6-inch pipe, with 80 hydrants and 70 gates, and this portion of the double works is owned by the Calais Water Company. That portion of the works on the English side includes a reservoir of two

1½ millions capacity, and the reserve a high-pressure 1-million duplex 14x10x12.

The pumps force the water through a 12-inch pipe across a bridge at Milltown into the reservoir located on Todd's Mountain, in New Brunswick, at an elevation of 225 feet above high tide. The reservoir is rectangular in form, of earth, with clay-puddle walls, and in size is 184x151 feet inside at top and 133x100 feet on bottom.

The pipe on the American side was from the Warren Foundry, of New York; that used on the English side was cast at Glasgow, Scotland. All hydrants and gates were from the Chapman Valve Manufacturing Company, and J. J. Newman, of Providence, R. I., was the contractor for the entire work. The Calais works cost about \$78,000, and those of the St. Croix Company about \$30,000. Webster Lewis and Josiah S. were the company in both cases.

* No. XIII., the Water Works of Ware, Mass., was published on page 179, issue of July 16.

PAVEMENTS AND STREET RAILROADS.

No. XVII.

(Continued from page 490.)

WOOD PAVEMENT IN THE METROPOLIS.*

THE DISCUSSION.

IN the early part of 1882, when the pavement had been down less than five years, it became evident that its life had gone, and that it would have to be taken up. It had been his duty to take up the portion in Holborn in sections, in the years 1882-3; and not one block laid in 1877 was now to be found there. He might also mention, lest it should be thought that the circumstance had arisen from some want of care on the part of the officials of the Holborn District, that the portion laid down in the St. Giles's district as far as Tottenham Court Road had also been removed and relaid with Val de Travers asphalt. The wood pavement in Hatton Garden, which was considered a very suitable thoroughfare for the purpose, was laid in the Michaelmas quarter of 1878. It contained 4,679 yards superficial, and cost £3,743, or 15s. 6d. per square yard. It was laid in 1878, and yesterday, May 27, 1884, the Val de Travers Asphalt Company proceeded to take it up, and they were now laying down asphalt in its stead. With those facts before them he asked the members of the Institution to pause before they too readily endorsed the propositions of the author with reference to the economy of wood pavement.

Mr. W. E. Rich said, he thought the question asked by the President with reference to traction was most important. He believed that wood pavement was extremely favorable in regard to its low resistance to traction, and that was an important element which should encourage its extensive adoption. He hoped that some information would be forthcoming on the subject, obtained by means of the new dynamometer belonging to the Metropolitan Board of Works. He had himself had two hours' run with it a few months ago in some preliminary trials, and he had been surprised at the immense reduction in traction on going from a macadamized road to a wood pavement. He believed that the traction over a wood pavement did not exceed one half of that over a macadamized road, and it much less than that over a stone pavement.

Mr. E. Matheson inquired why the author had omitted all reference to asphalt. The paper seemed to imply that wood was the only alternative to macadam. Mr. William Haywood had exhausted the subject a few years ago, but he thought that later experience might induce him slightly to modify his views. In many respects asphalt was better than wood. The question of cost was not the only one to be considered. In regard to traction he had no doubt that asphalt was much superior to wood; but its alleged slipperiness had at first condemned it, and hindered its adoption. He believed it had been found that the difficulties connected with slipperiness had arisen from the inexperience of the drivers, and the strangeness of the new pavement to the horses. In Holborn, in the St. Giles's District, the wood pavement was about to be replaced with asphalt; and Cheapside also had an asphalt pavement. The low cost of cleaning, and the little delay in laying (an asphalt road being ready for use in twelve hours, while the author of the paper stated that wood pavement required a week), were important points in favor of asphalt over wood.

Mr. Hugh McIntosh said that he had not had sufficient experience to give a decided opinion upon the question in dispute. In his districts the authorities were only just beginning the use of wood. There were certainly some disadvantages connected with asphalt, with which he had made himself acquainted by observation and inquiry, and from which wood pavement was entirely free. The little experience he had had inclined him to favor wood in preference to asphalt.

Mr. J. Lovegrove remarked that only a very small area of wood pavement had been laid in his district. It was put down two years ago by the Improved Wood Pavement Co., and it had proved a successful piece of work. There were two rails passing through the centre of its width, and blocks of Guernsey granite, well dressed, were placed on each side of the rails. That was a very successful way of dealing with the difficulty of obtaining a comparatively noiseless pavement opposite a public building. They had had Val de Travers asphalt at first, but the rails and the asphalt did not wear well together. Some years ago he had made some experiments with a view of testing the cost of the maintenance of macadamized roads, and the result was that he advised his board that when the cost was found to reach 2s. per square yard, it was time to get rid of macadam and lay down wood or stone paving. There was a good deal of saving with wood and stone pavement in the matter of cartage, by far less mud being made than on macadamized roads. It was very important that all the information obtainable with reference to asphalt paving, pitching, and wood, should be laid before the members, and their thanks were therefore due to the author for his efforts in that direction.

Mr. A. Giles, M. P., considered that the author had not done justice to the subject of creosote in his statement when he said that creosote to a certain extent closed the fibres of the wood, and tended to produce premature internal decay. Mr. Giles had had great experience in creosoting, and this was the first time that he had ever heard of creosote tending to promote premature decay. It was quite true that the pickling process was worse than useless, but if the blocks, before being laid, were properly creosoted they

* A paper by George Henry Stayton, Assoc. M. Inst. C. E., and printed in the Minutes of the Proceedings.
† Minutes of Proceedings Inst. C. E., vol. lviii., p. 6r.

would last much longer than they did at present. It appeared from the statistics in the paper that the actual wear was only 0.144, or $\frac{1}{7}$ inch per annum. The average duration of wood pavement was six or seven years, and as the blocks were 6 inches deep, they only lost about one-sixth of their depth in the whole period of their life. The destruction of wood pavement was caused, not so much by wear as by decay, for every one must have noticed that when wood pavement was being taken up, a great deal of it was as rotten as touchwood. That would not occur if the wood were properly creosoted before being laid. He was sorry the author had not gone back to the early days of wood pavement in 1842, of which Mr. Giles had a lively recollection. It was nonsense to say that the slipperiness of wood pavement was only felt by inexperienced drivers, for there were certain states of the atmosphere when the pavement became so moist and greasy as to render it absolutely unsafe for horses. If something could be devised to prevent that slipperiness, a great benefit would be conferred upon the traveling public.

Mr. S. B. Boulton said that he had had considerable experience in creosoting, but not much in the application of that process to wood pavement. It would appear that usually the paving blocks were merely dipped in creosote, and perhaps sometimes in a mixture of that and other more doubtful substances. Was this a wise course to pursue? It was well known how much the creosoting process had been improved by the abandonment, for ordinary engineering purposes, many years ago, of the mere steeping tank, in favor of the cylinder process by vacuum and pressure. In one instance referred to by the author, that of the King's Road, the blocks appeared to have been prepared by the latter process. In this case only seven pounds of creosote per cubic foot had been injected. The "resources of civilization were not exhausted," however, by the injection of so small a quantity. The author had said that these blocks were, when taken up, moist internally, although it did not appear that they were unsound. The internal moisture could only have resulted from one of two causes, either that the wood was not dry enough at the time of creosoting, or that the quantity of creosote employed was insufficient to prevent the subsequent infiltration of water. Many engineers caused to be injected for railway sleepers and other timber, 10 pounds and 12 pounds of creosote per cubic foot. Even with these quantities the injection was partially superficial, but the creosote completely saturated the sap wood and softer parts of the timber, filling up all cracks and fissures, whilst the ends of the logs, for some inches up, were usually gorged with the creosote. Small pieces of timber like paving blocks should if prepared be saturated with creosote like the extremities of a sleeper. When timber was unprepared the ends of a log absorbed moisture freely; and this must be the case more especially with paving blocks. Moreover, it was not pure water to which the paving block was exposed. Ammoniacal products, the very class of substances which were used in experimental putrifying pits for hastening the decay of timber, were largely present in the moisture of the London streets. It spoke well for the paving blocks, and for the selection of the wood of which they had been made, that, unprepared or slightly prepared as they were, they had lasted as well as they had done. He was surprised to hear the author of the paper express the opinion that creosoting, by closing the fibres of the wood, tended to produce premature internal decay. General experience in this and other countries during the last forty-five years was entirely to the contrary. There had recently been exhibited at the institution a large collection of specimens of creosoted wood, sent by various railway administrations and from other sources, and which had been placed in many different kinds of soils. These specimens of ordinary creosoted fir timber had remained sound for periods varying from 10 to 32 years, and showed conclusively that the creosote, which had filled up the outer portion of the fibres, had completely protected the inner portion of the wood from decay. To produce such results it was of course necessary that the wood should be deprived of moisture, and that the creosote should be of a suitable kind. The wearing away of the top surface of the blocks appeared to be rapid; any decay of the woody fibre would doubtless accelerate this abrasion. Creosote had not only a preservative, but also a hardening effect upon timber, and if thoroughly injected could scarcely fail to prolong the duration of paving blocks. As regarded the kind of timber to be used, he thought that a greater variety might be tried. Gothenburgh had been spoken of, and excellent timber could be procured from that port, but no better than from various other Swedish ports, or from Memel, Danzig, or Riga. Beech he thought would do good service; it absorbed creosote remarkably well, and evidence had recently been brought forward of the very long duration of creosoted beech sleepers on the Chemins de Fer de l'Ouest in France. English elm also absorbed creosote readily, which was not the case with the American rock elm. He had recently taken three pieces of ordinary fir sleeper wood, three of English elm, and three of American elm, and had subjected them to the creosoting process under nine hours' pressure. The pieces of timber were all cut to the size of ordinary paving blocks, 6 inches by 6 inches by 3 inches. The results were:

AVERAGE QUANTITY OF CREOSOTE ABSORBED PER CUBIC FOOT.

	Lbs. oz.
Three pieces of fir.....	27 1
" " English elm.....	27 13
" " American elm.....	4 10

In forests through which he had traveled in Canada, the United States, Russia and elsewhere, he had noticed a great waste of timber in cutting the lengths for the ordinary purposes of the market. If some uniform standard of size for paving blocks were adopted in this country, and if it became known that there was a constant demand, much of this waste timber might be utilized by being cut into blocks, either in the forest or at the shipping port, whilst they could be brought here as convenient stowage for vessels at a very low rate of freight. He could remember some years ago when his offices were in King William Street, near London Bridge, the effect produced by taking up the granite pavement and substituting wood. No words can describe the sense of relief in the mitigation of the roar of a mighty traffic, which was at once experienced by all the busy toilers whose work had to be carried on amidst such surroundings.

(TO BE CONTINUED.)

SEWERAGE IN AUGUSTA.

THE report of the Board of Health of Augusta, Geo., for the year 1886 gives details of the work of sewer construction and repair which is going on in that city under the direction of the board, from which it is evident that a vigorous effort is being made to secure good and permanent work.

The President of the Board, Dr. Eugene Foster, calls attention to the fact that "every sewer and drain built by the board is part of a definite fixed plan and will not have to be rebuilt, as has been the case with fully eight-tenths of those built under the hap-hazard system of sewer building prior to the adoption of a complete plan for the entire city." Thus far none of the sewers built by the board have become clogged or have required manual cleansing.

The chief work during the year seems to have been the rebuilding and extension of the Macintosh Street sewer, amounting to 4,750 feet. The defects of grades, shapes, and depths of the old sewer are stated to have been such as to make it a curiosity, as well as a source of danger to the public health. Three thousand five hundred and eight feet of pipe-sewers were laid at a total cost of \$1,217.96, or a little less than 35 cents per foot. The reconstruction of the Macintosh Street sewer cost \$6,732.02. There is still plenty of work of the same kind to be done, for Dr. Foster remarks that of the 354 squares in Augusta, 250 have no contiguous sewer of any kind, and there are 5,689 surface privies in the city. The principal epidemic during the year was one of measles, of which it is estimated that there were nearly 3,000 cases. The estimated population is 36,000; whites, 20,500; colored, 15,500; and on this basis the death rate was, per 1,000: white, 16.48; colored, 33.86; total, 23.97.

FIRST REPORT OF THE OHIO STATE BOARD OF HEALTH.

THE State Board of Health of Ohio has issued its first report, which is for the year ending October 31, 1886, and thus begins another series of sanitary documents which it is to be hoped will be a long and important one. This first report is necessarily largely of an educational character, being intended to show the people what kind of work a State Board of Health might do, and what action is yet required on the part of the State to make it possible to do such work. The President of the Board, Dr. W. H. Cretcher, and the Secretary, Dr. C. O. Probst, both see very clearly that State sanitation to be effective must have a satisfactory system of registration of vital statistics, and it is plainly shown that at present the State of Ohio does not possess such a system.

It is truly stated that "it is of the first importance that a law be enacted requiring a burial permit for the interment of every dead body within the State. The permit should be obtained only from an authorized person, who, before granting the same, should demand and record all the facts required in connection with the death." There is no other way of obtaining the information which a State Board of Health must have if it is to do effective work. In his address the President lays stress on the inefficiency of voluntary aid in State sanitary work and urges legislation requiring every chartered village, town, and city within the State to maintain a local board of health. In this he is in accord with the experience of other State boards, which have found that among their most important duties are those connected with the local boards.

Dr. Cretcher also advises the appointment of a salaried health officer for every county in the State, an experiment which has not yet been tried, and which will probably not be tried unless the results of local board work are decidedly unsatisfactory.

The appendix to the report of the board contains accounts of some local investigations into sewerage, water-supply, pollution of streams, an epidemic of diphtheria, etc., all of which show the need for both local and central sanitary authority; and some educational essays on food adulteration, heating and ventilation, school hygiene, etc., which, it is to be hoped, will be read with profit.

The report by Dr. H. J. Sharp on the water-supply and sewerage of Bellaire shows that the inhabitants of that city have for some time been drinking diluted sewage, and it appears that there is a disease known as "Bellaire fever," which is probably a mild form of typhoid, and which would be one of the results to be expected, sooner or later, under such circumstances.

The volume also contains, as a supplement, the proceedings, addresses, and discussions at the State Sanitary Convention held at Warren, O., in March last, which was well calculated to arouse and educate public opinion as to the importance of sanitation.

INVESTIGATING WATER-SUPPLIES.

THE New England Water-Works Association has issued the following circular to its members:

NEW ENGLAND WATER-WORKS ASSOCIATION,
OFFICE OF THE SECRETARY,
NEW BEDFORD, MASS., September 21, 1887.

To the Members of the New England Water-Works Association.

GENTLEMEN: In the accompanying letter from Dr. Leeds a valuable opportunity is offered—viz.: to render such aid as may be possible in the study of the origin of tastes and odors affecting public water-supplies. Many of us possess information upon this point, and we should not forget that the smallest details may prove valuable. It is the desire of Dr. Leeds to obtain all possible assistance in this interesting and important research, and an earnest request is hereby extended that you will give that assistance by communicating to him every fact relating to the subject of which you may have knowledge. Yours truly,
R. C. P. COGGESHALL, Secretary.

STEVENS INSTITUTE OF TECHNOLOGY,
HOBOKEN, N. J., September 20, 1887.

R. C. P. Coggeshall, C. E., Secretary N. E. Water-Works Association.

DEAR SIR: At the Manchester meeting I was encouraged to believe that the members of the association would give such aid as lay in their power, in a study of the origin of the tastes and odors affecting most water-supplies. I have already collected considerable data, the information having been classified under the heads given below. Will you not request our members, at an early date, to send me similar data relating to their special work. In case the nature of the growth, etc., affecting the water is unknown to them, and they will express me a sample in a half-gallon preserve jar, I shall endeavor to determine it. By such co-operation I hope to be able to present to the association a paper of general value, and more especially of value to those who have given me their aid.

HEADS OF DESIRED INFORMATION.

- I.—Nature of tastes, colors, odors, and objections.
- II.—The years, times, and seasons of occurrence.
- III.—The related appearances, growths, organisms, temperatures.
- IV.—Sources of supply, amount, manner of collection, reservoiring and distribution, so far as they may possibly throw light upon the nature of the difficulties encountered.
- V.—Where the troubles have occurred—in collecting basins, reservoirs, pipes, dead ends. Their connection with stagnation at any point, shallow water, swamps, contaminations.
- VI.—Prior investigations and analyses, explanations given by yourself and others. Yours very truly,
ALBERT R. LEEDS.

A CORRESPONDENT gives the following regarding Chambersburg, Pa., Water-Works:

Works erected in the year 1882 at a cost of \$53,000, and the past year operated 361 days; average daily consumption, 392,441 gallons; daily average of coal, 2,724 pounds; pumping expenses, \$1,812.64; pipes laid, over 8½ miles; total amount of receipts, \$7,299.23 for the past year, and is now paying us a handsome revenue, and are taking up a bond of \$1,000 each year besides interest on investment.

UNDER a new method of making porous earthenware, lately used in Germany, the clay is tempered and worked to the proper consistency with a mixture of water and naphthaline. The objects, after being formed, are placed in a dry kiln and gradually heated until the naphthaline is expelled, leaving the object perfectly and uniformly porous. The dry kilns are so built that all the naphthaline is drawn off and condensed, so that it can be used over again.—*The Engineer.*

DOMESTIC ENGINEERING, ETC., IN THE
EQUITABLE LIFE INSURANCE BUILD-
ING, NEW YORK CITY.

No. I.

SKETCHES OF PLUMBING.

THE enlargement and alterations of the Equitable Life Insurance Company's principal building and offices in New York City are practically completed, and much of the details of the domestic engineering are nearly completed, and under which head we include heating, light-

(For Plan, See FIG. 1)

ing, water-supply, plumbing, elevator service, and all that goes to make up the engineering department of a great building, details and sketches of which we will give from time to time until they are completed.

FIG. 7

The plumbing of this building is on a grand scale, and in keeping with the magnitude and finish of the remainder of the building.

The plumbing fixtures of the building consist of 125 water-closets, public and private, about an equal number of urinals, 200 wash-bowls, besides slop-sinks, etc.

The general plan of the public toilet-rooms are shown in Fig. 1. There are two rooms to each floor, in opposite halls, with five closets, two wash-bowls, and two urinals, as shown, to each room. The walls, floors, partitions, and all but the doors and ceilings, are polished marble, except where the partitions are sashed and glazed. A good idea of a single closet-stall, with its partitions and doors, can be obtained from the sketch "A View in Toilet

rooms for the closets taper from three to four inches, with 2-inch branches to each bowl. One long cistern is used for all the closets of a room. They are copper-lined wooden boxes, with ball-cock and overflow, the whole encased in marble.

The ends of the soil-vent and local vent are carried around the end of the room within the thickness of a partition to the urinals and bowls, and clean-out screws are placed on the outside in such a manner as to give a clear rim for cleaning from the corners.

Ladies' toilet-rooms of the same general arrangements are provided for the female operatives and clerks of the building.

Figure 2 is a sketch of the rough work of a line of water-closets in the cellar, and gives a very good idea of

FIGURE 5.

Room." To the right of the figure in the ground plan is shown the relative position of the closets to the shafts through which the pipes and cables are run. These shafts are 4x8 feet, giving ample room for workmen to pass their whole length without going from floor to floor.

Within the shafts at the closet end are an 8-inch soil-pipe, a 6-inch back-air or vent pipe, and a local vent-pipe

the arrangement of details used throughout. This, however, in addition, shows a foot-vent of a line and a house-trap. The opening, it will be noticed, is within the thickness of the sidewalk arch. A grating, that can be lifted from the top, is used in the flag, and a pocket and cleaning-screw is used underneath the former as a receptacle for dirt or dust that may pass the grating and cap,

FIGURE 4.

of copper, which starts six inches in diameter at the lowest closet, and increases in size as it advances upward and receives more closet branches until it is twenty inches in diameter at the top.

The branches from these pipes pass through the walls of the shaft into the toilet-room. The soil-pipes are run beneath the floor in the usual manner, but the back-air and local vents are carried within a space formed by the marble lining of the room and the wall, as shown. The local vents are of copper throughout and taper, increasing in size from two inches at the first to six inches when it joins the upright pipe in the back-air

and the latter to facilitate its removal.

Figure 3 gives a very clear idea of the arrangement of the rough work for the urinals. A copper local vent is used as shown. The back-air pipes and traps are lead, and the waste-pipes iron.

Figure 4 is a view in the public lavatory showing range of wash-bowls, and Fig. 5 shows a single private wash-bowl in a corner of an office room.

Figure 6 shows the bowl in detail. The bowls are large and oval, 15x18 inches being the ordinary size used. The waste-pipes, vents and overflow-pipes shown are polished and plated brass, with ground union joints. The

joints of the overflow with the trap is screwed and sweated. The water-pipes and air-chamber are also polished brass, with special valve and fittings.

Figure 7 shows a slop-sink, as fitted at various places in closets on each floor. The sinks are heavy ceramic-ware, with brass flushing-rims. The legs and frames are also special brass castings. The waste, trap, and vent, which are shown in detail, are cast brass polished and buffed, and special brass bends are used on the waste-pipe behind the marble so as to give smoothness and an easy

flow to the water. Hot and cold water are supplied to these fixtures through a special combination faucet.

The master plumber is Mr. William H. Quick, and his local superintendent is Mr. John Kirkwood. Mr. George B. Post is the architect of the building.

Illustrated descriptions of the heating, ventilation, pneumatic service, elevator plant, etc., in this notable building, will appear in subsequent issues.

FIG. 6.

(See Fig. 7.)

Sectional view of slop-sink used in the Equitable Building.

ROUGH-WORK for URINALS

FIGURE 3.

FIG. 1.

CONTROVERSY OVER LETTING THE CONTRACT FOR STEAM-HEATING, ETC., OF THE NEW RAMSEY COURT HOUSE, ST. PAUL, MINN.

THE present delay and controversy over the letting of the contract for the steam-heating, boilers, etc., of the new Court House, St. Paul, Minn., is only the result of the idiotic habit of trying to let large work of an engineering character without a proper specification, and it is a matter that we have repeatedly drawn attention to.

In this case the architect made what might be called a "specification of requirements"—that is, he did not say what he wanted, but he told bidders what he desired to see accomplished and asked them to propose methods of doing it and say what compensation they would expect if he accepted their plan. The result of the matter was nine engineering firms made different plans and submitted them, with their bids, each, of course, considering their own plan the most suitable for the building.

So far, the programme followed a practice that is too prevalent, and, in fact, is the only one where an architect is not able to enter into the detail of what he wants to construct and is not desirous of calling to his assistance the talent and experience required to make a proper specification necessary to secure what his clients expect. In this case, however, the practice was somewhat changed when the contract was to be awarded, since the highest bidder was selected instead of the lowest. This, of course, was objected to by the remainder, who naturally thought their designs entitled to some consideration, especially as the lowest bid was only \$16,972, while the one accepted was \$37,358, and fully one-third more than the second bidder, who was only \$26,929.

The unsuccessful bidders very naturally remonstrated, and the consequence was the committee hesitated to let the contract on the architect's recommendation. A pamphlet on the matter now comes to us of eighty pages, which is an endorsement of the architect's recommendations, published with the view of influencing the committee.

The "specification" on which the work was to be let occupies thirty-four lines of this book, and the balance of the book, with the exception of a page or so, is given to the reports of the architect and two experts called by himself. They try to prove that his specification of thirty-four lines was all that it should be, and that the contract should be let to the highest bidder.

In justice to all parties and for a comprehensive understanding of the matter we quote the specification in full as follows:

REQUIREMENTS.

The steam-heater will figure separately for boilers and without them. He must state the number of horse-power for his boiler, and if furnished with mud-drums and steam-domes, and safety-valves, and glass-gauge and steam-gauge, and water-cocks; the size of flues, if any; of what material, how many hand and manholes; what kind of

grates; baffle-plates and rods, britchen, damper and clean-out door in same, and hatches of iron; what kind of steel in boilers, Black Diamond or Otis steel, how riveted, hand or machine, rests, dampers, and anything else to give a clear understanding of what the work will be, how boiler is set, with brick laid in fire-clay, thickness of walls, how much space taken, and a plate showing position of boiler, length and size; if Murphy's Oil Extractor is used: what kind of ferrules in flues, with collars; the kind of a return-tank, the kind of steam-pump to return water to boiler (make and size) and size of all pipes for supply for boilers; size of steam-pumps to run hydraulic elevators, two in number; size of supply and return from building, what kind of system used, what kind of radiators, how far apart the pipes, and how many in each radiator, what kind of screens, how painted or bronzed, if electric automatic attachment is provided for each radiator, what kind of cocks, Jenkins or otherwise, what kind of air-valves, what kind of fitting.

The number of feet of radiation, and what degree of heat they will heat, when it is 30° below zero, how long that they will warrant it, and at what pressure on the building will it have to be to gain the required result, and in what time they will complete the building after contract is awarded.

The contractor will have to do all of the cutting required, and patching and finishing complete that may be damaged by the execution of this contract, and will be compelled to give a guarantee that his work will do all that is claimed for it.

The work to be paid for every month, less fifteen per cent., and when the work is all done and completed and accepted as satisfactory, the per cent. kept back to be paid.

Further comment is not necessary from us, excepting that we suggest to persons who cannot write a proper steam specification, or those who will not, that a simple and, we think, a better way than the above would be to follow the style of a physician's formula, thus:

R. Ramsey County Court House.

Boilers, quantum sufficium.

Pumps, q. s.

Radiators, q. s.

Apply when it is 30 below zero.

LEX.

It certainly saves time at first, although the trouble is sure to come later.

The following analysis of the bids submitted as made by one of the experts called by the architect may prove interesting to architects and engineers, as illustrating the range of ideas and prices entertained by men (contractors) who cannot be objected to as experts, as they certainly would not be in a court of justice, and this very range of expert opinion is the most forcible argument that can be put forth as to why the architect should draw his own plan and specification and take the responsibility of it, for good or bad.

Proposal of Thomas Davis.—Sum named, \$26,929.

Heating surface involved, 22,120 sq. ft.

Four heating boilers, one high-pressure boiler; total, 342.4 H. P.

Remarks—Submits no plans. Specifications indefinite in many particulars, but excellent in others. Several items involved in the work left out altogether. Radiation 33 per cent. too low. Pipes run in the basement will destroy basement rooms. I concur in the remarks made by the architect in his report.

Proposal of S. I. Pope & Co.—Sum named, \$19,700.

Heating surface, 18,000 sq. ft.

Four boilers, aggregating 288 H. P.

Steam-main, 12-inch.

Remarks—No plans. Specification quite well drawn, but calls for a high-pressure system, using not less than 12 steam-traps. Pipes run in basement, to which the same objection as made before obtains.

Proposal of Allan Black.—Sum named, \$23,000.

Heating surface, 18,244 sq. ft.

Four 60-inch boilers, presumably 75 H. P. each.

Steam-main, 9-inch.

Remarks—For plans Mr. Black submits tracings in pencil with radiators penciled on in red, but the heating surface, boiler-power, and size of pipes are all too small.

Proposal of Kenny Bros.—Remarks: Messrs. Kenny Bros. present a bid for four 60-inch boilers 18 feet long, with 50 tubes 4 inches in diameter in each, and one boiler 44 inches by 12 feet, having 3-inch tubes in the same. Their bid for boilers is very complete, and, by far, the clearest of any submitted, but the bidder forgot to specify the size of any outlets or nozzles.

Proposal of Holland & Thompson.—Sum named, \$23,844.

Heating surface, 17,813 sq. ft.

Four boilers 60-inch by 16 feet, aggregating 308 H. P.

Steam-main, 8-inch.

Remarks—The system involved in this bid is high-pressure, using steam-traps. The pipes, boilers, and radiating surface are too small for a possible successful operation.

Proposal of William Rodger & Co.—Sum named, \$20,645.

Heating surface, 18,998 sq. ft.

Steam-main, 8-inch.

Remarks—High-pressure and steam-traps; requires no further comment.

Proposal of Osborne & Co.—Sum named indefinite.

Heating surface, 12,000 sq. ft.

Three boilers?

Steam-main, 5-inch.

Remarks—Not having a "Webster's Unabridged" at hand, am a little at loss to interpret just what a system having "hydrothermaton," "retroduction," "revertibly connected," "binately connected," etc., etc., may comprise, but it is evident it has something to do with "hydrothermaton," at least the specification does.

Proposal of C. H. Parmelee.—Sum named, \$16,972.

Heating surface, 13,000 sq. ft.

Three boilers.

Steam-main, 10-inch.

Remarks—Requires no comments.

Proposal of A. O. Nepil.—Sum named, \$37,358.83.

Heating surface, 28,000 sq. ft.

Steam-main, 14-inch.

Five boilers, 60-inch by 16 feet, aggregating 385 H. P.

Remarks—The sum named above in this proposal includes elevator pumps and piping, with tanks, and a system of hot and cold water, including tanks and hot-water boilers.

Correspondence.

All correspondents should send us their names and addresses, not necessarily for publication, but as a guarantee of good faith and because it is often necessary to communicate with them for additional information before printing their communications. Anonymous letters will not be noticed.

BOOKS ON SCHOOL ARCHITECTURE.

SIR: In reply to letter of Mr. William Duffus, in your issue of September 17, perhaps he refers to my little book on "Rural School Architecture," written for the United States Government, and published by the Bureau of Education at Washington, under the name of "Circular of Information, No. 4, 1880," which the Commissioner of Education of the province of Ontario has before been kind enough to notice with commendation. This can be obtained from the Bureau of Education, Washington, D. C. The work on City Schools must, I think, be one of the annual reports of the Massachusetts Board of Education, which contains a valuable monograph on the subject. I have not the book at hand, and do not recall the year, but, if it is not out of print, it may perhaps be had by addressing the Secretary of the Board at the State-House, in Boston.

Very truly yours, T. M. CLARK.

COMPARATIVE SANITARY CONDITION OF PRINCIPAL CITIES.

SANITARY DEPARTMENT,
1 Montrose Street, Glasgow,
September 22, 1887.

SIR: I observed in your issue of September 3 some figures published by Dr. Bertillon, of Paris, comparing the death-rates of various cities from zymotic diseases. I do not know where he obtained them, but so far as Glasgow is concerned I shall be obliged if you will kindly correct them. The number of deaths per 100,000 of the population from small-pox for 1886 was 0.4, not 68 as stated in THE ENGINEERING AND BUILDING RECORD. There were only two deaths. For diphtheria the rate was 18 per 100,000, and not 29 as stated.

I am, yours truly,
PETER FYFE, Sanitary Inspector.

SEWER-VENTILATION.

BOROUGH ENGINEER'S OFFICE,
PORTSMOUTH, ENG., September 20, 1887.

SIR: As a member of a Committee of the Association of Municipal Engineers appointed to investigate and report upon the subject of sewer-ventilation, I shall be much obliged if any of your readers will be kind enough to send me the results of any experiments they have made or any verified facts in connection with the subject.

The committee are anxious to obtain facts upon the subject rather than theories, so as to form a record or history of this important sanitary question, and I feel sure that if you will kindly give publicity to the requirements of the committee we shall be furnished with all that is known about sewer-ventilation upon your side of the water.

I am, sir, your obedient servant,
H. PERCY BOULNOIS, M. Inst. C. E.

HOT-WATER CIRCULATION FROM TWO BOILERS HEATED BY TWO RANGES.

SCRANTON, August 31, 1887.

SIR: Will you kindly inform me through your paper what I must do to make two boilers work together, with fire in both ranges, as I show on the cut? I remain as ever,
T. J. C.

Fig. 1

[You send us very little data to base a reply upon.

(1) You do not say whether your water-supply is from the street pressure or from a tank in the top of the house.

(2) You do not say whether the two fires are under the one control or not.

If each boiler and each sink belongs to different floors of an apartment or tenement house, then each should be supplied separately from any source whatsoever and have separate vent-pipes if from a tank supply. Otherwise serious complications may follow if one boiler is out of use, such as mixing hot and cold water through different pipes, etc. For instance, while drawing hot water at the lower sink, and the upper boiler only being in use, it would be found that cold water would pass from the cold boiler through what would be the hot-water pipe and mix with the hot water from the upper boiler on its way to the sink.

The only condition under which your two boilers can work together, as shown in your sketch, is when there is a fire in both ranges. Of course, stop-cocks may be put into the cold and hot pipes at the tops of the boilers to shut off the one that is not in use, but if this is done they will be forgotten sometime and disaster will follow.

Fig. 2

If your arrangement is required for a summer and winter kitchen, in which there is a fire alternately, or for a kitchen and laundry where both fires are under one control and run together, then you may fit them up as shown in Fig. 2. Take the cold supply to the lower boiler and connect the hot or flow pipe of the same with the upper boiler, entering it almost where you please. Then, when both are run together, as on a washing day, you can draw abundance of hot water from the upper one, as the water of both goes there, and on ordinary days you have the upper one alone. Should the supply be from the street a check-valve should be used in it near the lower boiler.]

Novelties.

BENDING PIPES.

We herewith illustrate a recent patent for a novel pipe-bending machine issued to James H. Kelly and Charles H. Broad, of Rochester, N. Y.

It looks to us as if this apparatus might be used by plumbers and others to good advantage in making bends in thin lead pipes of comparatively large diameter, and that for making $1\frac{1}{4}$, $1\frac{1}{2}$ or 2 inch pipe bends on the job it would prove serviceable.

It consists of a grooved form A, with a head B of the size of the bend and also grooved, and a clamp C.

D is a yoke pivoted on the axis of the forming head, and E is a die pivoted in the yoke, each part having a lever or handle, F, by which it is operated. The lower end of the die is grooved to fit the top of the tube or pipe.

G is a stirrup attached to the yoke and moving with it.

F is the rod or mandrel through the medium of which the bending is done. This rod may either be straight and of the same diameter its whole length, or it may have an

enlargement forming a head at the inner end, as shown in the drawing. The outer end of the rod rests in the stirrup, and is held to it by any suitable means, that shown in the drawing being a nut, H, which screws upon a thread on the rod, and thus serves as a gauge to adjust the rod forward or back.

To bend the tube or pipe, the same is secured on the form, the rod is inserted on in the projecting end of the tube or pipe, its end resting over the form, and the yoke, carrying the die, the stirrup, and the rod, is then swung around the form, the rod in that case causing a simultaneous drawing and bending movement of the tube around the form, and making the bend as it progresses, and the circular end or head, resting at the point where the bending takes place, forms a core to preserve the circle of the tube, and leaves it practically circular in cross-section its entire length.

Gas and Electricity.

Illuminating Power of Gas in New York City.

Week ending	New York Gas-Light Company.	Manhattan Gas-Light Company.	Metropolitan Gas-Light Company.	Mutual Gas-Light Company.	Municipal Gas-Light Company.	Kriegerbocker Gas-Light Company.	Equitable Gas-Light Company.

E. G. LOVE, Ph.D., *Gas Examiner.*

THE fifteenth annual meeting of the American Gas-Light Association will be held in this city on October 19, 20, and 21. The following papers have been promised, and others will doubtless be added to the list before the meeting: "Fuel-Gas," by Emerson McMillin, of Columbus, O.; "Illumination vs. Candle-Power," by Alex. C. Humphreys, of Philadelphia, Pa.; "Utilization of Residential Products," by Charles H. Nettleton, of Birmingham, Conn.; "The Advantages of Gas Companies Engaging in the Electric-Light Business," by E. J. King, of Jacksonville, Ill.; "Water-Gas," by Walton Clark; "Development of the Half-Depth Regenerative Furnace, and Some of the Results," by V. B. Webber, of New York; "The Comparative Illuminating Power of Gas Purified with Lime vs. Oxide of Iron," by C. W. Blodget, of Brooklyn.

WESTERN ASSOCIATION OF ARCHITECTS.

THE following circular has been issued: "The Western Association of Architects was organized to encourage the development and progress of architecture, and to establish uniformity of action and understanding among the architects of the West and South, so that their combined influence should tend to elevate professional standards throughout the country.

"Believing comparison and consultation to be among the best methods to induce interest in the growth of the profession, in behalf of the Board of Directors of the Western Association of Architects, we extend to you a cordial invitation to send to the committee in charge of the drawing exhibit at the Cincinnati convention such pencil or pen and ink sketches, water-color drawings, photographs, and models of a few of the buildings designed and executed under your supervision during the past ten years. It is the hope of the association that the exhibition at the convention will be in all its departments unusually full and widely illustrative, so that architects from all parts of the country, whether members of the association or not, will have an opportunity for a wide survey of work done throughout the country during this period of time. Your co-operation in this, which we believe to be a very important work, will be highly appreciated.

"The association will pay all costs of transportation to Cincinnati and return, as well as charges for boxing, shipping, hanging, etc.

"Should it be your pleasure to contribute to the exhibition will you kindly inform the Committee on Drawing Exhibit at your earliest convenience of the number and size of drawings you will send.

"The Western Association will also be gratified to have your presence and co-operation at the next convention, which we trust will be one of interest and significance."

JOHN W. ROOT, President,

115 Monroe Street, Chicago, Ill.

D. ADLER, Chairman Board of Directors,
58 Borden Block, Chicago, Ill.

J. F. ALEXANDER, Secretary,

Corner Fourth and Main Street, Lafayette, Ind.

The Western Association has also issued a similar invitation on behalf of the American Institute of Architects, the convention of which is to be held in Chicago, beginning October 19 next. Drawings or photographs for the American Institute of Architects' Exhibition should be sent to Henry Lord Gay, Chairman of the Committee on Drawing Exhibition, 15 East Washington Street, Chicago, Ill. The American Institute of Architects will pay all costs of transportation, boxing, etc., to Chicago and return.

ILLINOIS STATE ARCHITECTS' ASSOCIATION.

THE annual meeting of the Illinois State Association of Architects was held October 1. The Executive Committee reported the arrangements made for the reception and entertainment of the American Institute of Architects, which will hold its twenty-first annual convention in Chicago October 19, 20 and 21. The headquarters will be at the Leland Hotel.

The election of officers for the ensuing year resulted as follows: President, Samuel A. Treat; First Vice-President, L. D. Cleveland; Second Vice-President, Clarence L. Stiles; Treasurer, H. W. Hill; Secretary, R. C. Berlin; Executive Committee, the President and L. H. Sullivan, John W. Root, Alfred Smith, and W. W. Clay.

AMERICAN SOCIETY OF CIVIL ENGINEERS.

THE third fall meeting was held October 5, Mr. W. E. Worthen in the chair. The meeting was principally devoted to business of the society.

Mr. J. P. Davis presented a resolution for the appointment of a committee to consider and report an amendment to the constitution relative to the mode of electing members.

This resolution was discussed by Messrs. Davis, Wellington, Dorsey, North, Bogart, O'Rourke, Croes, and Brinckerhoff.

After a lengthy discussion the resolution passed, and the President appointed on the committee Messrs. Davis, Wellington, and Paine.

A report was received from the committee appointed at the last annual convention to consider and report on the advisability of creating the grade of Student in the society. This report was referred to the committee for further consideration and to report.

The report was discussed by Messrs. Croes, Paine North, Bogart, Davis, and Wellington.

A statement of excessive rainfall was made by Mr. William Rumble, which occurred October 30, 1866, at Morrisania. Rain had fallen during the previous night. The following day the rain fell from 7:45 A. M. until 9:15 A. M. to a depth of $1\frac{1}{8}$ inches, which is at a rate of $1\frac{1}{8}$ inches per hour.

At 10 A. M. there was running in Mill Brook at the railroad crossing 100 cubic feet per second, or 360,000 cubic feet per hour. The area of Mill Brook water-shed above the point of measurement is about 1,790 acres, and the amount of rainfall on this area at the above rate will equal 7,472,355 cubic feet per hour. The quantity given as running in the stream would amount to about $4\frac{1}{4}$ per cent. of the net fall.

The following were elected:

For Members.—Henry St. Leger Coppee, Civil Engineer, Vicksburg, Miss.; Henry Clay Derrick, in charge of preliminary surveys Lynchburg, Halifax, and North Carolina Railroad, Halifax Court-House, Va.; Joseph Norton Greene, Chief Engineer and President Maine Shore Line Railroad, Willimantic, Conn.; Edward Buckingham Guthrie, (Elected Associate September 3, 1884,) Deputy City Engineer, Buffalo, N. Y.; Charles Edward Hewitt, (U. S. Military Academy 1880,) Engineer New Jersey Steel and Iron Co., Trenton, N. J.; Wynkoop Kiersted, (Rens. Pol. 1880,) engaged in general engineering work and designing water-works for Falls City, Neb.; James Imbrie Miller, Principal Assistant Engineer in charge of Northern District New Croton Aqueduct, Tarrytown, N. Y.; Palmer Chamberlaine Reckets, (Rens. Pol. 1875,) Engineer of bridge over Genesee River at Rochester, N. Y., for Rome, Watertown, and Ogdensburg Railroad, and Engineer of bridge for Monroe Co., N. Y.; Granville Wheaton Shaw, U. S. Assistant Engineer in charge Improving Falls of Ohio River at Louisville, Ky., and enlargement of Louisville and Portland Canal, Louisville, Ky.

For Associate.—Gratz Mordecai, Expert of U. S. Bureau of Labor, Washington, D. C.

HOT-WATER SUPPLY.*

THIS is a practical treatise by a practical man upon the fitting, etc., of hot-water apparatus for domestic purposes and general use, and is an exposition of modern practice in dwellings, etc., in London and elsewhere in England, and must prove of interest to American plumbers who are desirous of knowing all they can of the practice in Great Britain.

It makes no scientific pretensions, but gives considerable practical data as to sizes, etc., to be used, gives opinions on what, in the estimate of the writer, should be used, and points out objectionable features that should be avoided. It is well illustrated, and contains several full-page illustrations of house plans, etc., and systems showing how a few rooms or the conservatory of a house may be warmed from the kitchen or domestic boiler. It cautions the fitter or user, however, against placing too much reliance on these little heating apparatus, and points out the fact that a conservatory thus warmed is likely to be left without heat in the night-time, and just when it is most required. He also adds: "Coils can be, and are, worked from hot-water supply services at all times, but the general results are not altogether satisfactory, as the boiler (water-back) must be increased in power considerably to compensate for the loss of heat, and in summer annoyances experienced by the boiler (water-back) overdoing its work, etc." This journal in its Correspondence columns, has pointed out just this difficulty to American readers who try to successfully warm part of a house from the water-back of the kitchen-range. It is evident, from a perusal of this little work, that the author has had intimate practical experience with his subject.

PERSONAL.

MR. W. H. BRINCKERHOFF, M. Am. Soc. C. E., has accepted a position on the editorial staff of THE ENGINEERING AND BUILDING RECORD.

MR. JOHN BOGART, Secretary of the American Society of Civil Engineers, was recently unanimously nominated by the Democratic State Convention for the position of State Engineer and Surveyor of New York. It is understood that Mr. Bogart has declined the nomination.

CAPTAIN LAFAYETTE E. CAMPBELL, U. S. A., has been ordered to Denver to take charge of the construction of the military post near that city.

MR. EDWIN THACHER, Chief Engineer of the Keystone Bridge Company, has accepted the position of Chief Engineer to the Decatur Bridge Company, recently organized at Decatur, Ala., and will proceed to his new field in a few weeks.

* A Practical Treatise upon the Fitting of Hot-Water Apparatus for Domestic and General Purposes. By F. Dye. E. & F. N. Spon, 125 Strand, London, and 35 Murray Street, New York. Price, \$1.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITIONS.

JERSEY CITY, N. J.—The Building Committee of the Board of Freeholders has awarded the \$300 premium for the best set of plans for the proposed Hall of Records to L. H. Gaile. It was also resolved to recommend the board to allow Digon & Co. and Anderson & Sailer \$75 each for the plans prepared by them.

ENGINEERING COMPETITIONS.

WILLIAM POTTS, Chief Examiner, will hold an open competitive examination for assistant engineers, levelers and rodmen at the rooms of the American Society of Civil Engineers, No. 127 East Twenty-third Street, New York City, on October 18. Written applications of candidates shall be made on or before October 12, to the Secretary of the New York Civil Service Commission, Albany, N. Y., who will furnish to applicants such further information as may be necessary. The examination is only open to citizens of the State who have been residents for at least one year.

For works for which proposals are requested see also the "Proposal Column," pages 505-507-511-512.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE ENGINEERING & BUILDING RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

WATER. SEWERAGE. ETC.

SODOM DAM, NEW YORK.

The plans for the Sodom Dam work have been adopted by the Aqueduct Commissioners and the specifications for the work will be ready during the first part of next week.

OMAHA, NEB.—The water-works is making considerable extensions of mains.

BEALTON, CAL.—Water and gas works will be constructed here by a stock company.

DEPOSIT, N. Y., September 30.—Our correspondent writes: "This village is supplied with first-class water-works. A little over two years ago a stock company was formed here, and the gravity system adopted. A large reservoir was built one and one-half miles from village. The place is supplied with an abundance of good water, with a head of about 150 feet."

ORLANDO, CAL.—Our correspondent writes: "There has been considerable talk on the question of irrigation in Colusa and Tehama Counties, but no immediate action has been taken in the matter until this month, when an election was held in a district formed of the north part of Colusa and a small part of Tehama, representing about 14,000 acres, for the purpose of irrigating the same from Stoney Creek. The irrigationists were successful, and we think work on the ditch will soon be commenced."

MONTPELIER, VT., September 30.—Our correspondent writes: "This town has established excellent water-works within the last three years, taking water from a large pond (or lake) about four miles distant, and voting, at a meeting held this week, to lay a second line of pipe to the reservoir, about three miles, I think."

LOS ANGELES, CAL.—City Council has passed an ordinance providing for the construction of \$1,000,000 of sewers.

DETROIT, MICH.—The Board of Water Commissioners have ordered the laying of much water-mains.

NEW BEDFORD, MASS.—Our correspondent writes: "Nothing is being done towards the establishment of water-works in this city. Water-works were established, and have been in operation, for nearly twenty years."

SAN JOSE, CAL.—City Council, September 26, adopted specifications for about one mile of sewers.

PITTSBURG, PA.—A large amount of sewer-work is projected. Address the Board of Viewers.

BROCKTON, MASS., is considering the advisability of doing about \$19,000 of sewer and drainage work.

TEMPLETON, CAL., will have a water-supply, taking water from Salinas River.

BOSTON, MASS.—Mayor O'Brien has just sent a message to the City Council urging the construction of certain sewers, to cost \$130,000.

SANTA ROSA, CAL.—T. J. Brooks and J. B. Davis and associates, of Santa Rosa and San Francisco, have taken up 4,000 inches of water of Mark West Creek, to be used for family and irrigation purposes in the city of Santa Rosa. The water is to be brought in iron pipes.

KUTZTOWN, BERKS CO., PA.—A company is being formed here for the purpose of building water-works.

HAYWARDS, CAL.—Address Col. William Haywards or Chisholm & Farrell about proposed water-works here. A company has been organized to erect water-works. It is expected that the enterprise will be pushed to rapid completion.

TUSCUMBIA, ALA.—Organized is the East Sheffield and Tuscumbia Water Company with a capital stock of \$50,000, and the following board of directors: W. S. White, Ed. B. Almor, C. D. Woodson, John A. Steele, A. H. Keller, Robert Cloud and Henry B. Tompkins.

ST. PAUL, MINN.—McRitchie & Nicol, of Chicago, are the contractors for laying the water main across the river at State Street.

ANNISTON, ALA.—Plans and specifications for a system of sewerage for the thickly inhabited part of the city were submitted to the Council September 29 by City Engineer Ott. The work is to be done by contract.

GREENSBORO, N. C., October 3.—Our correspondent writes: "Contract for water-works at this place has not been let yet."

NORTH EASTON, MASS.—Town meeting October 1 voted to increase the water-supply at a cost of \$15,000. A. A. Gilmore should be addressed.

LAKE, ILL., proposes to have a good sewerage system constructed. Address the Town Clerk.

KEOKUK, IOWA.—City Engineer Eimbeck has made a report to the Finance Committee showing the need of new sewers, to be constructed at a cost of \$50,000 to \$60,000. The matter is urgent, and, it is believed, the sewers will be built.

SHELL LAKE, WIS., September 30.—Our correspondent writes: "It is only a little talk for the present about water-works. It looks as though there should not be any this fall. If any to be I will let you know."

SAN DIEGO, CAL.—The Development Company, of San Quentin, Lower California, and the Land and Town Company, also of San Quentin, are organized to build up towns, construct water-works, etc. J. D. Hanbury, of Hanbury & Turrey, San Diego, is interested in both companies.

SUNVIEW, COL.—The Sunview Reservoir and Ditch Company has filed articles of incorporation. The company proposes to construct ditches and reservoirs on Little Fountain and Rock Creeks in El Paso County; trustees: Eliza G. Womack, Samuel R. Womack, and Theodore H. Lowe are named.

VINEYARD HAVEN, MASS.—Our correspondent writes about water-works: "Works in full blast; stand-pipe and wells nearly finished; pipes being placed and houses being plumbed fast."

MACHIAS, ME.—A town meeting has been held to consider the obtaining of a water-supply from a pond in Marshfield, at a cost of \$25,000.

ORANGEBURG, S. C., contemplates enlarging its water-works plant.

TARENTUM, PA.—Our correspondent writes: "The only water-supply is piped from several large springs and supplies about 300 families. There is a company here that have a charter, and it is recorded, and that is as far as they have gone. It will be some time before they begin operation."

HUDSON, N. Y.—The contract for building the State Street sewer has been given to Brennan Bros., at \$5,945.

LODI, CAL.—Bids were opened at Lodi recently for completing the Mokelumne Ditch and Irrigation Company's dam, near Burson, Calaveras County. The contract was awarded to Walker & Merwin, of Chico, for \$17,072.

CORPUS CHRISTI, TEX.—The American Well Company has submitted two propositions for the sinking of an artesian well—first, guaranteeing a flow of 50,000 gallons every twenty-four hours, sinking the well until the required amount of water was secured; in case the well would not flow, to furnish a boiler and relay pump, assuming all risks in consideration of \$15,500. Second, to sink one or more wells to a depth of 800 feet, until a 50,000-gallon is secured, at \$10 per foot.

NORWAY, WIS.—The town has undertaken a great drainage scheme in the swamps of Wind and Muskego Lakes. A canal will be constructed. Total cost estimated at \$400,000.

WORCESTER, MASS.—Address Major Winslow about the proposed introduction of filtering processes for the sewage. A committee has been appointed to consider the matter; immediate attention necessary.

LANSINGBURG, N. Y.—Engineer Franklin has prepared plans for a new reservoir for the water-works. The Water Board will take action at the next meeting.

SPRINGFIELD, ILL.—City Council has before it a plan for enlarging the water-supply with new galleries, etc., on the Sangamon River.

BOWLING GREEN, O., voted October 4 on the introduction of a supply of water.

BROOKFIELD, MASS.—Town meeting October 4 appointed a committee to obtain plans and estimates for a water-supply. Address the Town Clerk.

DUBUQUE, IOWA.—City election went against the proposition of City Council to raise funds for a sewerage system, and the matter will be dropped.

RICHFIELD, KAN.—Address F. F. Stevens about a new water company here.

FORT COLLINS, COL.—Sewers will be built here.

BROOKLYN.—Chief Engineer Van Buren has submitted his report on relief sewers to the Department of City Works. The estimate is \$149,000.

CHICAGO, October 4.—The City Engineer is about to advertise for bids for the construction of the new water tunnel, extending four miles into the lake. The tunnel will be eight feet in diameter, four miles in length, will cost about \$600,000. There will also be additional pumping-engines, to cost about \$500,000.

KINSLEY, KAN., has contracted for the building of water-works.

WAYCROSS, GEO., will obtain a supply of water from artesian wells. The contractor is T. M. Dexter, of Brunswick.

RALEIGH, N. C.—On report of Professor J. L. Ludlow, the water-works have been accepted by the city.

SYRACUSE, N. Y.—Bids for constructing sewers were opened by Common Council September 26. The lowest bidders were Martin & Sprague, \$22,125.56, for the James Street sewer, and Hugh Purnell, \$4,687.50 for the Gifford Street sewer.

GRIFFIN, GEO., wants water-works.

LOS PASOS, CAL.—The Los Pasos Land and Water Company has been incorporated; Thomas R. Bard, Dan McFarlane, and others.

WATER-WORKS are projected in the following towns: Greeley, Col.; Pontiac, Mich., \$75,000; Georgetown, Ky.; Westboro, Mass.; Montpelier, Vt., \$30,000; Ortonville, Minn., \$10,000.

BALTIMORE, MD.—The Consumers' Water and Illuminating Co., capital stock, \$200,000, has been chartered to supply Woodberry, Hampden and vicinity with water and gas. The directors are Jeremiah D. Mallory, Richard J. Capron, William M. Busey, George B. Morton, and William H. Watkins.

CLEVELAND, O.—City Council will appropriate \$5,000 for topographical maps for the work of purifying the Cuyahoga River.

GREENSBURG, PA.—The Westmoreland Water Co. will receive bids until the 17th inst. for the construction of water-works in Greensburg, Pa. For information address George H. Fox, Secretary, Kittanning, Pa.

MCKEESPORT, PA.—Mr. Joseph Ecoff, Superintendent of the water-works writes: "Water-works were established in this city in the year 1882 and have been in successful operation ever since, but now, owing to the large increase in population, the demand upon the works is so great as to call for much larger pumping capacity. The present pumping capacity is 3,000,000 gallons, which comprises two 1½ million gallon high-pressure 'Worthington' engines, and it is now proposed to increase the above by the addition of one 5,000,000 gallon compound condensing engine, for which bids were opened by our water committee on September 22, but as the matter at this date has not been decided it is still a question as to which particular engine will be erected. It is expected to publish the result of the letting in due time."

FAR ROCKAWAY, L. I.—It is probable that conclusive steps will shortly be taken towards a complete system of sewerage for this place.

GREENBUSH, N. Y.—The specifications and plans for \$10,000 of sewer work are before the Sewer Commission. Address the City Clerk.

EAST TAWAS, MICH.—Water works will be erected here by a firm of contractors from Grand Haven, Mich. The bid was \$48,000.

GREENVILLE, MICH.—A Special election will be held here October 12, to settle the water works question.

MT. PLEASANT, IOWA.—The American Trust and Loan Company has bought the Mt. Pleasant water works.

EASTON, MASS.—A meeting of the North Easton Village District Association is to be held, to determine whether the district will appropriate money for the extension of the water works.

HARRISBURG, PA.—A number of small water companies in the Philadelphia suburbs have filed notice of large increase in their capital stock, as follows: Lower Merion Water Company, from \$1,000 to \$500,000; Haverford Water Company, from \$1,000 to \$100,000; Radnor Water Company, from \$1,000 to \$100,000.

MILWAUKEE.—Water-mains will be laid in Sixth Street from North Avenue to Lee Street, also in Highland Boulevard from Washington Avenue to Twenty-ninth Street, two blocks. Water-meters are being put in here in great numbers in stores and public places. The Legislature last winter passed a law making the use of meters in public places and stores compulsory, and the Water Department is serving notices as fast as the meters arrive.

MILWAUKEE.—A pipe sewer will be laid in Twenty-first Street from Chestnut Street to Cold Spring Avenue, one block. A brick sewer in Mitchell Street, from Bismarck Avenue to a point twelve feet west of Eleventh Avenue.

PITTSBURG, PA.—The Controller has just advertised for new water-pipe.

KYLE, TEX.—The Kyle Water Company, capital stock \$15,000, has been incorporated for the purpose of building water-works.

CHARLOTTE, N. C.—Correspondence is invited by the City Council in regard to a system of water-works.

MARIETTA, GEO.—A proposition has been made by Proctor Lawrence to erect a system of water-works.

CHARLESTON, S.C.—The Charleston Water-Works Co. will erect an additional reservoir with a capacity of 5,000,000 gallons. The new reservoir will be about 200x250 feet and 15 to 18 feet high.

GAS AND ELECTRIC-LIGHTING.

BALTIMORE, MD.—Incorporated is the Waterhouse Electric Company, of Baltimore, to erect electric-light plants. Robert R. Zell, William R. Pope, and others.

NEWARK, N. J.—The contract for furnishing lamp-posts has been given to Mayher, Robinson & Flockhart, at \$5.10 per post.

BOWLING GREEN, KY.—The City Council of this city has appointed a committee to-night to advertise for bids and contract for the construction of the necessary works for the lighting of the city with electric-light. H. E. Jenkins is chairman of the committee.

LITTLE ROCK, ARK., is negotiating for electric-lights in the streets. Address Mayor Whipple.

LEWISTON, ME.—On September 29 the Board of Aldermen awarded the contract for lighting the streets to the American Electric Manufacturing Company, of New York City. 100 arc-lights, of 200 candle-power each, will be erected.

BAY CITY, MICH., is receiving proposals for lighting the streets with gas and electric-lights.

LEWISTON, ME.—The question of lighting the streets of the city to the exclusion of gas has finally been settled. At a recent meeting of the Board of Aldermen and Common Council, bids from ten different electric-light companies were considered, and resulted in the contract being awarded to the American Electric Manufacturing Co., of New York.

GAS-LINE.—The contract for laying forty miles of gas-mains for the Bridgewater, Pa., Gas Company has been given to George Free.

SAN FRANCISCO, CAL.—The Standard Gas-Light and Fuel Company, of San Francisco has filed articles of incorporation. The capital stock is \$3,000,000. The incorporators are Henry McGurran, William B. Cluff, James D. Boyer, B. B. Duncan, and William F. Harris.

EAST ORANGE, N. J.—The Edison Illuminating Company, of Orange, has asked for a franchise permitting the company to lay wires and establish plant for electric-lighting.

COLUMBUS, O.—The Columbus Electric-Light Company has made a proposition to City Council to erect and maintain lamps at \$93 each per annum. No action has yet been taken. Address Councilman George E. Hardy.

DOUGLASS, WYO. T.—The Wyoming Oil and Mining Company is incorporated; capital, \$1,000,000.

POMONA, CAL.—Articles of incorporation have been filed by the Pomona Gas and Electric-Light Company. The directors are H. A. Palmer, J. E. Packard, James T. Taylor, O. F. Griffin, Charles French, C. C. Olmstead, and G. W. Lynch.

JERSEY CITY, N. J.—Bids for lighting the streets were opened September 30, as follows: The United Improvement Company, gas, 925 lights in old Jersey City and Lafayette, \$18 per lamp yearly; 1,225 lamps in old Bergen and Hudson cities, \$19.50 per lamp yearly; 125 lights in Greenville, \$25 per lamp monthly.

The New York and New Jersey Globe Gas Light Company, 1,000 to 1,500 naphtha gas lamps, at \$1.62½ per lamp monthly.

The Jersey City Electric-Light Company, 40 electric lamps, at 40 cents per lamp per night, or 33 cents if the lamps are lit every night in the year.

No action is yet taken.

HYDE PARK, MASS.—The town has contracted with the American Electric Manufacturing Company to light the streets at \$70 per lamp per annum.

CORPUS CHRISTI, TEX.—An electric-light company will be soon organized here to light the streets.

ORANGE, N. J., has granted a franchise to the Edison Illuminating Company to erect a plant for street lighting.

SANFORD, ME.—Incorporated is the Sanford Light and Water Company, to operate electric-lights in Sanford.

ANTIGO, WIS.—A company has been formed here, with \$10,000 capital, to erect electric street-lights.

ROCHESTER, MINN.—The city has granted a franchise to the Electric-Light Company, and work on plant will be begun at once. Charles Streeter, Superintendent of Water-Works, can give further information.

RED BANK, N. J.—An electric-light plant for streets is wanted here. The town is ready to grant franchise to proper parties.

BRATTLEBORO, VT.—An electric-light company has been organized here.

AMSTERDAM, N. Y.—The city has made a contract with the Edison Electric-Light Company to erect 67 arc-lights of 2,000-candle power each.

ONEONTA, N. Y.—The Oneonta Electric-Light and Power Company has been organized to erect plant for street-lighting. Address Sawen & Connant for particulars.

PORTLAND, ME.—The Committee on Streets and Lamps will make contracts for street-lighting, etc.

TORONTO, ONT.—The Committee on Street-Lighting reports as follows: The plant by the Bell Electric-Light System would cost \$10,000, and the annual current expense \$4,000; this would give 50 street-lights at a cost of 50 cents a night, and allow of 25 shop-lights at 25 cents per night. The Toronto Electric-Light Company tender at 55 cents per light for 2,000-candle-power lights, with an electro-motive force of 45 volts. If the city and town lamps combined reach 200, a reduction of five cents per light will be made. The gas company tender for three years with burners consuming 3½ cubic feet per hour, each lamp to cost \$20.50 per annum, provided the company has a monopoly of the lighting; 100 Lambeth lights, burning 25 cubic feet per hour, 150 candle-power, at \$73 per lamp, or 20 cents per night. The matter was referred.

AMSTERDAM, N. Y.—The Common Council has decided to erect sixty-seven arc lights of the Thomson-Houston electric system in the streets. The cost is \$6,683.25 per year for sixty-seven lights of 1,200 candle-power each.

PATERSON, N. J.—The Paterson Electric Light Company has decided to establish the incandescent light system and supply houses and business places all over the city. Provisions for 3,000 lights will be made immediately.

SPRINGFIELD, ILL.—An incorporation license has been issued by the Secretary of State to the Peru Electric-Light and Water Company, at Peru, Ill.; capital stock, \$8,000; to furnish water, steam, and electric-power. Incorporators W. K. Hoagland, Theodore Wiberling, and William E. Moore.

MEMPHIS, TENN.—The Equitable Gas-Light Co. have purchased 25 acres of land outside the city limits, at a cost of \$50,000, upon which they will erect their plant and residence for mechanics.

WILMINGTON, N. C.—The Wilmington Electric-Lighting Co. contemplate enlarging their plant.

STAUNTON, VA., have enlarged their electric-lighting plant. Address John I. Long.

PINE BLUFF, ARK.—The old gas-works are being replaced by the South-western Light and Improvement Co. A number of new gas-mains will be laid.

PINE BLUFF, ARK.—An electric-light plant is contemplated.

AUGUSTA, ME.—The Kennebec Light and Heat Company have bought the franchise and works of the Augusta Gas-Light Company and will rebuild the works with new holder, etc. J. W. Averill is Manager.

BRIDGES.

BRIDGES.—The Commissioners of Montgomery County, Pa., are asking for bids for constructing the masonry of two bridges. They will receive proposals at Norristown until October 15.

TOLEDO, O.—At the last meeting of the City Council the following resolution was introduced and referred: *Resolved*, By the Common Council of Toledo, that the civil engineer be and is hereby directed to prepare suitable plans and specifications for the construction of a pile trestle bridge over Swan Creek at Hawley Street.

BRIDGE.—The Commissioners of Wood and Lucas Counties, O., will receive bids up to October 31, for labor and materials necessary for the erection of the superstructure of a bridge over the Maumee River, on the site of the present bridge at Waterville, Lucas County, O. The said bridge is to consist of five spans of 168½ feet each, and is to have a roadway 18 feet wide. Bidders are required to furnish their own plans and specifications, both for a combination and an iron bridge. Charles A. Vordtriede, Auditor Lucas County, Toledo, O.

WALTHAM, MASS., City Aldermen have adopted plans and report on a stone bridge over Charles River, placing the cost at \$30,875. M. M. Tidd, of Boston, is the engineer.

SAN PEDRO, CAL.—A \$300,000 dock or pier will be built here. Address C. Webb Howard, of San Francisco.

ST. PAUL, MINN.—Contracts for constructing the Marshall Avenue Bridge over the Mississippi River have been let as follows: For the substructure, to P. P. O'Halloran, to use Kettle River stone, \$33,136.96; for the superstructure, to the Canton Wrought-Iron Bridge Co., of Canton, O., for \$109,100.

WILLOWDALE, ONT.—Bids will be received to the 10th of October for building a steel trestle viaduct; also tenders for the masonry, abutments and piers for the same, on the creek and ravine near Toronto City Reservoir, on lot 16, con. 2 from Bay, Township of York. Address Peter S. Gibson, York Tp. Engineer.

GENEVA, N. Y.—Address George W. Bilsborrow, of the Town Board, in reference to two bridges, which it is proposed to build.

COLUMBUS, NEB.—A \$50,000 bridge will be built over Loup River. Address the City Clerk for further particulars.

BRIDGE.—See our Proposals for a reference to a bridge on the Pennsylvania Railroad.

BRIDGE.—In our Proposals will be found a reference to a bridge over Paddy's Run, Ohio.

ROME, N. Y.—The Highway Committee ask bids for constructing an iron bridge over Wood Creek.

WASHINGTON, D. C.—The Mount Vernon Bridge Co. has the contract for the manufacture and erection of the aqueduct bridge over the Potomac.

MONTGOMERY, N. Y.—The County Commissioners will build a bridge at Montgomery, N. Y.; cost, \$13,000.

ATLANTA, GEO.—A bridge will be built by the Central and East Tennessee Railway Co., at Atlanta. E. B. Thomas, Washington, D. C., General Manager.

POTTSVILLE, PA.—It is proposed to build a bridge at Washington Street.

ROME, GEO.—The Commissioners of Roads and Revenue have awarded the contract for the new iron bridge over the Etowah River on Bridge Street. The bridge will have a draw, and will cost about \$15,000.

STREET WORK AND PAVING.

MILWAUKEE.—Twelfth Street from Wells to Cedar Street, curbing, grading, etc.; Twelfth Street from Grand Avenue to Wells Street, stone curbing; Eighth Street from Locust Street to Burleigh Street, grading, graveling, curbing, planing, and paving; First Street from North Avenue to Lee Street, sidewalks to be planed; Conway Street from Kinnickinnic Avenue to Logan Avenue, grading, graveling, planing, and paving.

MOBILE, ALA.—It has been decided to do much granite street paving. Address the City Clerk at once.

CINCINNATI, O.—The contract for work on improving Crawfish Creek Road has been given by the Board of Public Affairs to Henry McErlane, at \$42,006.50.

TOLEDO, O.—The contract for paving Frazier Street has been awarded to Thomas McKenney, at \$14,695.10.

OAKLAND, CAL.—Grading, curbing, and macadamizing are ordered on Twenty-third Avenue. A. C. Henry, Clerk of Council, may be addressed.

NORRISTOWN, PA.—The Board of Trade urges the Council to pave certain streets. Address George N. Rogers.

NORFOLK, VA.—\$45,000 has been appropriated to immediate work on the paving of Granby and Holt Streets. Address the City Clerk.

CINCINNATI, O.—Grading and paving will be done on Grand and on Gleney Avenue. Address Fred. Raine, Auditor, until October 22.

LANCASTER, PA.—The Harrisburg Car Manufacturing Company has been awarded the contract at their bid for a stone-crusher for the Street Committee of Councils.

EAST ST. LOUIS.—Bids for granite paving and grading on Front Street were opened by City Council October 1, as follows: Allen & Vieths, \$46 per square for granite paving, \$2 per lineal foot for granite curbing, 80 cents per lineal foot for limestone curbing, and 55 cents per cubic yard for grading; Eyermann & Schmalz, \$49.50 per square for granite paving, \$1.60 per foot for granite curbing, \$1 per foot for limestone curbing, and 50 cents per cubic yard for grading. Niemes & Reimann, \$47.60 per square for granite paving, \$1.40 per foot for granite curbing, 80 cents per foot for limestone curbing, and \$1.25 per cubic yard for grading. This would make the total of each bidder for the work as follows: Allen & Vieths, \$104,279.60; Eyermann & Schmalz, \$111,955, and Niemes & Reimann, \$115,862. The bids were referred to a committee of five to examine and report.

EAST ST. LOUIS, ILL.—The contract for paving Front Street with granite has been given to Allen & Vieths, of St. Louis.

STEAM-HEATING, BUILDINGS, ETC.

TUSKALOOSA, ALA.—The Building Committee of the University of Alabama, of which Hon. W. G. Clarke, of Mobile, is Chairman, has awarded the following contracts: To the Union Iron Works Company, of Chattanooga, Tenn., for a complete system of water-works; to C. M. Robush, of Meridian, Miss., for two 8-room dwelling houses for professors; to F. Hubbell & Co., of Tuscaloosa, for a complete chemical laboratory 110 feet long and 70 feet wide.

AUGUSTA, GEO.—The City Council on October 3 accepted plans for a wharf and warehouse for the use of the new steamboat company, as prepared by the Council Committee. Mayor May was instructed to advertise for bids.

OAKES, DICKEY COUNTY, DAK.—A syndicate with a capital of \$100,000 has been formed to make improvements here.

ST. PAUL.—J. R. McMurran, P. T. Dwyer, and A. G. Postlethwait are interested in a new apartment house, 100x150, eight stories, to cost about \$250,000. Plans being perfected.

LOS ANGELES, CAL.—The supervisors let the contract for building the court house to O. E. Brady, of San Francisco, at \$375,000. Stone, brick and terra-cotta will be used.

TORONTO, ONT.—Plans for the court house are nearly ready for bids. Address Alderman Jones.

TOLEDO, O.—The Toledo Natural Gas Company has made a proposition to the City Council to heat the court house and jail with natural gas, at \$1,100 per annum.

PROVO, CAL.—The contract for the steel and iron work of the jail, to be built here, has been given to the Pauly Jail Building and Manufacturing Company of St. Louis.

CINCINNATI, O.—The Exposition Commissioners have refused bids on the building, and requested Architect Siter to modify plans so as to reduce cost to \$150,000.

RAILROADS, CANALS, ETC.

CAPE May, N. J.—The Electric-Railway Company will receive a franchise permitting the laying of tracks, etc.

BROCKTON, MASS.—S. G. Grover is president of the new street railway company, which will build a road on the East Side.

HELENA, ARK.—The city voted October 1 to raise by tax \$50,000 for levees. Work will be begun very soon. J. K. Klooster, U. S. Surveyor, may be addressed.

NEW YORK CITY.—The plans for the improvement of the bulkhead along the Harlem River from One Hundred and Fifty-ninth Street, under the cliff, have been approved by the Dock Department.

LOS ANGELES, CAL.—The Pomona Heights Railroad Company has been incorporated. It proposes to build a railroad from the Southern Pacific Railroad depot in Pomona to Pomona Heights addition. The directors are: H. A. Palmer, Frank Stevenson, R. S. Bassett, T. D. Holladay, and C. D. Ambrose. Capital stock, \$12,000; amount subscribed, \$11,500.

PITTSBURG, PA.—The Marshall Foundry Construction Company, of this city, have been awarded the contract for the iron roof of the Custom House at Richmond, Va., at \$8,360.21.

LOUISVILLE, KY.—Bids for furnishing stone for constructing a lock on the Wabash River, near Mt. Carmel, Ill., were opened October 1 by Major Amos Stickney, U. S. Engineers. Delivered on top of bank at site of lock:

(1) J. N. Hoag, Jr., Cincinnati, O., special stone, \$21; cut stone, dressed face, \$15; cut stone, quarry face, \$13; squared stone and backing, \$11.

(2) Salem Stone and Lime Co., Louisville, Ky.

(3) Edward Crumbo and Joseph Melcher, New Albany, Ind., \$25.10; \$16.90; \$14.60; \$11.90.

(4) Charles E. Rees, Cincinnati, O., \$20.87; \$15.87; \$12.87; \$8.87.

Delivered at railroad switch near the river at Mt. Carmel, Ill.: (1) \$19, \$13, \$11, \$9.

(2) \$20.15, \$17.65, \$16.65, \$11.40.

(3) \$22.60, \$14.40, \$12.10, \$9.40.

(4) \$19.12, \$14.12, \$11.12, \$7.12.

Building Intelligence.

We solicit from each and every one of our readers information relating to projected buildings in their locality, and should be glad to receive newspaper clippings and other items of interest.

THE KOUTS CAR-STOVE CREMATION.

THE mortality attending the railroad collision this week on the Chicago and Atlantic Railroad near Kouts, Indiana, in which some 12 people lost their lives, was mainly due to two causes: First, the car-stove and the method of lighting; and secondly, the flimsy construction of some of the cars that were crushed to kindling wood between their heavier neighbors, which were comparatively uninjured. If this continued cremation must go on for another winter, it is fortunate that so early in the season the public should have another warning that will direct their attention to the inaction of the railway authorities, who, with very few exceptions, so far as we are informed, have done nothing yet to meet the just demands of the public and obey the laws enacted in several States looking to the removal of the car-stove and the introduction of heat from an outside source. About eight months have elapsed since legislation required companies in certain States to abandon the present dangerous method of heating and lighting cars. A few companies have striven honestly to introduce methods which are not monopolized by any one patentee, but which are available and within the means of any company which is willing to pay a reasonable price for them, subject only to such embarrassments as are involved in any important change. We regret to say, however, that there is too much evidence that railway companies are unwilling to incur the expense of perfecting such details as only actual use will demonstrate to be desirable, preferring to wait for other companies more public-spirited to make these experiments, and apparently indicating in the meantime a disposition, if the car-stove is abolished, to give their passengers the alternative of being frozen.

Buddensieck was sent to State's Prison for having buildings put up under his direction which were so constructed that they fell down and killed somebody. In view of the state of the art in the matter of heating at this day, and the ability to heat cars from an outside source, there is no reason why the directors of our railroad companies should not be in a like manner punished if any lives are lost another year on the cars of their roads by reason of fire resulting from the present car-stove.

In a subsequent issue we hope to indicate what has been done and by what roads. Those who have been remiss in meeting a just public demand that they are entirely capable of fulfilling, may yet succeed in arousing public indignation to such a pitch that the next law enacted will make it homicide for the officers and directors of any road on which such casualties occur when it is proven that they have failed to provide their roads with such safeguards as every expert now knows is available.

STARVATION DROPSY.

It is not often within the United States that the effects of slow starvation upon a number of persons can be observed, but an opportunity of seeing this has recently been afforded by the parish prison of New Orleans, and the report of the investigation made of this place by Dr. W. H. Watkins, a sanitary inspector of the State Board of Health, reveals a condition of things which is very remarkable as occurring in a civilized country in time of peace. Attention was attracted to this prison by the occurrence of a number of

cases of acute dropsical swelling of the legs, arms, face, and body among the 300 prisoners confined in it. From Dr. Watkins' report it appears that each prisoner is allowed a piece of bread and a pint of tea early in the morning, and one meal consisting of soup, the beef cooked in the soup, and bread. The beef is furnished by contract at 5½ cents per pound, and it has several times been condemned by the resident surgeon. Dr. Watkins concludes that the disease is due to confinement, with insufficient and unwholesome food, and that the remedy is to furnish a more liberal diet of better meat and fresh vegetables. It might be supposed that some one was to blame for such a condition of things, but the report gives no hint on this point.

HOLBROOK HALL.

THE threatened disaster at Holbrook Hall, illustrated and described in another column, affords a very valuable and, we fear, much-needed lesson on the danger of excluding air from structural timbers, especially if not perfectly seasoned. Whether hemlock, the timber at fault in this instance, is more liable than other wood to decay under such circumstances, it is perhaps too soon to say, though the better experience with spruce would seem to indicate the superiority of the latter.

FORESTRY CULTIVATION.

It is with a feeling of lively satisfaction we note the fact that our Government is at last awakening to the necessity of a positive and energetic control of the forests of the country. The loss of the wood, which has been so ruthlessly cleared away, is the least of the evils. The scarred and barren mountain-sides, the increase of devastating freshets, the destruction of many thousands of acres of alluvial lands along our water-courses, and severe local changes in climate, are all evils flowing from this same source, and the lands thus devastated are absolutely irreplaceable in their former adaptability to the uses of man.

The woods may be restored after fifty to one hundred years where the soil remains, but the leaf-mold, and soil, which have been of many centuries' growth, are gone from many a mountain or hill, where formerly it supported and was kept in place by a beautiful forest.

So complete has been the destruction of trees along some of the cañons and passes in the Rocky Mountains for example, that a traveler would think the region treeless, were it not for stumps which yet remain. The effect of this is seen in an increasing deficiency of water in the streams during summer, so that the question of water-supply to the rapidly-growing towns in the region is a serious one. Nature's reservoirs—the sponge of the leaves, and mosses, and the rootlets of the trees—are destroyed, and it is now proposed to establish great artificial reservoirs, at enormous expense, to make up for the loss.

About a year ago the Assistant Secretary of State sent a circular to all consular officers asking them to obtain information upon all questions bearing on forest planting and culture, forest control, revenues, timber-supply, laws and regulations, etc. The reports received are now published in a pamphlet which is full of interesting matter.

Taking, for example, "Austria-Hungary," the laws are now so rigid that if enforced not a tree

can be cut even by a private owner "except in accordance with certain rules and restrictions."

The total number of forestry officers of all grades is 31,286, and each one must be specially educated for the position he holds, from the "chief forest counsellors" (*oberforstrathe*) to the lowest forest ward, with a salary of a little over \$100 per year. The profits of forest culture have largely increased during the last fifty years.

There are three grades of schools—university, middle, and elementary. In all of them a study of the causes of decay and destruction are important elements in the courses pursued. It cannot be questioned that with the destruction of insectivorous birds which is constantly going on there is increasing danger to the forests.

To show that we have not written too strongly respecting the fearful consequences of the indiscriminate destruction of great areas of woodland, we quote a passage from this report:

The causes of the destruction of forests have been the same in the Old World as in the New.

The greed of men, the desire of speedy gain without reference to consequences, the want of judgment and knowledge as to cause and effect in the courses of nature and its developments, have razed and shorn the forests along the spurs of the Alps and the shores of the Mediterranean with the same merciless energy which has been displayed in this direction along the shores of American rivers and on the slopes of American mountains.

A great area of the shore provinces of this Empire is now almost an arid desert. There is little timber in Dalmatia and Istria and in the territory near Trieste.

The dearth of timber and wooded slopes is so pronounced that the region has been denominated by a particular name "The Karst," which in its common acceptation is almost synonymous with "Sahara."

There was a time, though not within the memory of men now living, when all this region was covered with a dense oak forest.

Already in the year 452 before Christ these woods furnished the material for Roman castles, houses, and ships.

Venice, while in her pride and glory as queen of the seas, also drew her supply for ship-building and pile foundations from this source, and what was left was purchased and chopped down by the merchants of Holland and England.

When the timber was all cut down and nothing left but the roots there was still hope that a new forest would have grown up out of the bare ground during the course of centuries, but then the native inhabitants stepped in and took possession and by pasturing their sheep and goats upon the treeless plains and hillsides made all growth from the roots impossible, and they even dug up the roots for firewood, and thus made a very clean and thorough job of this barbarous devastation.

The result in a climatic direction has, as a matter of course, been highly disastrous. The same region which had been famous for its mild and temperate climate has become changeable and unreliable, landslides and avalanches have come and gone their unobstructed way, the mountain creeks have become dry, and the whole face of the country has been changed from a rich, fruitful, and salubrious climate to an arid, sterile plain, interspersed with stony and parched hillsides, populated by meagre sheep and goats and their equally meagre owners.

Austria is now trying to reclaim these wastes by tree-planting but the work is slow and expensive.

One of the forest laws makes it the duty of the owners of forest land to report insect ravages, in case they cannot control them, under heavy penalty for not so doing.

The Consul at Marseilles is equally positive as to the great loss South-eastern France has suffered through forest destruction. After giving the process causing the disastrous result, he states that about one-fourth of the whole region has been rendered totally unfit for cultivation. The process of reclamation has in 19 years cost the State nearly \$10,000,000, and 250,000 acres of land have been reclaimed.

The laws in France carefully regulate the felling of trees on slopes and points where the land, if denuded, is subject to wash by rains.

Much has been done to reclaim the sand-dunes by "first building palisades parallel to the sea

and then sowing the dunes with the maritime pine mixed with the seed of the furze and brush-broom." The forests thus raised have become sources of wealth, and the dunes made safe against encroachments from the sea.

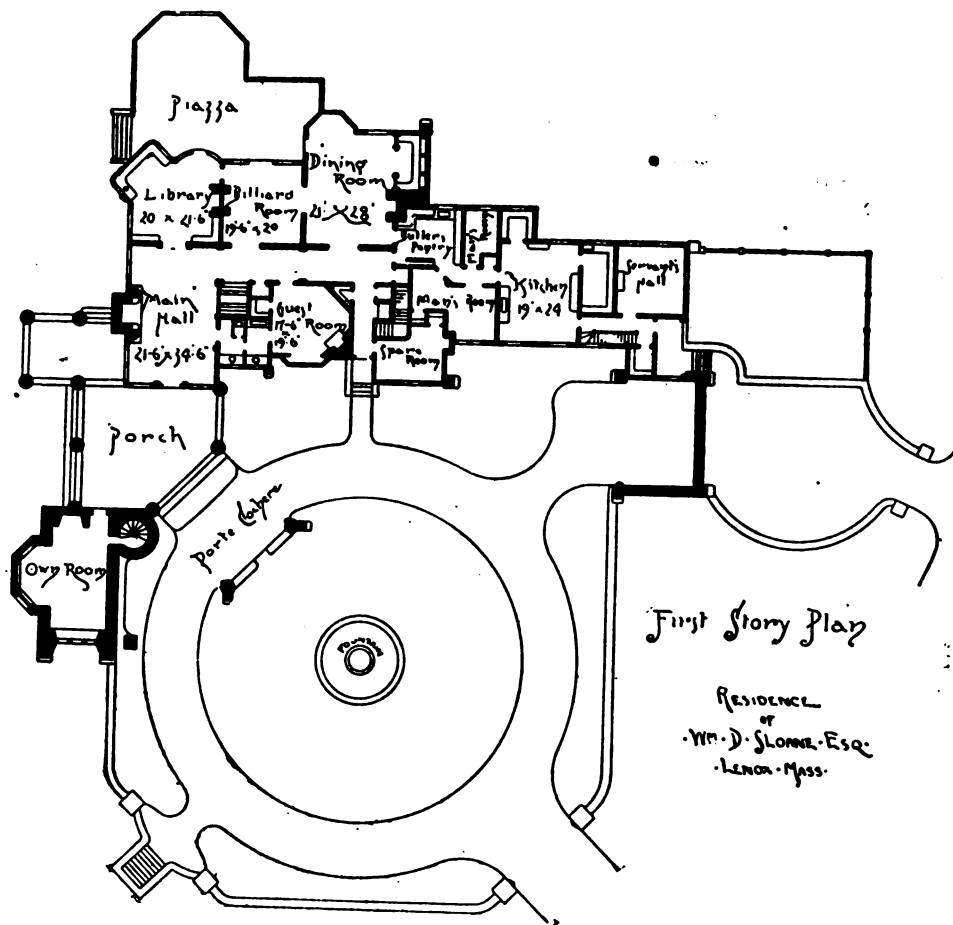

One of the interesting matters in the report is a description of the method taken to overcome an outbreak of insects, the common bark-beetle, in 1873-4. After an extensive series of windfalls caused by a violent storm the insects bred in great numbers in the fallen branches. One of the means employed was to use "decoy trees," which were felled and placed in sunny spots to catch the swarms when about to lay their eggs. The bark

OUR ARCHITECTURAL ILLUSTRATIONS.

RESIDENCE OF W. D. SLOANE, ESQ.

THE country residence of W. D. Sloane, Esq., at Lenox, Mass. The foundations, piers, etc., are of white marble from the local quarries; stained shingles for walls and roof. Interior: dining-room, quartered oak; library, cherry; elsewhere pine, painted. The marble used was the cheapest good local stone and was used for that reason rather than for show. The architects were Peabody & Stearns, of Boston.

was then stripped off, thus destroying the larvæ. The volume is full of interesting matter, but we can do no more than indicate its character and call attention of our readers to it.

THE VALUE OF HEALTH BOARDS.

(From Milwaukee Evening Wisconsin.)

TWENTY years ago the arrival of a cholera-infected ship like the one now in quarantine in lower New York Bay would have created a panic in the metropolis and aroused great forebodings throughout the country.

Now, the arrival of the death-laden vessel is noted and discussed by the newspapers as any other important piece of news might be, but there is no scare in New York, no getting away or staying away from the city, and no unusual anxiety anywhere.

The explanation of the differing deportment of the people then and now is found in the fact that the present Health Department of New York is so admirably organized and possessed of such proved efficiency in stamping out contagion, that it is confidently relied upon to prevent the dread disease from landing.

All that money and professional skill can secure and suggest are at the service of the New York health authorities. And so prompt and efficient has been their action that the Government at Washington has been notified by Government officials that there is no need of interference; the New York board is abundantly competent to do all that is required.

That Health Department probably costs New York a few score thousand dollars per year. Yet, because it is so efficient that the people have absolute confidence in it, there has been saved to New York alone within the last week, hundreds of thousands of dollars which would have been lost had even a partial panic possessed the people and so interrupted and injured trade.

What is thus true of New York is equally true of Milwaukee and Wisconsin. Quite aside from all considerations of comfort and happiness and humanity, the actual commercial value of wise appropriations for the efficient maintenance of our city and State health departments is beyond calculation.

PAVEMENTS FROM BLAST-FURNACE SLAG.

IN the Hanover district of Germany the blast-furnaces make a specialty of a road-metalling material called slag-stone. For its preparation the slag as tapped from the furnace is run into a bottomless cast-iron mold which is tapering to the top and stands on an iron truck. After the slag has cooled enough to have an outer shell sufficiently strong to support the melted mass inside the mold is lifted off and placed on another truck ready for use, while the loaded truck is run off to the dump-heap, where the truncated cone is pierced and the slag run onto the ground and covered with cinders and ashes and allowed to cool very slowly. This makes the slag much tougher than when allowed to cool in the open air, and it is said to wear very well when broken properly and placed on roads.

The ordinary brittle slag makes a very good foundation for a road, particularly on clay and wet soils, as by rolling, the top pieces form a powder that fills the interstices between the lower fragments so thoroughly that neither clay nor mud can work up through the layer, and on this the more durable wearing layers can be placed. It was found impossible to form any roads on the soft clay surface of the Centennial Fair Grounds at Philadelphia, until their beds had been prepared by a layer of well-rolled furnace-slag, after which they stood very heavy teaming without underdraining; the bonding of the fragments of slag with the thorough filling of the interstices preventing any mud from working through the first or lower layer thus keeping the road from breaking up.

1000

HISTORY OF THE DEVELOPMENT OF THE ART OF BRIDGE CONSTRUCTION.

BY PROF. W. P. TROWBRIDGE.

HAVING delivered an address before the New York Academy of Sciences on the "History of the Development of the Art of Bridge Construction," I have, at the request of the Editor of THE ENGINEERING & BUILDING RECORD, prepared from my notes the matter for publication in that journal, he having had made, from photographs in my possession, the drawings used to illustrate the article. No attempt was made to describe or demonstrate details of construction, but rather to trace the development of an art which has been, in all ages, to a certain extent, not only a sort of index or gauge of intellectual advancement

the arts are fostered, the bridge, in beauty of design and workmanship, is often the most significant expression, not only of the skill and genius of a people, but of their refinement and taste.

It is unfortunate in this latter respect that the necessities of railway traffic in modern times have caused the introduction of forms and modes of construction in iron, scattered everywhere throughout civilized countries, which mar the most delightful landscapes, and which contain no lines of grace perceptible to any one, except the engineer who may claim to find beauty in every structure which fulfills its objects. He only knows how much of intellectual labor the uncouth skeletons which carry our railway trains safely across the widest chasms have cost in the

which are now met with at every turn, and which are constantly being multiplied, simple architectural adjuncts to relieve their uncouth appearances. In one instance, at least, this has been done in this country with marked effect, though the conditions under which the structure was built were certainly unusually favorable in this respect. I allude to the Girard Avenue bridge in Philadelphia, designed and built by the Phoenix Bridge Company, a wrought-iron bridge, which has called forth from many a traveler from foreign lands expressions of delight on account of the architectural elegance of its design. (See cut.)

The history of the development of the art of bridge construction is marked, to a certain extent, by periods or eras coincident either with the introduction of new materials in the arts, or with the necessities which have arisen for compassing greater spans under conditions of heavier traffic. The suspension bridge, of very ancient origin, has held its place, though to a limited extent, until our own time, when its place is likely to be usurped, to a great degree, by the cantilever. Built in primitive times, with cables of organic material, the introduction of wrought iron and of iron wire furnished facilities of construction and elements of durability and strength which the older suspension bridges did not possess, and the great bridge between this city and Brooklyn may be regarded as the culmination of this system, and perhaps the most remarkable example which the world is destined to see; there being inherent defects of the system, which render it inapplicable to rapidly moving heavy loads, which will always be a sort of bar to its general use.

The reverse of the suspension bridge, the arch, of all systems has held the most universal sway until the long spans met with in the routes of railway communication, and the difficulties of establishing numerous piers in swift currents and on treacherous foundations brought about, first, the long-span timber bridge, and subsequently, the modern structures in wrought iron, which have become so common in our times. The history of the arch in bridge construction extends from a period farther back than the beginning of the Christian era to the present day; but the days when great engineers like Perronet, Nimmo, Telford, Rennie, and others could acquire fame by building chaste and beautiful arch bridges of stone masonry seem, unfortunately, to have passed.

One of the largest and most picturesque structures of this kind in the world, unsurpassed in many respects by the most famous arches of history, constitutes a part of the Potomac Aqueduct, near the city of Washington. This magnificent structure, called the Cabin John Bridge (see cut), erected by General M. C. Meigs, of the U. S. Army, will probably remain the most conspicuous memo-

THE GIRARD AVENUE BRIDGE
PHILADELPHIA, PENN.

and material progress, but also of wealth, taste, and refinement.

It is sometimes interesting and instructive to go back to the earliest times and follow up historical records and examples connected with any art, if for no other purpose than to compare our modern works with those of older date, even though we find little to be copied or reproduced of all that has gone before.

In works of engineering generally, unlike those connected with the fine arts, there is little to be learned from the ancients. We are surrounded on all sides by structures of a purely engineering character, which could only have been devised and executed in modern times, and for which antique models do not exist. There are certain elements, however, of these structures which belong to all ages, since they are but the practical applications of simple mechanical laws in which boldness of conception and design, simplicity and taste in construction, and perfect adaptability to their uses and objects, exhibit the intellectual condition of the people by whom such structures have been erected.

It may be said that properly constructed lines of land travel are both causes and effects of civilization. The common road and the railway, pushing out beyond the boundaries of populous districts or penetrating uninhabited wildernesses, are sure to be followed by an advancing tide of emigration, while the introduction and maintenance of thoroughfares more complete and permanent in their construction than was at first practicable is an indication of increasing thrift, culture, and refinement on the part of the people.

The famous engineer, Telford, who constructed many hundred miles of good turnpike roads in England and Scotland under special acts of Parliament, expressed the opinion or belief that these roads had advanced the communities of the districts through which they passed one hundred years in civilization.

The construction of a line of land travel involves, of course, numerous bridges, rude and cheap in primitive times, but exhibiting elements of a more permanent character and more pleasing architectural features as a country advances in wealth and education. There are few architectural structures which more truly indicate intellectual cultivation and general prosperity than the bridges found along the lines of intercommunication.

It is certainly true in our own day that a district in which streams are crossed only by fording is either sparsely populated, or else occupied by ignorant, unthrifty, and improvident communities. The energy, the talent, the means of surmounting material obstacles, are in such cases wholly or partially wanting, while, on the other hand, where wealth is accumulated and science and

efforts that have been required to design and adapt them to their uses.

An English writer on the subject of bridges in discussing, forty years ago, the designs of American timber bridges, although compelled to give them the pre-eminence, applied to them the remarkable criticism (because they were boxed in or covered on the sides and top to preserve them from decay), that they "looked like coffins for sea-serpents."

If this curious criticism be in any way applicable, it might be said now that the coffin has been removed and the skeleton, transmuted into iron, exposed fully to view.

It would appear to be not only difficult, but, in the eyes of many, a violation of constructive art to attempt to give the same pleasing appearances to most modern systems

of iron bridges that are easily and naturally embodied in bridges of stone; and although the present is the age of iron, yet it is to be hoped that the stone bridge, once the pride of the great engineers of history, may not be given up and forgotten, but that it may be reintroduced, whenever circumstance may allow, in order that it may again add beauty to our landscapes, even in rural districts and outside of the limits of ornamented parks and pleasure-grounds, to which it has in modern times been mostly confined.

It should not, however, I think, be considered impossible to add to the skeleton structures in wrought iron,

rial in this country of a system which, for highways and railways, is gradually being replaced by iron.

Cast-iron arch bridges were first introduced a little over one hundred years ago in England, and for a time met with marked public favor. The facility with which cast iron lends itself to the introduction of minor decorations in forms and moldings enabled bridge architects to present a great variety of pleasing designs, and numerous bridges were constructed about the beginning of this century which attracted much attention. It has been claimed that Thomas Paine, whose name has been preserved in history only through his atheistical writings and doctrines,

was the inventor of the cast-iron arch bridge. This claim is, however, not well founded, inasmuch as this kind of bridge was already in use in England before Paine sailed from America with the object of carrying his plans abroad, where he thought they might be favorably considered.

The cast-iron bridge had, however, but a brief historical record. The want of sufficient elasticity, the imperfection of castings, and the liability to rupture under sudden strains or blows has caused cast iron to be thrown out of the catalogue of available materials for the principal elements of bridges of any considerable importance.

SCHAFFHAUSEN TIMBER BRIDGE OVER THE RHINE

Of timber bridges it may also be said that they have had their day and have fulfilled their temporary uses. When railways were first introduced about the end of the first quarter of the present century, the necessity of providing bridges along their routes of longer span and cheaper construction than could be furnished in stone led to a more critical study in the use of timber for bridges than had ever before been bestowed on the subject. Previous to this, however, many noted bridges had been built, which were masterpieces of work in timber, and which have preserved to history a few names which will always be remembered in connection with the noble art of carpentry; an art now, for various reasons, in its decline. Among these names that of Ulrich Gruebenmann, who built the famous bridge over the Rhine at Schaffhausen toward the end of the last century, and the name of Timothy Palmer, of Newburyport, Mass., will always be prominent. The timber highway bridges of the latter in this country were models of scientific, practical, and mechanical workmanship. The Schaffhausen bridge stood alone as a great work, in which the inherent principle of construction was the arch, combined with the elements of the common roof, but it brought into use no new principle, and had no elements which might cause it to be reproduced or copied.

Another name destined to a more substantial and enduring fame in connection with timber bridges is that of Ithiel Towne, for many years before his death an architect

people of New Haven who know its history is the chief object of interest in this particular spot. Few persons, however, are aware of the fact that the mechanical design of this bridge was the first departure from the principle of the arch and the suspension principle ever attempted; and that it is, although constructed entirely of timber, without a nail or a spike except those used in the board covering, the prototype of nearly all modern constructions in iron which have of late years become so numerous, and which are classified as braced girders. This bridge was devised and erected by Ithiel Towne, about the year 1823, for the

New Haven and Hartford Turnpike Company, across the Mill River. It is 100 feet long, fourteen feet wide, and twelve feet high, and is built on the principle of straight top and bottom chords, connected by diagonal bracing; a

PONT DU GARD BRIDGE - FRANCE

principle invented by Mr. Towne and never before introduced into bridge construction.

About the year 1840, Mr. Eli Whitney, of New Haven, who was then constructing the dam and reservoir on Mill River, which now supplies New Haven with water, removed this bridge bodily on skids from the point where

was the employment of an entirely new principle in bridge construction, which, by a mere change from timber to wrought iron and steel, has been followed ever since. Details have changed, the modifications giving rise to various types as they are known at the present day, but the fundamental principle has been almost universally adopted in all countries, and remains unaltered.

The tubular bridge, a later design, of which the famous Menai Bridge, erected by Stevenson and Fairbairn across the Menai Straits, is the most conspicuous example, has had no important development, skeleton structures being now universally preferred.

The latest advance in what some would prefer to call the "evolution" of the bridge, is the cantilever system. Though designs were made, and the system strongly urged upon the engineering profession of this country nearly twenty years ago, for spans exceeding the possible limits of the straight girder,* yet it was not until Mr. C. C. Schneider designed, and the Central Bridge-Works, of Buffalo, constructed, under his supervision, the Niagara Cantilever Bridge, that the merits of this system for very long spans became fully appreciated.

The system has spread with great rapidity since the Niagara Cantilever Bridge was completed, the Forth

TOWNE LATTICE BRIDGE

of New Haven, Conn. Two or three miles out from New Haven there is a covered bridge spanning a narrow part of Lake Whitney, which, in connection with the subject which we are discussing, has an interesting history. This bridge, a sketch of which, recently made by myself, is shown above under the name of the Towne Lattice Bridge, although presenting in itself no artistic feature, being entirely covered in, and being, in fact, the first of the bridges which on this account was sneered at by the eminent English writer referred to as looking like "a coffin for a sea-serpent," is nevertheless the central feature of a limited but charming little landscape, and to the

it was first erected to the place it now occupies, about half a mile distant—a difficult feat of engineering, but accomplished without removing or displacing a single timber of the bridge. The bridge is thus probably the oldest timber bridge of any considerable span in this or any other country, having fortunately escaped the fate of nearly all large timber bridges—destruction by fire.

The principal parts have never been renewed, and, thanks to the board covering, these parts are still sound and serviceable.

I have dwelt at some length on the history of this particular bridge, because the interesting feature of its construction

Bridge now being erected in Scotland on this principle and destined for railway traffic having the extraordinary span of seventeen hundred feet, a greater length than that of the New York Suspension Bridge.

A cursory glance at the development of the art of bridge construction thus reveals a series of interesting facts:

First—That masonry arch-bridges, from their simplicity, elegance, permanence, and strength, have in all ages been the most favored forms of construction for highways, and that the use of iron and steel has in no way changed this popular favor, except where the employment of these materials is either favorable to economy or to the introduction of larger spans. For railway-bridges, other considerations favor also the use of iron and steel over the use of stone.

Second—The introduction of cast-iron arches, though favorable to architectural elegance of design, has not resulted in any permanent useful developments.

Third—Timber bridges have in all ages been regarded as temporary structures which were to be replaced sooner or later by others more permanent in character.

Fourth—The springing up and immense development of the railway systems of the world within the last sixty years, and the concurrent progress made in the metallurgy of iron and steel, have given rise to entirely new problems in bridge building and to a new branch of the engineering profession.

Fifth—The demands of railway traffic for direct lines which must surmount every obstacle either by tunnels or bridges, the heavy weights transported, and the great speed of trains required, have diverted, for a time, public interest from the highway; formerly, in the time of the old stage-coach, the source of many peculiar delights to the traveler.

* Mr. C. C. Schneider, the designer of the Niagara Cantilever Bridge, asserted, at the time of the delivery of the address, that the design of the bridge over Blackwell's Island, here illustrated, was the first cantilever design proposed for this bridge by Professor Trowbridge nearly twenty years ago, and that this design was, to his knowledge, the first one in which the cantilever principle was applied to a long span and properly taken advantage of for the purpose of facilitating erection without obstructing navigation.—Ed.

We are now rattled over bridges and whirled through tunnels at a speed which precludes more than an unsatisfactory glimpse of the scenery which seems to flit by us; comfort, safety, and speed fill the measure of our expectations. But the change has caused our highways to be neglected, and even in the great thoroughfares which lead out from our cities and towns the iron bridge seems to have driven out the more beautiful and durable structures in stone, which ought here, at least, to occupy their proper places. There is no internal improvement more imperatively demanded in this country at the present time than systematic reconstruction and maintenance of our highways.

Viewed as intellectual and mechanical achievements, however, the great bridges of modern times are to be classed with steamships, locomotives, and pumping-engines, which could not have been suggested a hundred

Another Roman bridge, 2,400 feet in length, near Lyons, in the south of France, was also erected by the Romans.

Among the later Roman arched bridges may be mentioned the Devil's Bridge over the Serchio, Italy, which is, in some respects, the most remarkable in the whole history of stone bridges, being only twelve feet wide between the parapets, and spanning a stream in which the floods rise sometimes nearly to the crowns of the arches, and yet, while every other structure on the turbulent Serchio has been swept away, this bridge has withstood the floods of nearly nine centuries.

The bridge of Trezzo, built in 1380 by Bernabo, Visconti, Duke of Milan, consisted of a single arch of granite of 251 feet span, the largest stone arch probably ever erected. It was destroyed by Carmagnola 120 years after its erection.

The aqueduct bridge of Alcantara, near Lisbon, begun 1713, and finished in 1732, consists of thirty-five arches of various dimensions, the largest having a span of 108 feet.

The bridge of Neuilly, which crosses the Seine, built between the years 1768 and 1780 by the famous Perronet, is considered one of the most beautiful of existing bridges. It consists of five equal arches of 128 feet span each, each arch being composed of eleven arcs of circles

years ago by the most vivid imagination. They are triumphs of science rather than of art, and as such we should, perhaps, be content to look upon them; deriving our interest from cold, unimpassioned reflections upon the thought, the genius, and the skill which have produced them, rather than from any such pleasing emotions as

arches of 780 feet, and on these is supported a third tier 850 feet in length. This brings the structure up to the level of the aqueduct, which rests on the third tier of arches. This extraordinary structure is built of very large stones put together without cement and held together by iron clamps. The whole height is 190 feet above the river.

arise when we look upon some of the works of the same kind of the older bridge architects.

The most ancient bridges of which we have any precise knowledge were built by the Romans, all those of a permanent character having been arched masonry bridges. It is certain, however, that such bridges were built in China many centuries ago, but of their history little is definitely known.

Of the Roman bridges that erected by Trajan across the Danube is said to have been the most magnificent. It consisted of nineteen arches, each 170 feet span, the piers rising 120 feet above the foundations. The width of the bridge was 60 feet, and its total length 1,500 feet. This bridge was destroyed by the immediate successor of Trajan, Hadrian, for fear that it might afford an easy passage for the barbarians into the Empire. Some of the piers are still to be seen, however, near the town of Walke, Hungary.

The next considerable work of this kind built by the Romans is the Pont du Garde, which is still standing. (See cut.)

It served the double purpose of a highway bridge over the Gardon and an aqueduct for supplying with water the town of Nismes in the south of France. The bridge is a triple arcade, the lower tier of arches having a total length of 660 feet, and supporting a second tier of eleven

Another Roman bridge over the Tajo at Valenza, about 25 miles from Madrid, 679 feet in length, and consisting of only six arches, was built at the time of Trajan. It is now standing, but not used.

A single arch near the old town of Brionde, in France, having a span of 181 feet, and which is said to be still standing, is attributed to the Romans.

of different diameters, the resulting effect being a curve in appearance like an ellipse, but even more pleasing to the eye than an ellipse.

In England the oldest bridge remaining entire is the bridge of Croyland, in Lincolnshire. It was erected about the year 860.

The first bridge over the Thames was of wood, built in

the reign of Ethelred II., about the year 1000.

The Old London Bridge was begun in 1176, under Henry II., and finished in 1209. The length was 940 feet, the height 44 feet, and the width between the parapets 47 feet. It was hardly much more than a wall of stone thrown across the river, a few openings being left for the passage of the waters of the Thames, half the

water-way being taken up by the piers. It was extensively repaired and altered five hundred years after its erection, and in 1823, the obstruction which it offered to traffic on the river having become the subject of persistent and loud complaints, this bridge was removed and the New London Bridge erected in its place by Mr. John Rennie. The new bridge was placed near the site of the old bridge, and is formed of five semi-elliptical arches, the least of which is larger than any elliptical arch ever before erected.

The Westminster Bridge over the Thames was constructed by a Swiss Engineer, Mr. Labalye. It is 1,220

as well as magnificent in its proportions, erected by Mr. Roebling across the East River between New York and Brooklyn.

In timber bridges America has taken the lead of all other countries, the only structure in Europe comparable with the great timber bridges built in this country during the early part of this century being the Schaffhausen and Wittengen Bridges across the Rhine, built by Ulric Grubenmann. A stone bridge that had spanned the Rhine at Schaffhausen having fallen, a model of a wooden bridge to supply its place was presented by Grubenman, and

feet long, and consists of thirteen large and two small arches. It was opened to the public in 1750.

Blackfriars Bridge, also one of the London bridges, was built by Mr. R. Mylne, between the years 1760 and 1771. It is 999 feet long and consists of nine elliptical arches.

The Waterloo Bridge across the Thames nearly midway between the Westminster and the Blackfriars bridges is, perhaps, the most magnificent structure of its kind in Europe. It was built by Mr. Rennie, and is composed of nine elliptical arches, each having a span of 120 feet. Its length is 1,380 feet.

The first cast-iron arched bridge was built across the river Severn at Colebrookdale, England, by Mr. Darby, in 1779. Some years after Thomas Paine made preparations for erecting a similar bridge at the same place according to plans which he had prepared in this country, and caused his bridge to be erected for exhibition in a meadow near

accepted. This extraordinary work was completed in 1758. The length of each span was 364 feet. It was destroyed by the French in 1799.

Another famous bridge of timber, called the Colossus of Fairmount, was erected over the Schuylkill, at Philadelphia, by Luis Wernag, towards the close of the last century. It had the form of a very flat arch, having a span of 340 feet. Its slender, graceful appearance was much admired.

Fannie Kemble, in her journal, compared it to a "scarf rounded by the wind and flung across the river." It was destroyed by fire in 1838.

Timothy Palmer, of Newburyport, Mass., built several notable bridges, one of which crossed the Schuylkill at Philadelphia. The construction was a combination of king-posts and bracing with the arch. Another was built across the Piscataqua River about seven miles above Portsmouth. Both these bridges received extended notices in both American and foreign journals.

Colebrookdale, but having no funds to erect the bridge across the Severn, it was removed from the meadow and parts of it used for a bridge over the Wear in 1793.

Vauxhall and Southwark bridges over the Thames were of cast iron. The latter, built by Mr. Rennie, was composed of three cast-iron circular arches, the central arch having a span of 250 feet. Ten years were occupied in its construction.

Iron suspension bridges were constructed in Europe as early as 1615, but this class of bridges had already existed in Asia, Africa, and America at much older dates. The Spaniards found a suspension bridge in Peru, built by the fifth Inca, the cables, four in number, being composed of vegetable fibre, and the floor made of rushes. This bridge was systematically repaired every six months and remained standing and in use up to a very recent date.

Telford constructed a suspension bridge across the Menai Straits of 560 feet span, which at the time was regarded as a great achievement. All suspension bridges of the old world are, however, insignificant in comparison with the great bridge, beautiful in design and appearance,

Among the architects of notable timber bridges during the early part of the century appear the names of Burr, Towne, Long, and Howe—Long and Howe having followed Towne, and produced modifications of his truss to which their names have since become attached.

Towne's truss was such a remarkable and important improvement—the application, in fact, of a new mechanical principle in bridge building—that it was immediately extensively copied, the most important example being the bridge erected across the James River at Richmond, built by Mr. Moncure Robinson. The total length of this bridge was 2,900 feet. It was supported on eighteen granite piers at distances apart varying from 130 to 150 feet, the total cost being about \$100,000. Other bridges on the same principle were built, one across the Susquehanna 2,200 feet, with span of 220 feet; another at Nashua, N. H.; at Newburyport, Springfield, Northampton, Philadelphia, Trenton; one near New York, another near Troy, and many others in the Southern and Middle States.

These bridges have nearly all disappeared, wrought iron having taken the place of timber, while the principle of Towne is still preserved in new constructions.

Of wrought-iron bridges it is hardly necessary to refer at this time, since they belong to our own period, and are the work of engineers of our own day.

SOME DETAILS OF WATER-WORKS CONSTRUCTION.

BY WILLIAM R. BILLINGS, C. E.
Superintendent of Water-Works, Taunton, Mass.

NO. II.

(Continued from page 463.)

FIELD WORK.

It goes without saying to the readers of THE ENGINEERING AND BUILDING RECORD that the best preparation for any considerable amount of main-pipe laying is found in a careful survey of the proposed line, which shall take note of every feature which is likely to affect the work. Cross streets or roads, existing or proposed, brooks, bridges, drains, culverts, sewers, gas-pipes, and old water-mains, if there be any, should be indicated on plan and profile, and forethought given to schemes for avoiding and overcoming evident obstacles.

Let me warn the novice that, in spite of his most earnest forethought, obstacles that could hardly be foreseen even by one of experience will almost certainly arise, and he can at best only strive to reduce the number of the unexpected difficulties.

The need for laying pipes to line and grade is an imperative one on the main line from a reservoir in a gravity system; is almost as necessary with any main larger than ten or twelve inches, though perhaps less important in the smaller pipes through the streets of a town.

A town may build a respectable system of water-works with a wonderfully small amount of engineering, but money saved at the outset in this way is generally expended at a later date in correcting blunders and repairing defective work. The writer calls to mind at this moment an instance in which a defective length of pipe which was made a part of a submerged river-crossing has since caused an expenditure of not less than \$2,000 at different times for repairs; enough to have paid for a reasonable amount of engineering and thorough inspection.

Let us suppose that full surveys and drawings have been made: in what form, then, shall they be put, so as to be intelligible to the foreman in charge of the gang? If an assistant engineer is constantly on the trench, he may not need a full drawing; his own notes made at the office may be sufficient, but this arrangement is not always practicable. We give herewith Fig. 10, a sketch copied from blue prints used by Mr. R. P. Coggeshall in his work at New Bedford, Mass. These sheets are not large, 10x15 inches or less, and are given to the foreman a few days before the beginning of work, so that he may get the gates, hydrants, and specials on the ground in advance of the digging. The writer has followed essentially the same plan, but in his drawings no attempt is made to show the form of the special castings. Single or double lines, with the names of the castings and size of gates, the whole drawn to scale of forty feet to one inch, are used as shown in Fig. 11.

If a draughtsman is available the first method is certainly to be preferred, but if one must be his own engineer, superintendent, and draughtsman, as is often the case in small towns, the second method has its advantages.

These pipe plans represent the best practice, but if the earth could be thrown off some main-pipe systems, as the valet of Frederick the Great used to throw the bed-clothes off his master in the morning, the easy curves and special angles which the foregoing plans provide would not be found.

I once heard a man of wide experience in handling pipe say that he could lay cast-iron pipe in the crookedest town that was ever laid out on the cow-paths, if he had single branches and plenty of pipe. Such work is not to be commended, but it has been, and probably will be, done.

It would be outside the scope of these papers to describe methods which may be employed in locating a pipe-line and staking out the curves and angles according to railroad practice, but some beginner may be glad to receive some suggestions as to methods. When he is given a gang of men, a quantity of straight pipe, and told to lay a main on B Street from a given point to a branch on S Avenue, the location of the branch will be given with more or less accuracy, but at points all askew for B Street, and the street itself straggles along to a junction with the avenue in a tangential, uncertain sort of way that is more picturesque than satisfactory.

The first comforting fact is that we *can* swing around the sharpest curve which is likely to present itself by cutting the pipe into short pieces and making the joints as one-sided as we dare.

We must have a line of some kind—sash-cord or clothes-

line are first-rate for the purpose—so that we can fasten one end of it to a point in the ground nearly over the branch, say 18 inches to the right of it. Now let a man take the ball or coil of line and stretch it in the direction in which the branch points, as nearly as can be judged. Suppose the line is to swing to the right, let one laborer drive his pick into the ground close to the line, on the right of it, and 12 or 15 feet from the fastened end. Keep the line stretched, swing it to the right again, and have another pick driven into the ground 25 or 30 feet from the fastened end.

When a hundred feet or more of line have been stretched

In loose, gravelly and stony ground the temperature will frequently fall below 32° Fah. for a depth of 5 or 6 feet, and hydrant-branches and service-pipes have frozen under such conditions. In compact earth free from large stones, the ground is not frozen more than 3 or 4 feet, and under good sod the distance is even less than that. These figures will hold good, I think, as far north as the isothermal line of Portland, Me.

Any section of a main pipe-line which is sure of a good circulation may be laid at any convenient depth without regard to temperature, and examples may be cited of main pipes which cross bridges without any protection from

Time-keeping, if one wishes to know with exactness the cost of the whole or any portion of a season's work, is an important detail, and a convenient and well-designed time-book is almost indispensable to good results. A sample page from the time book in use by the writer will illustrate one method which has been well tried and is not found wanting:

FIG. 12.

With the aid of this book we have been able to tell with satisfactory exactness at the end of a season's work where every dollar of the pay-rolls has been expended.

For example, the page here given tells us that Jack Cade is number 49 in the gang; that he is paid \$2.25 per day; that on the first day of August he worked only during the forenoon, in the derrick-gang on Bay Street; on the second he made a full day in the same position; on the third

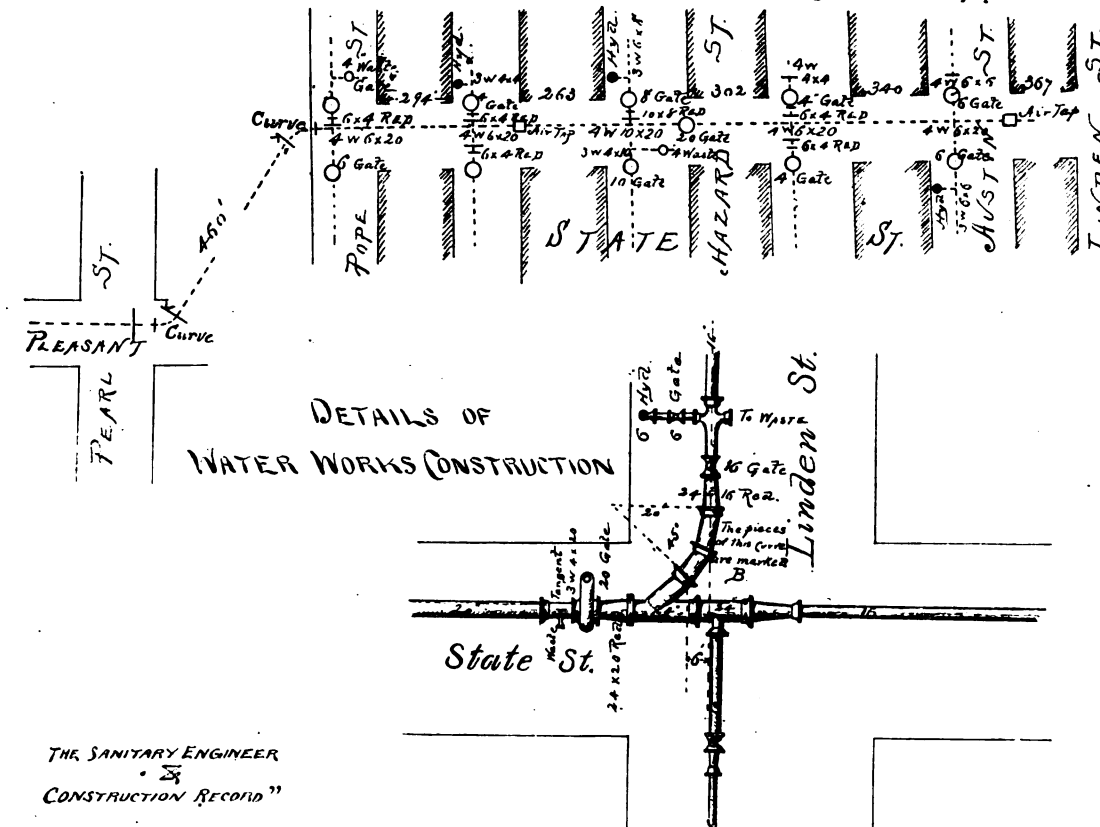

FIGURE 10.

in this way, set a half a dozen men to picking a rut along the left side of the line. Make them follow the line; don't let them walk backwards, and see that they all pick on the same side of the line; it is safe to say that half of them won't if you let them alone. The sections may be measured by laying down a shovel-length four times, or, if the digging is sandy, 15 feet is not too much.

The width of the trench may vary from 28 to 36 inches,

freezing except that afforded by the current of water constantly moving through them. Exact information upon this point is desirable.

There is a sort of unwritten law, in New England at least, that the axis of all pipes should be five feet below the surface.

If the amount of work on hand justifies the employment of not less than forty or fifty men, it will require the attach-

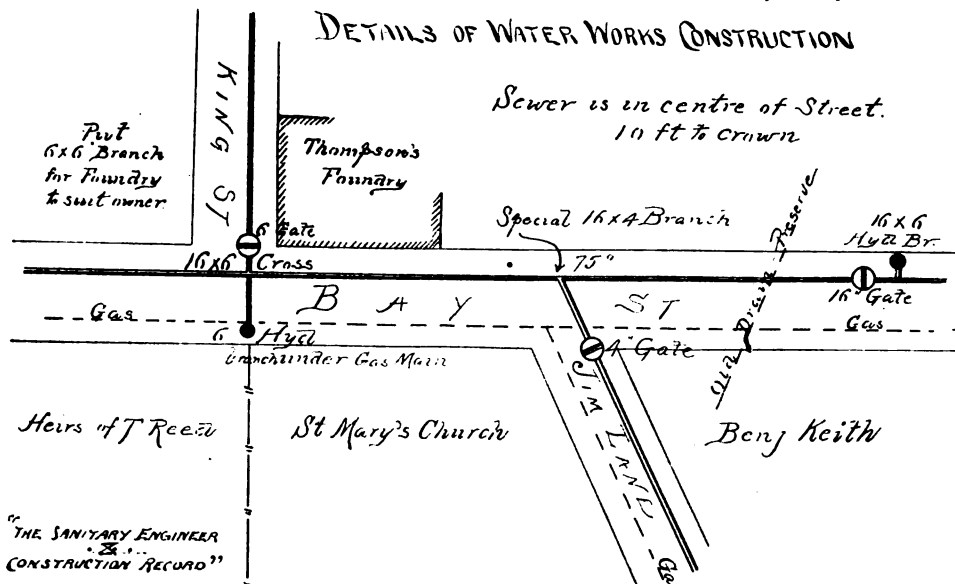

FIGURE 11.

depending on the size of the pipe, though if the soil is known in advance to be sandy, and likely to cave, it may be cheaper to start the trench four feet wide on top, and slope it towards the bottom, rather than to use bracing.

The depth to which pipe may or must be laid is controlled by more than one consideration.

In northern latitudes protection from frost is first to be thought of, and the amount of covering required for this depends upon the nature of the ground, the size of the pipe, and the quantity of water flowing during the hours of minimum flow.

tion of one capable man whose duty shall be those of a foreman of the trenching gang.

The right man in this position will have no lack of work. He can keep the time for the whole gang, lay out the trench in advance, see that the damage from the excavated dirt is reduced to a minimum, keep private driveways open, look after the bracing of the trench if this be found necessary, see that the trench is dug to the line and grade given, keep the unoccupied side of the road as free as possible, and finally pick out the fellows who are trying to shirk and get rid of them.

FIGURE 13.

he did not begin until the middle of the forenoon, finishing out the day. As pay-day comes once a week the space belonging to Sunday is utilized to put down the footing of total time for each week. On Tuesday, the seventh, Cade during the forenoon worked on Bay Street and on High Street after dinner, and Ck. shows that he was employed in calking joints. In Tim Daley's record B. H. stands for "bell-hole digging," B. F. for "back filling," Tr. for trenching, and C. S. P. (construction service-pipe) shows that Daley was taken from the main pipe gang on those days and sent to dig service-pipe trenches.

BUILDING RECORD

Street

In working through the streets of a town, especially in the portions occupied by well-kept estates, it is well to remember that a man with a newly-painted fence or a bit of smooth grass-plot is very unwilling to allow gravel or clay to be thrown against his fence or on to his lawn, even if the street be narrow and the workmen cramped for room. A few hemlock boards do not cost much and may save considerable growling, for if they are judiciously placed against the fence they will protect both it and the lawn. Under these conditions, however, there is some danger, if the dirt reach nearly to the top of the fence, of straining the structure and throwing it out of line. If this happens the fence must be straightened and the bill paid.

When tunneling is impracticable driveways and cross-streets may be kept in constant use by opening the trench half way across the space, leaving just driving room, and then digging on as usual. When the pipe-line is brought up to the undisturbed portion, the last two or three joints may be made without waiting for others, then enough of the trench immediately filled to furnish new driving room, and the undisturbed portion dug out by the derrick gang in quick time.

Bracing, if done to any considerable extent, is expensive work, but as it is not right and does not pay in Massachusetts to expose men to risk of injury, bracing the trench is sometimes not to be avoided.

If the tendency to cave is only slight and the trench is not more than five feet deep, sufficient support may be given by single planks running along just below the edge of the trench and held in place by short pieces of 4x4 joist, which are cut a little longer than the distance across the trench between the planks, and then driven in place with sledges.

In loose gravel or sand this sort of bracing amounts to little or nothing, for the stuff will run out from under the planks and finally tumble everything into the ditch.

Water-pipes are seldom laid to a depth which requires the thorough bracing and sheet-piling of deep sewer-work, but a simple sketch and a few words of explanation will make plain the vital points involved in the construction of ordinary sheet-piling. After excavating four feet in depth, a trench which must go four feet deeper, in quicksand, for example, may be braced as indicated in Fig. 13. Lay the 4x6 stringers B along the bottom of the trench and put a 10-foot plank between each end and the bank. Cut cross-braces C long enough to drive in hard, and then fix the top stringers T in the same manner; the next is simply driving plank to make the sheet-piling complete.

The one thing needful to make sheet-piling thoroughly effective is to keep the ends of the plank as much below the bottom of the trench as is possible, and to this end each plank should be driven frequently if only a little at a time. If the ends of the plank are cut this way—that is, chamfered and pointed—so as to help to throw them back against the bank and sideways against the plank last driven, better work can be done than with square-toed plank. If the amount of driving is considerable it will pay to protect the ends of the planks by a wrought-iron cap. Driving is to be done with wooden mauls, six inches or more in diameter and twelve inches long, bound with rings of wrought iron.

(TO BE CONTINUED.)

DR. E. W. BUCK, who is Health Officer and City Physician of Oakland, Cal., in his report for the year 1886, gives the number of deaths during the year as 583 and estimates the population at 46,000, giving a death-rate of 12.67 per 1,000. It is, of course, much more probable that the population has been overestimated, and that the true death-rate is at least 15 per 1,000, which, though low, is not an improbable rate for a new Western city like Oakland.

As Dr. Buck remarks, the large area of the city and the fact that most of the houses are isolated, together with the equable climate and good sewerage, explain in part the low death-rate. Probably, also, the comparatively large proportion of adults and the absence of a tenement-house population have much to do with the low death-rate. Reference is made to the usual troubles connected with dumping of garbage, and it is recommended to buy more land for the purpose. Probably the wisest course would be to construct a cremating establishment at once and prevent all danger of soil pollution.

The appended report of Mr. Snook, the sanitary and plumbing inspector, shows that the plumbing regulations are being enforced with good results.

DOMESTIC ENGINEERING, ETC., IN THE
EQUITABLE LIFE INSURANCE BUILD-
ING, NEW YORK CITY.

No. II.

(Continued from page 522.)

THE new Equitable Building, in this city, an illustrated description of the plumbing of which appeared in our last issue, is one of the finest commercial structures in the world. It was formally opened for business on May 1, 1887, but, as a matter of fact, there are yet many artisans employed in and about the building, some of whom may not be dispensed with for a year to come. When fully finished and equipped, it will contain, without much doubt, the greatest domestic engineering plant of this continent, or, presumably, any other. Money has not been spared in making it not only imposing in appearance, but, from the foundation up, it is notable for solidity and strength. It is fire-proof in so far as knowledge on the subject goes; it is believed that no fire started within the building could gain headway, and that the building would stand against a general conflagration outside. The best known modern appliances, in the judgment of the architect and engineer, for convenience and dispatch has been adopted.

The building occupies an entire block, with the exception of Nassau Street corners. It is bounded by Broadway, Cedar, Pine, and Nassau Streets respectively, it being one block north of Wall Street. The main corridor runs clear through the building—lengthwise—from Broadway to Nassau, and forms the main entrance from both streets. In addition, there are wide passageways leading from Pine and Cedar Streets, the meeting of which with the main corridor forms the shape of a cross, which, being covered and level with the street, makes it a convenient and much-used thoroughfare.

The frontage on Broadway is 167½ feet, on Cedar and Pine Streets 224 feet each, and on Nassau Street 46½ feet. The extreme depth of the building from Broadway to Nassau Street is 308 feet, the exact ground plan of which is shown in Fig. 1. The building is eight stories high. A central tower rises to a height of 172 feet from the ground. A central court, open to the sky above the first story, affords light and air to the inner rooms. The portion of this court intersected by the main corridor is covered by an arch of stained glass, on which there is much artistic display. The arcade thus formed is largely occupied at the sides by a variety of stores and offices of a public character, such as express, telegraph, messenger, telephone, etc., while a large part of the ground floor adjoining the arcade is used as a high-class public restaurant.

The building has a permanent and transient tenancy. Among the former are the "Mercantile Safe Deposit Company," whose offices, safes, and vaults occupy a large portion of the ground floor and cellar; the Mercantile Trust Company; the offices of the Equitable Life Assurance Society located on the second or "Equitable" floor, and the U. S. Signal Service Department, whose offices are in the tower. Certain portions of the building are fitted up expressly for tenants of a certain class—for example, banks, money, note, financial, and real estate brokers.

A special feature of the building is its Law Library, containing over 7,000 law volumes, also a daily supply of the latest law publications. It is reserved exclusively for the use of the tenants of the building. There are a number of alcoves, with tables, chairs, and writing material in this room, which is located on the fifth floor, adjoining the Law Club. On the ground floor the Mercantile Safe Deposit Company provides for tenants' use reading, smoking, writing, and coupon rooms, also a ladies' parlor.

Rooms in the building are also set aside for references, arbitrations, conferences, and general meetings; these are hired by the day for the purposes mentioned.

On the third, fourth, fifth, and sixth floors there are some sixty-eight to seventy rooms, all similarly arranged. On the seventh floor the arrangement of offices

materially from that on the other floors; every alternate room is larger than that adjoining, and the windows differ in size and shape; the smaller rooms contain closets valuable for permanent storage of articles, clothes, etc., while the windows of the large rooms have window seats and book-shelves on either side. The eighth and highest general floor contains a great number of small rooms, those fronting on Broadway being considered especially suitable, on account of the unobstructed light and high, clear position, for architects, engineers, etc.

The height of the eighth floor is 135 feet from the ground, while that of the tower is 178 feet, making the tower 43 feet above the eighth floor. Here is located the private retreat of the President of the Equitable Life Assurance Society. It is reached by an elevator erected on the ninth floor, which operates from the President's rooms on the second, or "Equitable," floor to this quiet retreat on the eleventh floor. The tower is occupied, also, by the U. S. Signal Service Department, the roof being given up to displaying the various signals for the benefit of the shipping in New York Bay and Harbor, and also for the surrounding country.

The building is heated by direct radiation, which will be spoken of hereafter. Some of the rooms are provided with open fire-places. Complete toilet-rooms for male and female, representing a high order of sanitary art, are centrally placed on each floor.

With the exception of the single elevator above mentioned as being on the ninth floor of the building, all of the machinery, including engines, dynamos, pumps, etc., are located in the cellar, which is 15 feet below the ground floor.

STEAM TO ENGINES AND MACHINERY.

Referring to cellar-plan, it will be seen that the steam-boilers, 9 in number, are located in the wing of the building which runs toward Nassau Street. Here the steam for all purposes is generated and maintained at a pressure of about 80 pounds per square inch above atmosphere. It is carried direct to the dynamo-engine A, to three large hydraulic elevator steam-pumps B B B, the Knowles pump C, the three small duplex pumps D E F, the engine G that drives the four dynamos comprising a permanent electrical exhibit of the U. S. E. L. Co., whose offices are in the building, the engines H I that furnish the power to the Root blowers J K for pneumatic service, and the air-compressor L for the same; also the 13 steam elevators for kitchen and restaurant service located at M, and finally the steam-heating service of the building, direct, through reducing-valves T T, reduced to five pounds pressure, when the exhaust steam from the engines, pumps, etc., is not sufficient.

The system of elevator and other mechanism here represented was designed by and erected under the personal supervision of Mr. James F. Wilson, who occupies the position of superintending engineer, whose duties extend not alone to the New York or parent building, but also to the various buildings of the Equitable Life Assurance Society in other cities. He has held the position for 13 years and enjoys the entire confidence of the company; practically he was restricted in nothing, so that the Equitable engineering plant, of which we give very full illustrations, may be looked upon by our readers as a typical domestic plant of a New York building, there being presumably nothing of its class approaching it in magnitude in the world. It is proposed to explain the general working of the plant as a whole, and treat of each division separately hereafter.

Beginning at the boilers, the steam is taken off by the branches 1, 2, 3, 4, 5, 6, 7, 8, 9, each 6 inches in diameter and all connecting with one main steam-pipe, N, which from branch 2 to the end is 10 inches diameter; from branches 4 to 2 is 12 inches diameter, and from here to the 9th branch it is 14 inches diameter; from the elbow O, to the first of the 3 pumps it is 10 inches diameter; the remainder of the way it is 7½ inches in diameter.

The first branch taken from this main is that marked 10, which is 6 inches diameter and conveys steam to the 13 steam-elevators that are to carry waiters, dishes, etc., from the restaurant and cafe on the ground floor to the kitchen on the eight floor, also to the cafes of the several clubs on the fifth and sixth floors.

The next branch, marked 11, is 10 inches diameter and is the regular heating-main going around by the north side; the following one, marked 12, is also 10 inches diameter and is the heating-main for the south wall. These are shown and thus make the circuit of the

The main steam-pipe is next tapped at 13 by a 10-inch steam-pipe which conveys steam to the 450-horse-power Corliss engine, made by the Watts-Campbell Co., of Newark, N. J. Beyond 13 the main steam-pipe is reduced to 10-inch diameter and turns to the south, not only to avoid a wall, but to give the necessary bend for expansion. At 14 a 2½-inch pipe takes live steam to the laundry on the ninth and also to the kitchen on the eighth floor, also to a hot-water tank in the cellar for hot-water service of the building and janitor's uses.

Through a 4-inch pipe at 15 steam is taken off for the engine of the electric-light exhibit, located at B. At 16 a 3-inch branch (not shown) gives steam to the three Worthington pumps located at D E F. At 17, 18, 19 branches four inches in diameter convey steam to the three large elevator pumps, a side view of which will be hereafter. At 20 a 4-inch pipe takes steam to the shown Knowles duplex pump marked C, while the last branch 21 conveys steam to the engines H I L of the Pneumatic Service Co. The steam-main then continues on over the edge of the elevator water-tanks, P P, where it bends down into the tanks, the object being to open the valve 22 and quickly empty the steam-pipe when repairs are to be made. Following in like manner is the 10-inch exhaust-pipe, Q, from the three large pumps. This pipe receives the exhaust of the Knowles pump at C and the exhaust of the elevator pumps B B B.

At 24 a 10-inch branch turns northward toward the heater R and the main vertical exhaust-pipe S. From 24 the exhaust-pipe continues straight ahead, with exception of the expansion-bend U, until it enters the heating-main at 25; in the same manner the exhaust-pipe of the steam-engine A, 10 inches in diameter, goes direct to the heater R and from thence to main vertical exhaust-pipe S; also connects with heating main at 26. The "cross-over" pipe V is introduced to enable the exhaust of the several pumps, etc., to be carried over to the north wall of the building, and the engine-exhaust to go around the south side when found necessary. At 27 a heating-main of six inches diameter runs along in front of the boilers, carrying heat to Nos. 17, 19, and 21 Nassau Street.

The exhaust-steam from the engines and pumps is utilized in warming the building by a system of valves. The possible combinations for diverting the several exhausts are numerous and important. By closing valve 30 and opening valves 28 and 29 the exhaust from the three large pumps B B B, the three air-compressor engines, H I L, the engine of the dynamo exhibit G, also from the three small pumps D E F, go directly into the heating-main that follows the south wall of the building. By closing valves 29 and opening 30 and 31 those several exhausts go directly up the exhaust-pipe S to the atmosphere. By closing 32 and opening 31 it is then diverted into the heater R, where it is used to heat the feed-water for the boilers.

When this combination is in use the valve 33 is left open for final escape by way of valve 34. Valve No. 34 is a "Kieley" back-pressure valve, which allows all the surplus steam over five pounds pressure to escape up the exhaust-pipe S should the heating-mains not require it.

The exhaust steam from the main engine A is provided for in the same manner. When valve 35 is closed, and 36, 37, and 38 are open, the exhaust may go direct to the heating mains that follows the north wall of the building. When valves 36 and 39 are closed and 40 and 35 are open the exhaust may go direct into the feed-water heater R and escape to the main exhaust-pipe S by way of valve 34 as before. By closing valve 40 and opening 39 the exhaust steam has a clear passage to the atmosphere without going through the heater. The cross-over-pipe V is used when the north side of the building requires more steam than the south side and there is a surplus to spare, then the exhaust from the pumps, etc., can be diverted to suit the demands, the same as of the south side borrowing from the north in case of a like emergency.

At a point between the heater and the heating-mains a Stewart oil extractor is placed to prevent contamination of the feed-water and save the grease of the oil from the various cylinders.

The usual way of running during the cold season is with all of the above-mentioned valves open, more or less, with exception of 32 and 39. This insures the feed-water being heated by the several exhausts passing through the heater; the pressure throughout the mains being kept at five pounds pressure by the action of the back-pressure valve 34, and a general equalization of the pressure on the north and south sides of the building. During the sum-

mer season the valves 36 and 29 are closed to keep the exhaust steam out of the heating-mains, the proper combination of closed and open valves diverting it to the feed-water heater, or directly up the exhaust-pipe in case the latter is undergoing repairs, etc.

When the latter system or combination is in use the lever of the back-pressure valve is hung up for the season, which makes a free exhaust through the heater and up the exhaust-pipe S to the atmosphere.

On some occasions live steam is turned into the heating-mains through the globe-valves marked 41 and 42. Immediately adjoining those valves are placed reducing-pressure valves that allow automatically only the pressure for which they are set to pass through them—viz., five pounds. These valves are special "Kieley" make.

Thus in the steam-heating system the following is allowed for: (1) The heating of the building by live steam on holidays or Sundays when engines are not running; (2) heating by exhaust-steam from the various steam-engines and pumps when they are running; (3) heating by the use of both at once; (4) shutting off steam completely from the south side of the building by closing valves 29, 44, and the valve marked 45 located in the offices of the Mercantile Safe Deposit Co., under the Broadway sidewalk; (5) assisting either side by additional exhaust-steam as found necessary by means of the cross-over-pipe V.

(TO BE CONTINUED.)

A BATH-ROOM IN RESIDENCE OF MR. E. H. WALES.

We illustrate herewith a bath-room in which the novel feature consists in the placing of all traps and waste pipes above the floor and inside the room exposed and accessible. The only wood-work in the bath-room is the seat of the water-closet, the casing of the cistern, and the rim of the bath-tub.

All waste-pipes and water-supply pipes from the fixtures are brass, nickel-plated. All traps are above the floor and

city has resulted in the discovery of many violations of the plumbing and tenement-house laws which might otherwise have escaped notice. For example, during the week ending October 8 there were reported to the Chief Inspector 200 violations, or at the rate of about 10,000 yearly. The last week or two has also witnessed a considerable number of prosecutions and sentences, some remarkable for the determined effort to commit a fraud in the violation, others for the criminal and useless carelessness of the work complained of. In the case of Brandt Bros., for instance, it is difficult to see what expense was saved by the bungling way in which the work was done. Indifference and disregard of the future tenants and criminal neglect to secure good workmanship are the only apparent causes for this piece of work. That the builders are held to answer before Special Sessions is a good thing, calculated to have some effect in developing a sense of responsibility in other builders who might follow their methods.

One of the most objectionable cases is that of George C. Angell, a builder. Our readers will remember the fall, a few years ago, of a block of tenements built by Buddensieck, who is now, perhaps, learning more honest workmanship in the Penitentiary. These lots—on Sixty-second Street, near Tenth Avenue—were bought by Angell, who recently consulted with the Board of Health on the possibility of rebuilding on the Buddensieck plan, once approved by the board. He was informed new plans must be filed, as changes in the laws invalidated the old ones. One set of plans, then presented by Angell, were rejected, because they did not conform to the requirements of the law relating to air-courts, etc. Then Angell, about June 30, filed new plans, which were almost models. Of course they were passed by the board, and Angell began to build. But the inspector discovered that the buildings were going up in accordance with the plans which the board had rejected, showing a manifest expectation that the inspector would not detect the variation. A warrant was procured by the Board of Health, Angell was arrested, and then the board learned that he claimed to be building under the

BATH ROOM IN A NEW YORK CITY RESIDENCE.

are likewise brass, nickel-plated. The iron soil and vent pipes from the traps which pass vertically through the room are silver bronze. They are also entirely exposed on the face of the tiled wall. As will be seen, the slab is supported on brass standards, nickel-plated. The work is so arranged that all fixtures and plumbing-work can be removed from the room in a brief period.

This work was done in the house of Mr. E. H. Wales, 122 East Thirty-ninth Street, and the master plumber was Mr. Leonard D. Hosford, 66 Beekman Street, this city.

VIOLATIONS OF THE PLUMBING AND TENEMENT-HOUSE LAWS OF NEW YORK CITY.

THE increase in the number of inspectors in the Plumbing and Tenement Bureau of the Board of Health of this

Buddensieck permit of 1884. The case was heard September 6, and Angell was held on bail to go before Special Sessions.

Another "light-and-air" case is that of O. N. Donohue, who had tenements on Fifty-Fourth Street and Avenue A. In violation of the law, which requires each house to have its own light and air court or shaft, or yard, Donohue omitted the light and air shafts, making one house to open on other lands along the East River liable to be built upon, and another on a yard of another property. He was tried on October 6, at Special Sessions, convicted, and fined \$250.

A case now pending is that of George J. Harlow, a builder of tenements at 434 West Twenty-seventh Street. Harlow, after submitting proper plans, went on to build houses, omitting the light-shaft called for in his approved

plans and specifications. He also tried to evade the law by making "alcove rooms," or one room opening from another without its proper light and air, and had other violations of the tenement law. He was arrested September 21, taken before the Jefferson Market Police Court, and held, on bail, for trial at Special Sessions.

F. Donnelly, builder of a house on Eighth Avenue and Thirtieth Street, covered the entire lot with the building, in violation of his approved plans and specifications, which called for a vacant space of four feet in the rear, to meet the requirements of law. He was notified of the violation, but proceeded with the work, claiming that the architect had told him "it was all right." He was required to take four feet off of the depth and remodel the interior of the house to satisfy the law. His trial was had October 6 in Special Sessions; he was convicted, and fined \$100, the Court, in fixing the fine, taking consideration of the fact that he had removed the violation.

Juch (or W. Meany), a builder, filed plans for a certain number of tenements on Manhattan Street. Then he built one more house than he filed plans for, hoping the inspector would not notice the fact. This house, in violation of law, he extended to the rear line of the lot, and tried to persuade the inspector that the building was to be a factory, which would not come under the tenement requirements for light and air. But the board directed the inspector to keep an eye on the building. As the work progressed, it was discovered that each floor above the first was arranged to provide for families, and Mr. Juch's case was sent to the attorney of the board. He was then notified to take ten feet off of the depth of the house, and to make other alterations required by the law. At first he tried to shift the responsibility, then made terms, made the alterations, and has not been prosecuted.

In several other cases the attempt to evade the laws has resulted in the builders incurring heavy cost for alteration. Thus in the case of houses on Norfolk Street the builder tried to outwit the board by carrying the house one story higher than his specifications showed. He had to take down a wall, enlarge the air-shaft, and remodel the interior. Again, on East Twelfth Street, a builder has been obliged to take down a wall and to make his air-shafts of the size shown on the plans. The expense involved in these changes would repay, several times over, the carrying out of the requirements of the board. These violations are virtually an attempt to gamble on the board's stupidity, and the builders have been caught and severely stuck.

Several bad violations of the plumbing regulations have also been prosecuted. Brandt Bros., for example, builders of several houses on Eighty-fourth Street, east of Avenue B, sent word to the board that the house-drains or sewers were ready for inspection. But the inspector found what he considered an intent to deceive possibly both the board and the owners. The joints of the tile-drain were properly made on top of the drain-pipes, but no joints whatever were made on the under side; supposed to be out of sight of the inspector. Had the deception not been discovered here would have been several drains leaking their filth directly into the soil. A private sewer was also badly constructed, with open joints. The board ascertained that the drains were laid by direction of the builders, who were on October 3 held in bail for Special Sessions. This case, as noted above, seems to be explainable only on the ground of criminal carelessness, rather than on the ground of a desire to save part of the expense. A lesson of responsibility is taught by the prosecution.

J. G. Collins, plumber, did the plumbing-work in four houses on Ninety-fifth Street, east of Ninth Avenue, for Taylor & Post, owners. After the work was left for finished the inspector of the board found it to be bad throughout, particularly in the imperfect joints on the cast-iron pipe and the poor quality of fittings, etc. In the cellar of one house 10 open joints were found, and in the cellar of another 8 open joints. Collins was arrested October 8, and his case is still pending before Special Sessions.

H. Z. Norton, a plumber, was arrested, as we have noted in a previous issue, for putting in dummy vents. The result was that Norton pleaded guilty, and on September 28 was fined \$250.

Francis Callaghan, of 78 Fourth Avenue, produced some remarkable joints on vertical iron pipe. A specimen was taken into court on Monday of this week, while his prosecution was going on. The Board of Health inspector discovered that Callaghan had made nominal lead joints by twisting a roll of paper, which was placed in the rear of the hub out of sight. The front of the hub was filled with what appears to be light sheet-lead, crowded in and slightly hammered. The lead was extended partly over the paper to aid the fraud. But the inspector lifted the whole thing out and Callaghan's prosecution was begun. His case was on trial October 10.

ATTEMPT TO DECEIVE A BUILDING INSPECTOR IN CINCINNATI.

THE latest trick to deceive an inspector of plumbing that has come to our notice was one attempted on Mr. Walter R. Forbush, Inspector of Buildings in Cincinnati. He was notified that the plumbing work in a tenement-house on the corner of Front and Mill Streets in that city was ready to be submitted to the water test, which our readers will understand is done by plugging up the lower end of the drainage system and filling the pipes with water to ascertain if the joints are tight. Mr. Forbush, however, found that there was no water in the pipes, and on investigation he discovered that a plug had been inserted in the soil-pipe about ten feet from its terminal above the roof. Of course, this space of ten feet above the plug was filled with water. He then broke off the back-air pipe and found it also plugged in a similar manner, the plugs being made tight with asphaltum, with the result that the drainage system was deprived of all ventilation. We regret that we do not know the name of the rascal who attempted this piece of villainy, so that we might publish it. At any rate it will be a great pity if an attempt is not made to put him in jail. If he tried it in this city we think there is little doubt but that he would find himself placed there for a short period.

EFFECT OF GALVANIZED-IRON BOILERS ON WATER-SUPPLY.

NEW YORK, September 17, 1887

SIR: Will you be kind enough to inform me whether or not it is injurious to health to drink or use for cooking purposes the water from a galvanized hot-water boiler such as are used in flat-houses? YOUNG PLUMBER.

[Under ordinary circumstances, and with the Croton water-supply, there is no danger in the use of water from a galvanized-iron boiler. The zinc is slowly dissolved, and the quantity in the water at any one time is so small as to be harmless. With a new boiler, in which the water has stood for several days, enough zinc may be dissolved to give a perceptible taste, and such water would probably be injurious.]

It is always a wise precaution to let all the water run to waste which has been standing in water-pipes and boilers for a week or more before drawing water for drinking or cooking, because water which has thus stood in the pipes is apt to contain both lead and zinc.

With some water-supplies the corrosion of galvanized-iron pipes, boilers, etc., is very rapid for the first three or four days.]

Novelties.

Under this heading we propose to describe and illustrate appliances of probable interest to our several classes of readers. The selection will be made without reference to the wishes of agents or patentees, being governed solely by considerations of novelty, ingenuity, and probable interest to readers, and especially the fact that they have not been elsewhere described. As a rule we shall make no comments, and it is to be distinctly understood that a notice does not imply approval. No charge will be made for these notices, and any offer of pay for their insertion will insure their omission. We shall be glad to have our attention called to novelties suitable for this section.

RADIATOR HOT CLOSET.

THE accompanying drawings illustrate a novel hot closet or dish-warmer for use in dining-rooms or butler's pantries

lately invented and patented, George H. Dixon, steam-heating engineer, of Chicago, Ill.

The invention constitutes a hot closet or dish-warmer by itself, heated by the circulation of steam or hot water through its end parts, and also through its bottom, independently of any radiator tubes or other exterior mechanism. The hollow vertical end sections or elements are connected at their lower ends by ordinary screw-joints to the hollow base N, and where desirable they may be connected with radiator tubes at their top ends, in such a case being capped in an ornamental style, as shown, being substantially a radiator and hot closet combined.

The curved plates serve to make the closet of suitable width, and also as connecting-plates for the back and front door plates.

Shelves to the closet rest on projections formed on the insides of the side tubes, and on top there is a plate covering the closet. Steam when used enters the hollow base through the pipe connecting the radiator with the closet, and the water of condensation is discharged at the opposite end in the usual manner; or one of the openings may be plugged up and the steam enter and the water of condensation return through one and the same pipe under the ordinary single-pipe system of steam circulation.

When hot water is employed as the heating medium, the end sections of the closet must be connected at their tops by one or more small tubes, as shown by dotted lines, to attain a proper circulation of the water.

Correspondence.

All correspondents should send us their names and addresses, not necessarily for publication, but as a guarantee of good faith and because it is often necessary to communicate with them for additional information before printing their communications. Anonymous letters will not be noticed.

STREET-SWEEPING MACHINES WANTED.

BOARD OF HEALTH OF THE CITY OF ATLANTA,
OFFICE OF SECRETARY, 63 WHITEHALL STREET,
ATLANTA, GEO., October 7, 1887.

SIR: Will you kindly give me the address of several reliable manufacturers of street-sweeping machines if it is in your power to do so? Yours truly,

JAMES B. BAIRD, Secretary.

[Referred to our readers.]

EFFECT OF BOWER-BARFF PROCESS ON WATER-PIPE.

SIR: Is it absolutely safe to use Bower-Barff process rustless iron pipe for the water-supply of a house for drinking and all other purposes? I am thinking of so using it, but know very little about it. HOUSE-OWNER.

[We think so.]

NORFOLK SEWER SYPHON.

OFFICE CITY ENGINEER,
NORFOLK, VA., October 4, 1887.

SIR: My attention having been called to your notice of the last municipal report of this city, I beg permission to correct what is, in my opinion, an injustice (unintended, of course) to Colonel George E. Waring, Jr., whose system of sewerage has been adopted here.

The syphon therein mentioned was not "an improvement on Colonel Waring's original plan," as the discharge of sewage by gravity is certainly better than where gravity has to be assisted. It was a change necessitated by peculiar surroundings. It is due Colonel Waring, also, to state that the use of the syphon was suggested and recommended by him. Very respectfully,

W. T. BROOKE, City Engineer.

PLANT MILLING CO. BOILER EXPLOSION.

NEW YORK, October 11, 1887.

SIR: Some of the newspaper articles on the explosion at the Plant Milling Co. contained statements which would lead people to believe that the Babcock & Wilcox boiler may have exploded. Will you kindly give a place in your columns to the following, as it will serve to correct mis-statements, and oblige, very truly,

THE BABCOCK & WILCOX CO.

"The 'Firmenich' boiler at the mill of the Plant Milling Co., St. Louis, exploded October 3, destroying the boiler-house and wrecking the Babcock & Wilcox boiler by its side. As soon as the debris could be cleared away, and the facts investigated, a telegraphic order was sent to the Babcock & Wilcox Co. for two new boilers of 500 horsepower."

hemlock beams were above, but, so far as examined, show little or no indication of decay.

Whether this superior durability is owing to a difference in the nature of the timber, or to the longer seasoning that the spruce beams had received before being sealed up, cannot yet, if ever, be definitely known.

The character of the parties interested is such as to render it certain that the whole matter will receive a most searching and scientific investigation, but, meantime, enough is known to be a most valuable warning to any one proposing to use a similar construction.

Gas and Electricity.

Illuminating Power of Gas in New York City.

Week ending	New York Gas-Light Company.	Manhattan Gas-Light Company.	Metropolitan Gas-Light Company.	Mutual Gas-Light Company.	Municipal Gas-Light Company.	Ketchikan Gas-Light Company.	Equitable Gas-Light Company.
October 8,	25.16	20.88	21.76	29.47	31.00	23.27	29.76

E. G. LOVE, Ph.D., *Gas Examiner.*

THE heating and ventilating of the new building of the "Vereins Bank," in Munich, Bavaria, is the subject of an interesting paper in the *Gesundheits-Ingenieur*, by Dr. Frederick Renk. The paper is most interesting, because the building has been erected with the idea of embodying and completing in every way modern German ideas on these two most important subjects—heating and ventilation.

THE last number of the *Revue Industrielle* contains three rules, promulgated by the Committee of Public Health for France, relative to and specifying the colors that may and may not be used in the painting and decorating of children's toys. All arsenical colors and lead salts soluble in water are forbidden. Chrome yellows and similar compounds when used under varnish or with alcohol are permitted.

AT a meeting of the Gas Committee of the Glasgow Corporation, held on the 25th ult., it was agreed to recommend the Town Council to reduce the price of gas in the city, and also to outside consumers from 3s. to 2s. 10d. per 1,000 cubic feet. This is the third reduction in the price of gas which has been made during the last four years.—*Gas and Water Review.*

ACCORDING to the *Electrical World*, Mr. E. P. Thompson has devised a form of incandescent electric-lamp in which means are provided for preventing the disposition of carbon particles on the inner surface of the globe.

AMERICAN INSTITUTE OF ARCHITECTS.

THE twenty-first annual convention of the Institute will be held on Wednesday, Thursday, and Friday, October 19, 20, and 21, 1887, at Chicago, in the rooms of the Literary Club, in the Art Institute, corner of Michigan Boulevard and Van Buren Street.

The following is the order of proceedings:

First Day, Morning Session, 10 A. M.—(1) Opening address, by President Thomas U. Walter, LL.D., or, in his absence, by First Vice-President Edward H. Kendall; (2) Report of the Board of Trustees; (3) Report of the Treasurer, and appointment of Auditing Committee thereon; (4) Reports of the Standing Committees on (a) Education and (b) Publications; (5) Reports of the Chapters in Baltimore, Boston, Chicago, Cincinnati, Indianapolis, New York, Philadelphia, Rhode Island, San Francisco, St. Louis, and Washington; (6) Report of the Secretary for Foreign Correspondence; (7) Appointment of Nominating Committee for the election of officers and standing committees for the ensuing year; (8) Reports of special committees: (a) On bill to provide improved methods in the architectural service of the Federal Government; in conference with Special Committee of the Western Association of Architects; (b) On Architects' Protective Associations; (c) On providing a permanent home for the institute; (d) On a building contract for use throughout the United States; in conference with Special Committee of National Association of Builders, U. S. A.; (9) Appointment of special committee for the consideration of all reports presented to the convention; (10) Communications, announcements, and miscellaneous business.

Recess.

The Convention, as the guests of the Chicago Chapter of the Institute, and the Illinois State Association of Architects, will, after each morning session, take lunch together; and, on such afternoons as may be announced at the first session, their hosts will drive them to points of architectural interest in the city and its vicinity.

Evening Session, 8 P. M.—Exhibition of illustrations of work executed, within the last ten years, by such practitioners as may have responded to the official invitation to

letter of 1st ultimo, to Institute Fellows and Associates, to whom it is herewith re-enclosed.

Second Day, Morning Session, 10 A. M.—(1) Unfinished Business; (2) Amendments to By-Laws; (3) Report of Nominating Committee; (4) Report of Special Committee, for the Consideration of Reports; (5) Election of Officers and Standing Committees; (6) Reading and Discussion of Papers. The following papers, among others, on themes suggested to the authors, have been promised; and several are already in the hands of the Committee of Arrangements: By Mr. D. Adler, Fellow, on "Theatres." By Mr. M. E. Bell, Fellow, late Supervising Architect of the U. S. Treasury Department, on "The National Building Question." By Mr. W. W. Boyington, on "Differences Between the Methods of Architectural Practice Prevalent Now and Fifty Years Ago." By Mr. D. H. Burnham, Fellow, on "Suggestions toward the best and speediest methods for harmonizing and utilizing all the architectural societies in the United States, so as to secure the most good for architecture, for the public and for the profession in America; due regard being had, as concerns means, alike to individual energy and enthusiasm, and to associative experience; and, as concerns ends, alike to local sentiment and to national reputation." By J. C. Cady, Fellow, on "Opera-Houses." By Mr. Charles H. Harn, on "Manual Training as Applied to the Building Arts." By Mr. John Moser, Fellow, on "Federal Buildings for Judiciary, Customs and Postal Service." By Mr. J. L. Smithmeyer, Fellow, on "Library Buildings." By Mr. J. M. Wilson, Fellow, on "Where the Line of Demarcation Between Engineering and Architectural Practice is to be Found." (7) Communications, Announcements, and Miscellaneous Business.

Recess. Lunch.

Evening Session, 8 P. M.—(1) Unfinished business; (2) reading and discussion of papers continued; (3) communications, announcements, and miscellaneous business.

Third Day, Morning Session (only), 11 A. M.—(1) Unfinished business; (2) reading and discussion of papers concluded; (3) miscellaneous subjects and discussions; (4) general business, communications, announcements, resolutions of thanks, and adjournment.

The committee announces that there are two eligible hotels—on the European plan—in the immediate vicinity of the convention's place of meeting; one the Leland Hotel, Michigan Boulevard, corner Jackson Street, where rooms may be had from \$1.50 per day upwards; the other, the Richelieu Hotel, Michigan Boulevard, between Jackson and Van Buren Streets, where luxurious quarters may be had at from \$2.50 to \$20 per day.

Visiting members will find, at the meeting-room of the convention, a visitors' book, in which they are particularly requested to register, promptly on arrival, their addresses both at home and in Chicago; residents of Chicago will also please register.

Although, owing to the impossibility of getting the promise of attendance at the Institute conventions in sufficient numbers, as well as to the widely separated points from which members—often but a single individual from one place—start for the point of meeting, it has hitherto been found impracticable for the successive committees of arrangements to secure a general system of reduced rates for railroad travel; it is nevertheless suggested—and it has indeed been found feasible in several cases heretofore—that, if the various chapters, each in its own locality, will organize a visiting delegation to the convention, they may, through their local business and social connections, induce the railroad officials, in their several places of residence, to reduce rates for a dozen, or even for half a dozen friends or acquaintance to a figure which would be refused to an isolated individual, and a proposition for which, unless on the understanding of tickets being taken by the hundred, as usual where conventions are concerned, would receive no attention whatever if made by a distant Committee of Arrangements.

All reports or communications for the Committee of Arrangements should be mailed to the Secretary, A. J. Bloor, 18 Broadway, New York, or they may be forwarded direct to Mr. Henry Lord Gay, 15 East Washington Street, Chicago. He will also, on account of the Institute, receive illustrations for the exhibition hereinbefore mentioned, and an invoice thereof should be mailed to him.

W. L. B. Jenney, E. T. Littell, Henry Lord Gay, A. J. Bloor, Committee of Arrangements.

PERSONAL.

PROF. CHARLES F. CHANDLER, Dean of the Faculty of the School of Mines, Columbia College, New York, has just returned from Europe.

MR. E. H. WALKER, for many years Statistician of the New York Produce Exchange, has joined the editorial staff of *Bradstreet's*, to which paper he will give his exclusive services.

GEORGE B. BURBANK has been assigned as Division Engineer in charge of the Sixth Division, New York New Croton Aqueduct, consisting of the East Branch Reservoir and the Sodom Dam and Reservoir.

MR. H. W. BRINCKERHOFF, M. Am. Soc. C. E., has accepted a position on the editorial staff of THE ENGINEERING AND BUILDING RECORD. This notice is repeated, as the initials were accidentally transposed in our last issue.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITIONS.

NEW YORK CITY HALL ADDITION.

The Board of Sinking Fund Commissioners of New York City have adopted a resolution calling for competitive plans for a new building to accommodate the municipal departments and the criminal courts. Plans are to be submitted before March 1, 1888, and the following premiums are offered: First, \$5,000; second, \$4,000; third, \$3,000; fourth \$2,000, and fifth, \$1,000.

The building is to be six stories high in the form of two wings, one fronting on Broadway and the other on Park Row, leaving the space in the rear of the present City Hall as an open court with provision for free passage at the four corners.

Plans embodying the views of the committee have been prepared by Major McLean, City Engineer.

The Park Row wings will front 191 feet on Park Row and to be 180 feet deep, and will contain 10,770 square feet of room space. The Broadway wings will front 220 feet on the street, be 160 feet deep, and have 15,143 square feet of rooms.

Competitive plans must give the elevation of the proposed wings on each of the four sides and on the inner court, and must be accompanied by floor plans and specifications, with an estimate of cost. The Sinking Fund Commissioners are to be the judges of the plans, but the acceptance of any plan does not insure the employment of its designer as architect.

Lithograph copies of the general plan will shortly be prepared.

BRANTFORD, ONT.—The City Corporation ask architects to submit plans for a House of Industry and Refuge for ninety inmates, with barn, etc. The premium is \$50. Address S. Hewitt, Chairman of the Competition.

SCHOOL-HOUSE PLANS.—Architects of New York State are invited to submit competitive plans for six school buildings, for which \$975 is offered in prizes. The time of competition limited to December 1, 1887. Address A. S. Draper, State Superintendent, Albany, N. Y.

TRADE CATALOGUES.

THE DEANE STEAM-PUMP COMPANY, of Holyoke, Mass., has just issued a handy little catalogue describing and illustrating the various forms of steam-pumps manufactured by them and also quoting prices. The book contains in addition some useful information accompanied by several tables, showing "areas of circles," "friction of water in pipes," "probable thickness, weight, dimensions, etc., of cast and wrought iron pipes," etc.

We have received from Messrs Rutzler & Blake, 176-178 Centre Street, New York, their illustrated price-list for 1887 of "Improved Steam Specialties."

CHARLES MILLER & SON, lead pipe manufacturers, have issued a little catalogue in which the section of each size and weight of lead pipe is lithographed, full size, from 1/4 to 2 inches.

We have just received from the New York Iron Roofing and Corrugating Company, 115 Broadway, New York, their illustrated catalogue for 1887.

For works for which proposals are requested see also the "Proposal Column," pages 537-543-544.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE ENGINEERING & BUILDING RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

WATER. SEWERAGE. ETC.

MINNEAPOLIS, MINN.—Bids recently opened on pumping-engine for North Minneapolis. The Water Committee has referred them back to Council.

MINNEAPOLIS, MINN.—City Council has extended the time for receiving bids on pumping machinery forty days. The action was taken October 7.

LANCASTER, PA.—The contract for erecting the new building for the water-works has been given to Amos S. Urban, of that city, at \$17,750.

After awarding the contract for water-works to Amos S. Urban at above price (\$18,750) he informed the Council Committee that he had made a mistake in his computations, and the bid was lower than he had intended it to be. City Council at once decided to readvertise.

GREENBUSH, N. Y.—Messrs. Landreth, Fitzgerald & Prescott, of Schenectady, have finished the plans for the Greenbush sewers, and have presented them to the village fathers. The cost of the system complete will be about \$70,000.

BURLINGTON, VT.—A main sewer will be built at once in King Street.

GLENWOOD SPRINGS, COL., will have water-works completed by November.

SEVILLE, FLA.—The sewerage system is being extended.

MARBLEHEAD, MASS.—The water-works at Marblehead that have been tried and proved to be inadequate for fire purposes, will be remedied by the company putting in a larger main. The town will also consider at an early day the extension of the water works throughout the town, affording a supply for both fire and domestic purposes.

JERSEY CITY, N. J.—Another water-supply proposition was received by the Board of Public Works, October 11, from George H. Titcomb, who offers to deliver water at Belleville at the rate of \$32 per million gallons. He claims that he is able to build a \$5,000,000 plant within fifteen months. He says the city may purchase the plant any time within ten years at the cost of construction plus five per cent. The matter has been referred to the Committee of the Whole.

MILWAUKEE, WIS.—See our Proposal Column for information regarding pumping machinery wanted at this city.

BOWLING GREEN, O.—Our correspondent writes: "The vote to authorize the operation of water-works in the village of Bowling Green, O., resulted as follows: for, 179; against, 163; majority for, 16. Only a light vote was polled."

EL PASO, TEX.—El Paso is at present constructing a sewer system according to plans and under the superintendence of George Waring, C. E. The sewage of the city is intended to be discharged into the Rio Grande at a point a short distance below the city limits. The work is progressing rapidly and will soon be finished.

NORTH EASTON, MASS.—Our correspondent writes: "Village District of North Easton has appropriated \$75,000 to build water-works. Works are half completed. About six miles pipe, sixty hydrants, stand-pipe and large collecting-well, yielding a very pure, soft, spring water. Works will be in commission December 1, 1887."

PONTIAC, MICH.—Our correspondent writes: "A special election held and \$75,000 voted for construction of water. No definite action further than the appointment of a Board of Water Commissioners has been taken."

LOWELL, MICH.—The Lowell Water Company, previously noted, is progressing towards giving the village a supply of water. The company is composed entirely of Grand Rapids capitalists. They are putting in a system on the reservoir plan. The reservoir is located on the hill, north-east of the village, and has a capacity of nearly 1,000,000 gallons. The water will be obtained from twenty tubular wells. Their average depth is twenty-five feet. The pumping-engines to be used are of the Smith-Vaile duplex pattern. Four miles of pipe will be used.

ALTOONA, PA.—The Water Commissioners ask that \$25,000 be offered to lay a water-main to Kittanning Reservoir.

TORONTO, ONT.—Superintendent Hamilton, of the water-works, has prepared for the Aldermen a new plan for increasing the water-supply. It provides for additional 4-foot iron mains, to connect the pumping-station with the 6-foot main.

MILWAUKEE.—The Common Council, at its next meeting, will instruct the Board of Public Works to advertise for bids to construct the flushing-tunnel under Dane Place.

OMAHA, NEB.—Our correspondent writes: "Our town ranks as a metropolitan city of 100,000 inhabitants. We have had water-works in successful operation since 1881. The company are at present enlarging their facilities. The works are not under control of the city government."

STROMSBURG, NEB.—Our correspondent writes in regard to water-works: "Bids to be open for a \$12,000 system on October 15."

FORT COLLINS, COL.—In regard to the rumored construction of water-works here our correspondent writes that "the works were completed and have been in good working order since 1883." C. B. Parsons is water-works superintendent.

CHICAGO.—City Engineer Artingstall has about completed plans for the 4-mile tunnel, eight feet in diameter, for new water-works, the tunnel to start from the Lake Park on the South Side. The site for pumping-works is not yet chosen. The improvement, it is popularly estimated, will cost \$1,500,000.

WEST DEPERE, WIS., will have a system of water-works.

SALT LAKE CITY, UTAH.—City Council is considering plans for sewerage.

NEW ORLEANS, LA., is receiving bids on artesian wells for water-supply; from the American Well-Drilling Company, of Louisville, Ky., for example.

NEW ORLEANS, LA.—The City Surveyor will prepare plans for work on certain of the canals and levees. It is expected the work will be done before the winter rains set in.

MOBILE, ALA.—The Common Council held a meeting October 7 for the purpose of considering the Bienville Water-Supply Company's proposition to furnish 100 fire-hydrants, to be located by the Chief of the Fire Department, for one year at \$50 each. The ordinance was amended by putting the power of locating the hydrants in the hands of the Street and Fire-Engine Committee and the Chief Engineer of the Fire Department, instead of the Chief solely, and, as amended, was adopted.

WEST HARTFORD, CONN.—A committee has been appointed to consider sewerage for the West Side. Address the Town Clerk.

GLASTONBURY, CONN.—Yesterday a meeting was held at the Town Hall to devise more perfect meadow drainage. Address the Glastonbury Meadow Drain Company.

GRIFFIN, GEO.—Our correspondent writes: "No steps have been taken as yet, except the sanction of the State Legislature, to assess a special tax for this purpose. Before the system can be inaugurated a two-thirds majority vote of the citizens will be necessary. No date has been fixed for this election, though I think it will be early in December."

HUMMELSTOWN, PA.—Our correspondent writes: "The Town Council has agreed to accept sixteen plugs at \$35 per annum for ten consecutive years. The works are to be completed April 1, 1888."

MONTREAL, CAN.—City Council has approved the reports of the Water Committee recommending the appropriation of \$67,000 for high-level pumping apparatus and water-mains.

SYRACUSE, N. Y.—Common Council has ordered the construction of a 60-inch brick sewer in Crotton and other streets to Onondago Creek, at an estimated cost of \$26,000. Address H. W. Bannister, City Clerk.

GALLATIN, TENN.—Our correspondent writes: "Nothing on our prospective water-works at present; will be nothing done about it for six or eight months."

JOHNSON CITY, TENN.—The City Council has made arrangements to put up water-works here, and to commence in the next ninety days, but has done nothing yet. Time will be up in November.

LAKE CITY, FLA.—Our correspondent writes: "A charter has been granted to Noyes S. Collins for twenty-five years to construct and maintain a water-supply for this town. He has already begun operations, using present works, but will enlarge."

SHELBYVILLE, ILL.—The Shelbyville Water Company increases its stock from \$7,000 to \$100,000.

KALAMAZOO, MICH.—In our Proposal Column will be found a reference to the construction of a well for the water-works.

WINONA, MINN.—On October 4 Council voted to purchase a 2,000,000-gallon pumping-engine, and to ask bids for sinking a large well.

FOSTORIA, O.—Our correspondent writes: "As yet there has been no definite action had in reference to water-works. An ordinance has been passed granting franchise, which must yet be ratified by a vote of people, and the special election has not been called, and will not be had until some minor matters have been arranged with the contractors, and until they file an acceptance as provided for in ordinance. Can, therefore, not give you any definite information."

UNION GROVE, WIS.—Our correspondent writes: "We are only boring artesian wells for fire protection. We have let the boring of the same to Gray Gray Brothers, of Milwaukee, Wis., but we have done nothing regarding pipes and hydrants as yet."

ST. ANDREWS, N. B.—We call attention to the construction of water-works here. See our Proposals.

CLINTON, ILL.—At a special meeting of the City Council, October 4, the contract for supplying the water-works with pipes, special castings, hydrants, gates, and pumps was let, and will involve an expenditure of about \$6,000. The complete system will require about \$10,000. The cost of the well, which is now finished, was \$3,000.

CORSICANA, TEX.—\$25,000 will be spent on sewers and other works.

MACON, GEO.—It is proposed to spend \$60,000 on sewers, etc.

ONEIDA, N. Y.—Surveys are being made for sewers. Address the Town Clerk.

GALLIPOLIS, O.—Our correspondent writes: "The Council of this city have passed an ordinance submitting the question to a vote of the people, as to whether the Council shall issue bonds to the amount of \$50,000 for the building of water-works. The vote will be taken on November 8."

KINSLEY, KAN.—The contract for construction of water-works for city of Kinsley, to cost about \$40,000, was let to D. Mitchell & Co., Dodge City, Kan., September 20, works to be completed by January 1, 1888. Will use the stand-pipe system. Contract calls for two duplex pumps of 750,000 gallons capacity each. Work will be begun immediately.

BAR HARBOR, ME.—C. H. Eglee, of Flushing, N. Y., has been awarded contract for laying water-pipe of the Eden Water Company, about eleven miles, varying in size from 6 to 24 inches. E. W. Bowditch, C. E., of Boston, being the engineer of the work to be done there.

DAVID CITY, NEB.—Our correspondent writes: "The city of David City, Butler County, Neb., has voted \$22,000 in 'water bonds,' which are now for sale, for the construction of a system of water-works. The contract has been let to a contractor of Columbus, Neb., and is to include Cook's patent tube wells (27-inch) and hydrants. The stand-pipe will be 110 feet in height; direct-pressure engine in connection with stand-pipe. About three miles of mains are to be completed by December 31. Plans and specifications were furnished by A. A. Richardson, of Lincoln, Neb. The contractor expects to commence work within ten days."

NEW ROCHELLE, N. Y.—Our correspondent writes: "This town is to be supplied with water by the New Rochelle Water Company which the capital stock of is almost entirely owned by A. Iselin, Sr. The reservoir is already built and the pipes are all laid throughout the village; and a commission which was appointed to assess damages for laying the pipe through some farms from the reservoir have filed their report, and the main pipe will be laid immediately, so we shall have water in the spring or before."

TOWSONTOWN, MD.—Incorporated is the Consumers' Water and Illuminating Company, of Baltimore County, to supply water and gas to the towns of Woodberry, Woodlawn and Hampden. The directors are J. D. Mallory, R. J. Capron, W. M. Busey, George B. Morton, and William H. Watkins.

HELENA, MONT.—The Iron King Water Company is incorporated by Frank Tibbals and others.

RUSHVILLE, NEB.—Our correspondent writes: "Our village has contracted for the construction of a \$3,500 system of water-works, with the U. S. Wind-Mill and Engine Company of Omaha, to be completed by December 1, 1887, for fire protection and domestic use. We have 1,500 inhabitants, is the county seat of Sheridan County, and are constructing a \$5,000 school-house. The town dates from August 15, 1885, and promises to be one of the leading towns of north-western Nebraska. The Government freight-house for the Pine Ridge Indian Agency is located here. The Board of Trade is figuring with Eastern firms with a view of starting a cracker factory, a starch factory, and cigar factory here. We have a steam-roller, flour-mill, 200-barrel capacity, two brick-yards, and a boom."

ESSEX, VT.—Town meeting to-day votes on raising funds for village improvements.

KEWANEE, ILL.—Our correspondent writes: "The laying of water-pipe is nearly completed and the well will be finished in two weeks. Expect to furnish water December 1, 1887."

KEOKUK, IOWA, has decided to expend \$75,000 in a system of sewers.

BOSTON.—The Aldermen have refused to vote the \$100,000 asked for by Mayor O'Brien for new sewers.

COLDWATER, MICH.—Mr. Mason L. Brown, Civil Engineer, of Detroit, has completed plans for a system of sewerage and water-works for this city. Work to begin next year.

GRAND RAPIDS, MICH.—T. A. Parrish, of Grand Haven, has proposed that a pipe-line be laid to Lake Michigan to supply Grand Rapids with water.

JERSEY CITY, N. J.—The Board of Aldermen will have a hearing on plans for water-supply at the City Hall, Tuesday, October 17.

GREENVILLE, MICH.—This town has voted to bond itself for \$25,000 for water-works.

EAST TAWAS.—It is stated that the water-works here will be built by the Michigan Pipe Co., of Bay City, for \$28,000.

WATER COMPANY.—The Colorado City Water Company has filed articles of incorporation. Anthony Bott, Jacob Becker and John Campbell are the incorporators. Water is to be taken from Sutherland Creek, in El Paso County. The capital is \$200,000.

MORRISON, ILL., will have water-works.

MACHIAN, ME.—P. Rose, hydraulic engineer, has reported on water-supply. He favors either Lily Lake or two spring streams, with pumping-works and a dam at Lily Lake, to create a reservoir with a capacity of 22,000,000 gallons.

HOLMES CITY, COL., will have a water-supply from a flowing well.

EUPAULA, ALA.—Work has been begun on the water-works plant for this city.

CHARLOTTE, N. C.—The contract with the water-works company for erecting works here has been annulled, and the city has instructed the committee to advertise for new bids. Address F. B. McDonnell for particulars.

CARPENTERIA, CAL.—Our correspondent writes: "There is a regular chartered water company—Carpenteria Water Co.—at this place, but owing to litigation it has not done a great deal toward distribution; will do so shortly."

MACHIAS, ME.—In regard to water-works our correspondent writes: "No action yet by the town. Citizens are working by committee to report hereafter."

BROOKFIELD, MASS.—Our correspondent writes: "At town meeting of October 4 the town voted to put in water for fire purposes. A committee was also chosen who are to make a report at an adjourned meeting to be held Saturday, October 15, in regard to best means of obtaining the water, estimated expenses, etc. They will probably put in water for other purposes besides fire."

HENDERSONVILLE, N. C., contemplates building water-works.

AUSTIN, TEX.—A permit has been applied for by Silvester Watts and others for the purpose of building gas, water and electric light works.

WEATHERFORD, TEX.—The Weatherford Water, Ice and Light Company has been incorporated; capital stock, \$500,000. R. W. Kindel, R. F. Starr, S. Newmeyer, D. C. Haynes, R. R. Coleman, Henry Warrell, and Boyd Porter, incorporators.

MANCHESTER, VA.—A proposition has been made by Messrs. Ferris & Holladay, of Jersey City, to build water-works. The Finance Committee are considering the erection of a water-tower with a capacity of 500,000 gallons.

LAKE, ILL.—Proposals for pumping-engines were opened by the Town Trustees October 4. Up to the 11th inst. no definite action had been taken. We have not yet been able to obtain the bids.

ANDERSON, CAL.—A system of water-works will be erected here by the Anderson Water Co.

CHARLESTON, W. VA.—The Charleston Water-Works Company are building a filtering-basin 25x50 feet.

FAYETTEVILLE, N. C.—Proposals will be received until November 1 for building water-works. Address F. R. Rose, Fayetteville, N. C.

BLOUNTSVILLE, ALA.—Messrs. Doyle & Hudson, of this city, want 1,800 feet of 1½ or 2 inch water-pipe.

GAS AND ELECTRIC-LIGHTING.

BRAINARD, MINN., was illuminated with electric-lamps October 4.

LOUISVILLE, KY.—The Enterprise Natural Gas Company is developing a plant, and has struck gas at its well on Third Street. Mayor W. H. Coen is President, Harry Weissinger, Vice-President.

HARTFORD, CONN.—The question of street-lighting has not yet been settled. A report from the committee was received on the 10th inst., and ordered printed. It will come up for action at the next meeting. Immediate attention is desirable.

MIDDLETOWN, CONN.—The Schuyler Electric-Light Company will remove its works to Middletown, from Hartford. Works will be built.

ONALASKA, WIS., will have gas-lighting, taking the gas from the La Crosse works.

PHILADELPHIA.—The Columbia Natural Gas Company, developing wells and plant near Bradford, has passed into the control of the Natural Gas Trust of Philadelphia. James E. Salter, of Philadelphia, is President of the Columbia; James Miller, of Franklin, is Secretary.

FREDONIA, KAN., will have electric-lights, using the Thomson-Houston electric-light system.

HOULTON, ME.—The plant of the Thomson-Houston Electric-Lighting Company has been purchased by citizens, to be transferred to the water company.

CLEARFIELD, PA.—A company has been formed to sink gas-wells and erect a plant.

JERSEY CITY, N. J., wants better street lighting. Address the City Clerk.

FALL RIVER, MASS.—After to-day there is no appropriation for continuing the lighting of the streets, and new arrangements, both for gas and electric lighting, will have to be made.

PHOENIX, N. Y.—A special election is called for October 18 to determine whether the taxpayers are willing to accept the proposition of the Electric Light Company to furnish twenty arc lights one year for \$1,000.

AUSTIN, TEX.—The City Council has granted authority to the Austin Water, Light, and Power Company to erect poles and maintain electric-lamps.

KANKAKEE, ILL.—Incorporated is the Kankakee Electric Company by W. S. Read, J. H. Searer, and others.

STOCKTON, CAL., wants bids on street-lighting. See our Proposals.

PHOENIX, N. Y.—The contract for lighting the streets of Phoenix has been submitted to the Village Board. The company agrees to put in six more lights, making in all twenty, for \$1,000 a year.

AMSTERDAM, N. Y.—The Amsterdam Common Council has decided to erect 67 arc-lights of the Thomson-Houston electric system in the streets. The cost is \$6,683.25 per year for 67 lights of 1,200 candle-power each.

ST. PAUL, MINN.—City Convention, October 7, passed the ordinance granting to the National Subway Company authority to lay underground conduits for electric wires.

ELIZABETH, N. J.—Street Committee has recommended that the Westinghouse Electric-Light Company be granted a franchise. The other competitor for the street-lighting is the Schuyler Electric-Light Company.

MIDDLETOWN, O.—The Middletown Gas Company is incorporated.

LEAVENWORTH, KAN., parties have contracted with a Mr. Reed, of Ohio, to sink a gas-well 3,000 feet; price, \$10,000. Boring has just been begun, and it is expected that by January 1 the plant will be well completed.

LIMA, O.—Much gas-pipe will be needed to lay the distribution of natural-gas supply, which has just been carried to the city from the gas-fields. Address the City Engineer for further information.

NEW ORLEANS, LA.—Council has authorized Mayor J. V. Guillotte to contract with the Louisiana Electric-Light Company for five years to light the public buildings.

HUDSON, WIS.—S. H. Pierce, proprietor of the Hudson electric-light plant, has made a proposition to the City Council to light the principal streets. The proposition will be accepted.

FARMINGTON, ME.—The Dirigo Gas-Light and Heat Company of Maine, has been organized. Directors, Franklin J. Clark, B. M. Hardy, John J. Linscott, Seth E. Beedy, and Arthur E. Beedy. The purpose of the company is to furnish gas-light and heat by means of gasoline. Address the President, Dr. J. J. Linscott.

ORANGE, N. J., is still undecided about the granting of franchises for electric lighting. The matter is now referred to the Street-Lighting Committee. Address Mayor Hartford. Immediate attention is necessary.

ST. LOUIS, MICH.—Colonel John A. Elwell and others have formed an Edison Electric-Light Company.

CHICAGO.—People's United Gas Construction Company of Chicago; capital stock, \$100,000; to manufacture and sell gas for illuminating and heating purposes; incorporators, Elias Beach, Ezra Seaver, and E. D. Clark.

BALTIMORE, MD.—The Baxter Electric Motor and Manufacturing Company have purchased ten acres of land and will build new works.

MACON, GEO.—The Jeter and Boardman Water and Gas Association have been chartered, with capital stock of \$50,000, for the purpose of building and operating gas and water works and electric-light plant. The incorporators are W. A. Jeter, of Brunswick; J. S. Schofield, of Macon; J. W. Wilcox, and James H. Campbell, of Macon.

LAKE CITY, FLA.—N. S. Collins will erect an electric-light plant for street-lighting here. Address him at the Lake City Bank.

JACKSON, TENN.—The Citizens' Electric-Light Co. of this city will erect a plant.

WEST CHESTER, PA.—Council has awarded the contract for lighting the streets to the Electric-Light Co. at \$15 per lamp per annum, for three years.

ALBINO, ORE.—Address C. B. Belling and Joseph Paquet in regard to electric-light plant to be erected here.

LAKE, ILL.—The bond of Economic Light and Heat Gas Company has been filed, and the company will supply gas.

STEAM-HEATING, BUILDINGS, ETC.

OYEMAW COUNTY, MICH., will vote on bonding for \$20,000 for county buildings.

STANTON COUNTY, NEB., will vote on raising money to build a jail.

JERSEY CITY, N. J.—A contract was signed October 6 for the rebuilding of the U. S. Express stables, corner of Henderson and Eighth Streets. The contractor is Charles Bouton, of New York. The building will cost about \$90,000. The plans and specifications were prepared by architect Lewis H. Broome, who will have supervision of the work.

LOUISVILLE, MISS.—Proposals are out for constructing a Court-House.

APPONANG, R. I.—Steam-heating apparatus is wanted by the Town Council (Warwick) for the Town Asylum. Bids will be received until October 24. Address the Town Clerk at Warwick.

BUILDING IRON WORK.—Among the proposals for the County of Duval County, Fla., are those for the iron work. See our Proposal Columns.

JACKSONVILLE, FLA.—On October 8 the Merrill-Stevens Engineering Company filed articles of incorporation. This company is composed of Messrs. A. D. Stevens, President; H. C. Pike, Secretary; W. L. Lamkin, Treasurer; Eugene Merrill, Manager of the Forging Shop, and Alexander Merrill, Manager of the Boiler Shops. Buildings will be erected and machinery is wanted.

CANON CITY, COL.—Chief Engineer A. A. Robinson, Santa Fe R. R., has located the passenger depot at the foot of Fourth Street, and the freight depot foot of Third Street. The buildings will be erected at once and stockyards also constructed.

CHATTANOOGA, TENN.—The newly incorporated Emory Coal and Railroad Company will develop a large property near this city—coal mines, railroads, buildings, gas-plant, etc. Incorporators: J. H. Parker, Paul R. Albert, W. J. Willingham, and others.

ST. PAUL.—After a municipal contest of six weeks the contract awarded to A. O. Noepel, of Des Moines, Iowa, for steam-heating the new City Hall and Court-House, and which failed of confirmation last week, has been confirmed by a joint meeting of the City Council and Court House Commissioners.

BRIDGES.

BRIDGE.—An iron bridge will be built over Middle Creek, Tremont Borough, Pa. Address proposals to John Healy, Commissioner of Schuylkill County, Pa.

HARRISBURG, PA.—City Council has appointed a committee to confer with the Pennsylvania Railroad in regard to the construction of overhead bridge in the city of Harrisburg.

FOND DU LAC, WIS.—The following bids for an iron bridge on Arndt Street were received by the Common Council of said city, October 3:

E. A. Spalding, Dubuque, Iowa, \$710.
King Iron Bridge and Manufacturing Company, Cleveland, O., \$1,075, with iron piers.
Kansas City Bridge and Iron Company, four plans—plan A, \$695; B, \$689; C, \$635; D, \$600.

Wisconsin Bridge and Iron Company, two plans—A, \$650; B, \$590.

Groton Bridge and Manufacturing Company, four plans—plan A, \$585; B, \$700; C, \$780; D, \$875. The three latter plans contemplate iron joists.

A. Y. Bayne & Co., of Minneapolis, three plans, designated by weight, at \$600, \$645, and \$695.

Massillon Bridge Company, Massillon, O., two plans—No. 1, \$550; No. 2, \$580.

Wrought-Iron Bridge Company, Canton, O., four plans—A, \$625; B, \$567; C, \$500; D, \$465.

Milwaukee Bridge and Iron Works, presents two plans, both same price, \$620.

P. E. Lane, Chicago, \$675.

The bids were referred to Committee on Public Improvements of Common Council. Contract will probably be awarded at a meeting to be held October 10.

MONTGOMERY, N. Y.—Our correspondent writes: "We are now building a new iron bridge of two spans of 110 feet each or 220 in all. Bridge will be completed about October 25. The stone-work is very fine. The bridge is being built by the East Berlin Bridge Co., of East Berlin, Conn."

WALTHAM, MASS.—Our correspondent writes: "Our Aldermen have adopted a plan for a stone bridge to cost about \$33,000, but have gone no further. The next step is to authorize its construction and make the appropriation therefor."

CHESTNUT HILL, PA.—The Engineer of Montgomery County has awarded the contract for an iron inter-county bridge over the Wissahickon, near Chestnut Hill, to Dennithorne & Son.

GENEVA, October 12.—Our correspondent writes: "We have built five bridges this summer, and we have two more to build this fall. The Town Board has appropriated \$4,300 for bridge purposes this year."

LEAVENWORTH, KAN.—A movement is on foot here for a new bridge over the Mississippi River. The company has obtained a charter and had plans prepared. Immediate attention is necessary.

DETROIT, MICH.—City Council has voted to award the contract for the Belle Isle bridge to the Milwaukee Bridge and Iron Company, at \$295,000, with the proviso that the city may select the \$305,000 plan.

ELIZABETH, PA.—The Elizabeth Bridge Company organized October 6 by the election of Captain W. W. O'Neil, President; Dr. P. T. B. Shaffer, Secretary. The capital stock will be \$100,000.

CHICAGO.—Bridge construction at three points: For the Dearborn Street substructure Fitzsimons & Carroll will receive \$30,000 from the North Chicago Street Railroad Co., who will themselves remove to this point the present superstructure of Wells Street bridge. For the new Wells Street bridge Fitzsimons & Carroll do the substructure for \$59,000 and the superstructure for \$86,750 (a 4-track bridge). For the Eighteenth Street bridge Joseph Downey does the substructure for the Western Indiana Road on private contract and the Keystone Bridge Co. the superstructure for \$58,000.

BRIDGES.—We note the following: At Northampton, Mass., a bridge to carry South Street over the New Haven and Northampton Railroad. The cost will be about \$20,000.

A company has been formed to bridge the Hudson River at Mechanicsville, N. Y., with a capital stock of \$120,000. George B. Perry is interested.

A bridge will be built over the Northern Central Railway, near Towson, Md., at a cost of \$8,000.

A scheme is on foot for bridging the Oconee River at Dublin, Geo.

At Leavenworth, Kan., a highway bridge, to cost \$500,000.

TAMPA, FLA., will probably have an iron bridge.

MACON, GEO.—Proposals will be received, until November 4, for the erection of a wooden bridge. For further particulars address W. G. Smith, Macon, Geo.

JACKSONVILLE, FLA.—See our Proposals for reference to a bridge over Hogan's Creek.

LEWISVILLE, O.—Address the County Commissioners in regard to a bridge to be built here.

CHICAGO, ILL.—The M. Lassic Bridge and Iron Works has been incorporated; capital stock, \$250,000. Messrs. Moritz Lassic, William G. Schniglaui, and Charles H. Hawkins, incorporators.

WACO, TEX.—Proposals will be received, until November 14, by the Commissioners' Court of Waco, Tex., for the erection of an iron bridge across the Brazos River. The bridge will be 560 feet long, 42 feet high, and 20 feet roadway, tubular iron piers, centre tubes not less than six feet, and end tubes not less than five feet in diameter; the centre span to be 240 feet, and the end spans 160 feet each. The bridge is to have a capacity of not less than 100 pounds to the square foot. For further particulars address the County Commissioners.

TRENTON, N. J., is to have a bridge. Address Commissioners.

RED CLOUD, NEB.—A bridge costing \$13,000 will be built by the County Commissioners.

PORTLAND, ORE.—The Columbia River Bridge Co. has been incorporated; capital stock, \$500,000. The incorporators are H. S. Rowe, M. C. George, R. L. Dunham, and others.

BRIDGE COMPANY.—Incorporated a few days since was the Louisville and Jeffersonville Bridge Company, of Louisville, Ky. Directors: Dennis Long, John F. Read, E. Fuller, and others.

STREET WORK AND PAVING.

RUTHERFORDTON, N. C., will make street improvements; money appropriated.

MOBILE, ALA.—City Council is taking steps to have a large amount of granite street paving done.

WASHINGTON, D. C.—The District Commissioners place in the estimate \$800,000 for street improvements to be made the coming year.

MILWAUKEE, WIS.—Contracts have been let for street work as follows:

John O'Neil, curbing Holton Street, 13 cents per lineal foot.

John Dobberson, grading Twenty-third Street, from Fond du Lac Avenue to Center Street, 15 cents per cubic yard.

Ed. Becker, paving gutters, 67 cents per square yard.

J. H. Kearner, curbing Twentieth Street, 50 cents per lineal foot. Resetting old curb ing, 13 cents per lineal foot.

TORONTO, ONT.—A report has passed the Committee of the Whole of City Council, providing for improvements on the Ravine Park Drives, at a cost of \$225,000.

SARATOGA, N. Y.—Village Engineer Cramer has presented to the Village Board an estimate of the cost of improving East Avenue, placing it at \$23,000.

DETROIT, MICH.—City Council has directed the Board of Public Works to proceed with the improvements of Linden Park.

LITTLE ROCK, ARK.—See our Proposals for reference to brick and concrete sidewalks.

ALTOONA, PA.—The Highway Committee is advertising for bids for macadamizing Green Avenue.

CINCINNATI, O.—C. H. Crane is the contractor for the improvement of Madisonville Pike Road.

MONTREAL, CAN.—About \$4,000 is appropriated for asphalt pavement, to be laid on St. James Street and Place D'Armes, and a contract has been awarded to William McDonald for a sewer in Conde Street, at \$7.75 per lineal yard.

BROOKLYN, DE.—DeKalb Avenue will be paved with granite blocks. Proposals will be received by the Commissioner of City Works until October 19; two sureties, \$8,000 each.

PITTSBURG, PA.—Carson Street, Sycamore Street, Bryant Street, Shiloh Street will be improved. Address E. M. Bigelow, City Engineer.

BOSTON.—It is ordered that Dillon Street be laid out, also Maynard Street. Address J. H. Jenkins, Clerk of Street Commissioners.

LOWELL, MASS.—Council has appropriated \$10,000 for street work.

NEW YORK CITY.—Engineer Greene submitted plans October 13 to the Dock Department for fixing the line of piers from Eighty-sixth Street, where the proposed \$6,000,000 extension street ends, to the Third Avenue Bridge.

RAILROADS, CANALS, ETC.

BLOOMFIELD, N. J.—The Orange Cross-town Railway Company has received permission from the Bloomfield Township Committee to lay tracks in the streets of Bloomfield. It is proposed to connect Bloomfield and Orange.

KNOXVILLE, TENN.—McDonald, Shea, Dunavant & Co. have the contract for building twenty miles of the Powell's Valley Railroad. Work will be begun at once.

PORTLAND, ME.—A committee of the directors of the Rockland, Rockport and Camden Railroad will meet the directors of the Knox and Lincoln to confer with regard to the construction of the railroad from Rockland to Rockport Village in Camden.

CHICAGO, ILL.—The Hoyt Railroad Track Crossing Company, of Chicago, has increased its capital stock from \$500,000 to \$1,000,000.

RENO, NEB.—A street-railroad will be built here. A party is now seeking for a fifty years' franchise from the city.

GALVESTON, TEX.—A. Bonzano, C. E., favors the plans for constructing a breakwater and improving the harbor.

CAMDEN, N. J.—A large engineering work is projected in the removal of Windmill and Smith's Islands, between this city and Philadelphia. We quote the *Philadelphia Express*:

"Last May the Harbor Commissioners requested their Advisory Board to 'examine and report concerning the physical relations of Smith's and Windmill Islands and the shoal thereto to the improvement of the harbor.' Then it was expected that by this time some report would have been made. Now it looks as though fully three months must elapse before the board will make a report to the Harbor Commissioners. Of course the resolution carries with it for consideration the entire removal of the two islands, together with the dredging of extensive shoals North and South. An estimate of the cost reaches \$3,000,000."

MILWAUKEE, WIS.—The Chicago, Milwaukee and St. Paul Railway Company let the contract, October 6, to Shepard & Co., of St. Paul, for building ten miles of road north-west from Goodrich's Mills, a point about four miles north-west of Mather, a station on the Valley Division.

The St. Paul Railroad Company has been asked to pave Hill Street, from Sixth to Eighth Street.

WABASHA, MINN.—At the election October 5 to vote upon the question of issuing \$30,000 bonds for ferry purposes and other local improvements, the proposition was carried by a majority of 160.

NASHUA, N. H.—William H. Ward has been awarded the contract for repairing and strengthening the canal of the Nashua Manufacturing Company.

RAILROAD WORK.—In our Proposal Columns will be found a reference to extensive works to be undertaken by the Rome, Geo., and Columbus Railroad Company.

LEAVENWORTH, KAN.—The Leavenworth, Northern and Southern Railroad has reached this city and will be extended to Denver.

CLEARFIELD, PA.—The preliminary survey, for a railroad connecting the Beech Creek and the Tyrone and Clearfield, has been completed. The elevation to climb from this point is about 1,000 feet and the length of the road will be twenty-eight miles. The enterprise is controlled by Clearfield and Dubois capitalists.

OTTAWA, ONT.—A party of Government engineers are engaged in studying the engineering features of the proposed new route of Sault Ste. Marie Canal. The time for receiving tenders for the work expires in January.

MERIDIAN, MISS.—The contract for grading the Warrior Coal Fields Railroad from Meridian, Miss., to Gainesville, Ala., a distance of 56 miles, has been awarded to Messrs. Dunn Bros., of Birmingham, Ala.

MACKINAC, MICH.—Steps are being taken to build an electric-railway around Mackinac Island.

BIDS OPENED.

PAWNEE CITY, NEB.—The following bids for constructing the water-works at Pawnee City, Neb., were received by the Mayor and Council, October 7, 1887: Charles Schroder, Columbus, Neb., for the whole works (except wells), \$25,125. H. F. Cook & Son, Omaha, Neb., for two tubular wells, \$2,500.

GRAND RAPIDS, MICH.—The following bids for constructing the hospital for contagious diseases were received by the Board of Public Works, September 24, 1887:

Joel Collins, city, \$3,535.
J. D. Boland, city, \$4,200.
John Olson, city, \$4,220.
James Curtis, city, \$5,375. Contract awarded to Joel Collins at \$3,535, October 1, 1887.

LOS ANGELES, CAL.—The following bids for building the Court-House were received by Corbett, Essen & Cuthbertson, Architects, September 20. The specifications referred to two methods of building. Proposition No. 1 will probably be adopted relating to granite basement, superstructure of pressed brick, sandstone and terra cotta trimmings:

F. E. Green, Los Angeles, proposition No. 1, \$387,200; proposition No. 2, \$430,000.
Charles F. Trill, San Francisco, No. 1, \$385,750; No. 2, \$422,275.
David Perry, San Francisco, No. 1, \$380,050; No. 2, \$417,500.
W. E. Stratton, Los Angeles, No. 1, \$380,000; No. 2, \$416,000.
A. F. Mackay, Los Angeles, No. 1, \$381,000; No. 2, \$415,000.
William Hanbon, Los Angeles, No. 1, \$386,000; No. 2, \$421,600.
California Bridge Co., San Francisco, No. 1, \$390,000; No. 2, \$422,000.
William Fletcher, Los Angeles, No. 1, \$385,000; No. 2, \$419,000.
O. E. Brady, San Francisco, No. 1, \$375,000; No. 2, \$410,000.
Contract awarded to O. E. Brady.

CHAUTAUQUA LAKE, N. Y.—The contract for dredging the outlet of Chautauqua Lake has been awarded to Willard Johnson, of Fulton, N. Y., at \$15¢ per cubic yard.

ROCHESTER, N. Y.—The following bids for trenching and laying water pipe in Group No. 128, have been received by the Executive Board:

BIDDERS.	
Andrew E. Hyde.....	\$0.18
William Dyer.....	.20
George Chambers..	.26
N. L. Beyer.....	.20
	4,970 lin. ft. of trenching.
	540 lin. ft. of 10-in. cast-iron pipe.
	1,950 lin. ft. of 8-in. cast-iron pipe.
	2,260 lin. ft. of 6-in. cast-iron pipe.
	185 lin. ft. of 4-in. cast-iron pipe.
	10 additional 10-in. lead joints, over 5.
	10 additional 8-in. lead joints, over 5.
	10 additional 6-in. lead joints, over 5.
	Total.
	\$1,548.15
	1,690.00
	1,950.25
	2,133.00

Awarded to A. E. Hyde.

NEW YORK CITY.—Bids for constructing an engine-house for Company 54 were opened as follows, October 12, by the Fire Department: Mahony Bros., \$15,750; George H. Christie, \$18,245; James H. Brady, \$17,900. All the bidders are New York parties.

NORFOLK, VA.—H. E. Culpepper, of Norfolk, Va., was the lowest bidder at \$2,300 for repairing the St. Helena wharf.

CLEVELAND, O.—The following bids for cast-iron cylinders, for Lake Tunnel, were received by Cleveland Water-Works October 6 (No. of cylinders, 17; total weight, 150 tons):

Bowler & Co., Cleveland, 3½¢ per pound.
Maher & Brayton, Cleveland, 3½¢ per pound.

Harford Dredging Co., 40 South Street, New York,	4.50	
M. K. Pidgeon, New York,	4.50	
	4.50	For remaining 4,100 feet of channel.

* For all material that can be dredged without blasting.
† Rock-work not included.

GOVERNOR'S ISLAND, N. Y.—The following bids for furnishing and laying water-pipe between Governor's Island and Brooklyn, N. Y., were received by Captain J. H. Lord, Assistant Quartermaster, October 7:
John F. Ward, Jersey City, Hudson Co., N. J., \$12,400; accepted.

SYNOPSIS of bids for ventilating and steam-heating at Concord, N. H., opened by the Supervising Architect October 10: L. E. Milles, \$6,170, Walworth radiator; Bartlett, Hayward & Co., \$7,125, 1' vertical, own.

Same for Leavenworth, Kan.—Bartlett, Hayward & Co., \$14,800, 1' vertical, own radiator, Sturtevant fan; James Foley, \$9,975.

Same for Hannibal, Mo.—Bartlett, Hayward & Co., \$5,180, 1' vertical, own radiator; Herbert L. Rose, \$4,067.65, Haxton's; L. Pope & Co., \$5,790, Crane's, Walworth's, and Gold's.

OMAHA, NEB.—The following bids for superstructure of new City Hall building, Omaha, Neb., were received and opened by Board of Public Works, Omaha, Neb., October 7:

Sholes & Co., Omaha, Neb., \$234,490; Brennan Bros., Omaha, Neb., \$259,640; Rice & Bassett, Omaha, Neb., \$261,473.82; James Griffith, Omaha, Neb., \$285,000; Cunningham & Ryan, Omaha, Neb., \$293,675; James Fox & Co., Omaha, Neb., \$360,640.

Contract will not be awarded until Supervising Architect Myers arrives from the East, which will be some time this week.

WASHINGTON, D. C., Navy Department.—There was but one bid for the dredging at Coaster's Harbor Island, R. I., that of Mr. C. M. Anthony, of Fall River, Mass., whose offer was forty cents per cubic yard; but being quite informal, not on required form, nor accompanied by guaranty required by law, it was not considered.

SYNOPSIS of bids for materials, tools, and labor for plumbing for Court-House and Post-Office, Waco, Tex., opened by the Supervising Architect October 10 (first opened September 20 and rejected):

May & Wainwright, entire work, \$4,518.14; base ment only, \$2,032.04; basement and second story, \$3,744.20; basement and third story, \$3,705.80.
Crook, Horner & Co., entire work, \$5,370.05; base ment only, \$3,866.21; basement and second story, \$4,618.14; basement and third story, \$4,618.14.
P. Nacey, entire work, \$4,739; basement only, \$1,511.31; basement and second story, \$2,732.67; basement and third story, \$2,688.66.
Marion & Co., entire work, \$3,911.60; basement only, \$2,608.05; basement and second story, \$3,260.10; basement and third story, \$3,260.10.

NORFOLK, VA.—The contract for repairing the roofs of the Naval Hospital has been awarded to Mr. John Massingham of this city. The following were the bids: W. H. Barnard & Co., Norfolk, \$750; J. V. Kierman, Norfolk, \$590; J. E. Wright, Norfolk, \$560; B. A. Richardson, Norfolk, \$470; John Massingham, Portsmouth, \$380.

DAVID'S ISLAND, N. Y. H., October 7.—The following bids for brick sidewalk were received by Captain George H. Cook, A. Q. M., October 6:
Fallon & Sheehan, New Rochelle, N. Y., 90¢ per lineal foot; Richard Calrow, Brooklyn, N. Y., \$1.13 per lineal foot; Murphy & Gillespie, New York, \$1.105 for the entire work. The contract was awarded to Fallon & Sheehan, of New Rochelle, at 90¢ per foot for 1,055 feet.

WASHINGTON, D. C.—The new set of bids on plumbing for the Waco, Tex., public building were opened by the Supervising Architect, October 10, as follows: May & Wainwright, Galveston, whole job, \$4,518; in basement, \$2,032; basement and second story, \$3,744; basement and third story, \$3,705; time, 100 days.

Crook, Horner & Co., Baltimore, whole job, \$5,370; in basement, \$3,866; basement and second story, \$4,618; basement and third story, \$4,618; time, ninety days.

P. Nacey, Chicago, whole job, \$4,939; in basement, \$1,512; basement and second story, \$2,732; basement and third story, \$2,688; time, sixty days.

Manion & Co., New Orleans, whole job, \$3,911; in basement, \$2,608; basement and second story, \$3,260; basement and third story, \$3,260; time, sixty days.

ABSTRACT of bids for dredging in South River, N. J., opened at the U. S. Engineer Office, Army Building, New York City, at 12 o'clock m., on September 22, under circular dated September 12:

P. Sanford Ross, 113 Hudson Street, Jersey City, N. J., 2 1/2 cents per cubic yard measured in scow.

M. K. Pidgeon, 60 South Street, New York City, 32 cents.

W. H. Beard, 302 Hamilton Avenue, Brooklyn, N. Y., 35 cents.

James M. Spint, 330 Third Street, Jersey City, N. J., 34 cents.

Hartford Dredging Company, Hartford, Conn., 29 cents.

Richard M. Payn, 61 Quay Street, Albany, N. Y., 29 1/2 cents.

CHelsea, MASS.—The only bid opened by the Supervising Architect September 30 for repairs of heating and ventilating apparatus of Marine Hospital at Chelsea, Mass., was that of the Walworth Manufacturing Company, of Boston, \$18,797.

PROPOSALS.

(Continued from page 544.)

NEW FLOORS, etc., at Bellevue Hospital.—Bids or estimates will be received at the office of the Department of Public Charities and Correction, No. 66 Third Avenue, in the city of New York, until 9:30 o'clock a. m. of Tuesday, October 18.

COUNTY JAIL.—Proposals will be received by the County Commissioners of Duval County, Fla., until December 5, for the building of an addition to the County Jail in plan, 44 feet by 58 feet, to contain 42 cells. Plans can be seen and specifications procured at the office of R. N. Ellis, County Engineer, Bostwick's Block, Jacksonville, Fla. Separate bids will be received for the iron-work. Endorse "Bids for County Jail," and direct to Captain W. E. Buckman, County Clerk, Jacksonville.

STEAM-HEATING apparatus for the Seventh Precinct, Brooklyn.—Proposals will be received until the 18th day of October for furnishing steam-heating apparatus for the Seventh Precinct Police Station-House, corner of Greenpoint Avenue and Manhattan Avenue. Thomas Carroll, Commissioner of the Department of Police.

ROAD-WORK.—Proposals will be received by the clerk of the village of Mt. Airy, O., until November 5, for the improvement of the Cary Road, by grading, macadamizing and graveling the same, and constructing drains, culverts and bridges, in accordance with plans and specifications on file with A. A. Brasher, Engineer. E. George Jacobs, Corporation Clerk, Mt. Airy, O.

RETAINING WALL.—Proposals will be received until October 18, to furnish the materials and do the work on a retaining wall on the Falls Road, between Maryland and North Avenues, Baltimore, Md. A. E. Smyrk, City Commissioner, Baltimore, Md.

BRICK SIDEWALKS.—The Commissioners of Improvement District No. 4, want proposals until October 17, for laying brick sidewalks in the district. Address R. A. Edgerton, Room 16, Bowman Block, Little Rock, Ark.

LIGHTHOUSE-WORK.—Proposals will be received until the 22d day of October for furnishing the materials and labor for the construction of the metal-work for the Castle Hill Lighthouse, Narragansett Bay, Rhode Island. Major D. P. Heap, U. S. Engineers, Tompkinsville, S. I.

BRIDGE.—Proposals for a bridge over Hogan's Creek at the crossing of the same by Duval Street Bridge, Jacksonville, Fla., to be thirty feet wide, with approaches twelve feet wide on each side of bridge; also for building a roadway 368 feet, and twenty feet on East Jacksonville side across marsh. Total length of bridge including roadway about 430 feet. W. B. Watson, Room 6, Ely Block, Jacksonville, Fla.

LEVEE-WORK.—Proposals will be received, until October 25, for levee work on the White River front to the approximate amount of 400,000 cubic yards. Smith S. Leach, Captain of Engineers, Memphis, Tenn.

BUILDING.—Proposals will be received, until November 4, for building Court-House. Address John F. Sharp, Clerk Board of Supervisors, Louisville, Miss.

PROPOSALS will be received by the Commissioners of Montgomery County, Pa., at their office, in Norristown, up to 17th day of October, for the masonry and repairing of two bridges, one over Five Mile Run, the other over Stony Creek on Germantown pike in the township of Norristown. James Burnett, Hiram Burdian, Thomas McCully, Commissioners.

PUMPING ENGINES.—Proposals will be received at the City Engineer's office, Minneapolis, Minn., until November 17, for the construction, delivery, and erection of two horizontal compound condensing pumping engines, with a daily capacity of fifteen million gallons each; also for building and erecting a pumping station near Shingle Creek; also for furnishing about 12,000 lineal feet of 36-inch cast-iron water-pipe. Specifications for pumping-engines and cast-iron pipe and plans and specifications for the building, can be seen at this office. Parties bidding can state a price for any part or the whole of the work, but a separate proposal, properly endorsed, must be submitted for each of the three (3) classes of work advertised for. The right to reject any or all proposals is reserved. Andrew Rinker, City Engineer.

NEW WELL.—Proposals will be received until October 27, for furnishing materials and constructing a well and appurtenances. The well consists, in general, of a caisson about 35 feet high and 25 feet in diameter, with iron shoe, dome, 24-inch suction-pipe and fittings, etc. The foot of the caisson is to be sunk about 35 feet below ground line. Chauncey Strong, City Clerk, Kalamazoo, Mich.

PROPOSALS.

IMPROVING BUILDING.—Superintendent's Lodge at Natchez, Miss., National Cemetery. Until October 20. Address Major E. B. Kirk, U. S. A., Gate City Bank Building, Atlanta, Geo.

BRIDGES.—Proposals will be received until October 15, for the construction of three bridges over the Natchez and Yakima Rivers. Address W. F. Prosser, North Yakima, Wash. T.

BRIDGE.—Proposals are invited for the erection of a 150-foot span iron bridge. For further particulars address William P. Kelly, San Angelo, Tex.

WATER-WORKS.—Proposals will be received for the construction of water-works in the town of St. Andrews, N. B. The estimated quantity of pipe is 4 miles, with hydrants, etc. Full particulars on application to T. McGrath.

THE Board of Supervisors of Winston County, Miss., will receive bids on November 7 for the building of a new court-house at Louisville, Miss. Plans and specifications are on file in the Chancery Clerk's office. John F. Sharp, Clerk Board of Supervisors, Louisville, Miss.

PILE FOUNDATION.—Proposals will be received until October 19, for constructing about 3,500 lineal feet of pile and timber foundation for Section V. of Boulevard sewer, New Haven, Conn. Albert B. Hill, City Engineer. City Engineer's Office, 17 City Hall, New Haven, Conn.

STEAM-HEATING apparatus for the Sixth Precinct.—Proposals will be received until Tuesday, the 18th day of October, for furnishing steam-heating apparatus for the Sixth Precinct Police Station House, corner of Bushwick Avenue and Stagg Street, Brooklyn, E. D. Thomas Carroll, Commissioner of the Department of Police and Excise, Brooklyn, N. Y.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1887, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 16.

NUMBER 21.

PUBLISHED EVERY SATURDAY.

NEW YORK, OCTOBER 22, 1887.

LONDON, NOVEMBER 5, 1887.

SINGLE COPIES, TEN CENTS.
Subscription, \$4.00 per year in advance, post paid. } IN AMERICA
SINGLE COPIES, SIXPENCE.
Subscription, 20s. per annum in advance, post paid. } IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, conducted by HENRY C. MEYER, is published every Saturday at 82 & 84 Fulton Street, New York. Its opinions upon all technical subjects are either prepared or revised by specialists.

TERMS, \$4 PER YEAR, IN ADVANCE.

Postage Paid.

OFFICE IN GREAT BRITAIN,
98 & 92 FLEET ST., LONDON.

TERMS, 20s. PER YEAR, IN ADVANCE. Postage Paid.
SINGLE COPIES, SIXPENCE.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York), and crossed ——— & Co.

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 20, Leipzig, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, \$5; China, Japan, Sandwich Islands, Mexico and Cuba, \$5; South America, \$5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us promptly of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

STATE ENGINEER AND SECRETARY OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS.

MR. JOHN BOGART, the well-known Secretary of the American Society of Civil Engineers, has finally consented to accept the nomination for State Engineer unanimously tendered him by the Democratic State Convention. We believe he will be elected, and that the State will secure the services of a good engineer and a gentleman.

The gratification, however, which all his friends and supporters will feel at such a result must, in the case of his fellow members of the society, be largely tempered with regret at the thought that the society will, in all probability, lose his services as secretary, since it must be apparent that its interests will require more time than the probable engagements of Mr. Bogart would permit him to give. He has served the society well during many years, and has in that time seen it grow in influence and prosperity, which must be a source of great satisfaction to him, and we hope he will long continue to be a member of its board of direction.

The present movement looking to a change in the by-laws of the society with a view of increasing its popularity with the members of the profession, while at the same time relaxing nothing from its high standard of qualifications for membership, indicates a proper appreciation of the field the society should occupy. Much will depend in the future, as it has in the past, on the character and capacity of its most active executive officer—namely, its secretary. With him must originate many things that will increase the usefulness of the society to its members and thereby add to its influence and popularity.

The time has now come when it is necessary that the man who holds this office should have no other professional engagements. The salary should be increased, so that this may be practicable and that the proper man may be secured—one whose whole time and efforts can be devoted to promoting the best interests of the society.

To indicate our idea of the kind of man who could meet the requirements of the case we would name Captain Edgar B. Van Winkle, a member of the society, and now the efficient Recorder of the New York Commandery of the Military Order of the Loyal Legion. In thus naming him we owe it to him to say that we do it without his knowledge or consent, and we have no idea whether he would accept the office even if it were offered to him. Yet in our opinion he typifies the kind of man the American Society of Civil Engineers should have for its secretary, should Mr. Bogart be elected State Engineer.

EDUCATION IN ENGINEERING.

AN address by Professor Osborne Reynolds before the section of Mechanical Science of the British Association deals with this subject. One of the thoughts he expresses is "the smallness in number of recorded attempts to decide the broader questions in engineering by systematic experiments," notwithstanding the great results which, in the long run, have followed as an effect. This becomes a plea for the establishment of engineering laboratories as an adjunct of all institutions for teaching of practical science. These laboratories and the educational workshops that have been introduced undoubtedly serve an

admirable purpose in giving students a trained eye, a mechanical touch, and sound ideas respecting materials.

We cannot but feel, however, that the great mass of engineers, from the nature of the case, become practitioners, rather than original investigators. Time will not allow them to make exhaustive examinations in any direction, and even if it did, the funds that are requisite are not forthcoming. The man who is to make a scientific investigation needs to have nothing else to interfere with his thoughts. If he would see deeper than others have, he must become so imbued with the subject that he cannot think of other things if he would. When he is in this frame, no phenomena, however small, escape him, and the whole mass of observations goes through a process of mental digestion and sifting, from which the truth comes forth as a new creation for the use of the man of action.

We believe in the manual education of engineers as a corrective of the purely theoretical. We believe, also, that there is room for men of intellect and leisure to go on increasing our stock of knowledge from which the practicing engineers must draw.

THE SPECIFIC GERM OF TYPHOID FEVER.

THAT typhoid fever is due to a particular kind of bacillus has for several years been considered extremely probable by those who have investigated the subject. Mr. Desmond Fitz Gerald, a well-known engineer of Boston, recently wrote a letter to the *Boston Advertiser*, from Paris, in which he gives an account of recent investigations on this subject made by Drs. Chantemesse and Widal, and declares, as the result of his observations, that he now has no doubt that the disease may be communicated by means of bacilli carried in drinking-water. The water-supply of Paris comes from several sources.

"Of these the Vanne is undoubtedly an excellent water, and there is no danger to be apprehended from its use. Unfortunately, almost every year the water from this source fails to be sufficient in quantity, and then the water from the Seine and other polluted sources is turned into certain quarters of the city. It has been noticed for several years that when this takes place the number of typhoid cases immediately increases. Drs. Chantemesse and Widal have been able to show that these polluted waters contain the bacilli of typhoid fever.

"In 1882 there were 3,352 deaths in Paris from typhoid. In the first six months of the year there were 965 deaths. In August the deaths from this cause reached 325, in September 275, and in October the number suddenly increased to 860. The number diminished again rapidly in November and December. During this time much of the waters of the Seine, the Ourcq, and the Marne were distributed for drinking purposes, and in the 11th and 12th arrondissements there was scarcely any other water in August, September, and October excepting that of the Seine. Among the firemen of the city it was found that there were very few deaths among those who drank the Vanne, while there were many cases among those who drank from the sewage-charged waters. Dr. Chantemesse told me that he had been able to propagate colonies of the typhoid bacilli in the water of the Seine for more than three months, and that they lost nothing of their activity at the end of that time.

"In nineteen cases out of twenty of persons suffering from typhoid fever Dr. Chantemesse told me he had never

failed to find the typhoid bacilli in certain portions of the body. The moment convalescence begins the bacillus disappears.

"In the middle of the summer of 1886 a family composed of seven persons inhabited a house in the Rue des Rasselins, Menilmontant. Five of them were attacked with typhoid fever and sent to the hospital. They had been drinking the water from a public fountain in their neighborhood, in which Dr. Chantemesse found the living bacillus of the typhoid. In an epidemic at Pierrefonds the water of the wells was found to contain the same bacillus. At Clermont-Ferrand, a city in the Auvergne Mountains and capital of the Puy de Dome, there was an epidemic a short time since of typhoid. The connection between the cases in that city and the water-supply was traced by Dr. Chantemesse. The following experiment was made to show the persistence of the typhoid bacillus: A flask was filled with water, and in the bottom of the flask a little earth was introduced. Some colonies of the bacillus were cultivated in the water. At the end of two months the water, having failed to show the presence of specific germs or spores, was decanted gently, and ordinary water put into the flask on top of the sand and earth remaining in the flask. The next day this water was found charged with the typhoid bacillus. This experiment shows the importance of a most thorough cleaning

cific germ of typhoid fever which flourishes in water polluted by sewage. It is probable that this germ soon loses its vitality in comparatively pure water, especially if this is well aerated. It is also easy to understand that the absence of typhoid fever in a community is no proof that its water-supply is not polluted; it may simply indicate that the specific germ has not yet been introduced, although the conditions are favorable for its development, and it is to be feared that this is the case in many of our American towns and villages.

BUILDING INSPECTION THAT DOES NOT INSPECT.

INSPECTION that does not inspect, or, if it does, fails to report, alone made possible the shocking disaster in the Harlem school building elsewhere referred to, and it is well that the delinquent inspector should be promptly and properly punished, but the fault after all lies as much

conscience and convenience and usually far exceeding anything contemplated by the authors of the unreasonable requirement.

If the Fire Commissioners have the authority and the means to employ a sufficient number of additional inspectors they should do so at once, and if not they should immediately make their wants known in the proper quarter. They cannot otherwise escape a very grave responsibility, and as it is they may congratulate themselves that matters are no worse, and that the accident was not delayed until the building was filled with children.

THE RETORT-HOUSE ROOF.

THERE is little for modern builders to learn from the fall of the retort-house roof, described and illustrated on another page, for nobody would think of using flat iron for rafters nowadays; but we believe there are not a few of such roofs still in use, and it behooves the users

RESIDENCE AT WORCESTER, MASS.—W. R. EMERSON, ARCHITECT.

of the bottom and sides of reservoirs, aqueducts, etc., which have been exposed to the bacillus, and it also applies to the interior surfaces of pipes.

"The village of Monts is divided into two portions, one on a hill several hundred feet above the other. On the higher portion, in 1878, two cases of typhoid fever appeared among some children. Their linen was washed in the water from which the lower portion of the village took its supply. In a short time an epidemic broke out in this portion of the village, and it was arrested after the water-supply was abandoned. This was rather a striking case, for out of thirty-three inhabitants of the lower portion fourteen were attacked, and those only escaped who did not use the public water. Other cases might be cited where the presence of an epidemic of typhoid fever has been found to coincide with the presence of the specific germ in the drinking-water. The principal value of the recent progress made in the study of the subject consists in the complete identification of a specific form of bacteria, which has its own individual peculiarities, and which is found always in the body of the typhoid patient. I have seen in the laboratories at Paris all the various stages of growth of this typhoid bacillus, from the soft, round and almost colorless spores, to the active young creature, squirming around by the thousand; in fact, I was offered a small colony of them if I wished to transport them to Boston for cultivation."

It will be seen that Mr. Fitz Geraid gives good reasons for his belief in the existence of a spe-

with the system as with the individual. The statement in the report of the Superintendent of the Bureau of Inspection of Buildings to the effect that each inspector is required to examine and report on an average of over 110 buildings and alterations each day, affords a text from which a very wholesome sermon could be preached to the Board of Fire Commissioners of this city. It is manifestly impossible for the inspectors to comply with this requirement, and practically they are not expected to do so, but any regulation which has to be continually ignored and which requires a pretence of doing what everybody knows cannot be done is utterly demoralizing.

Duty and ability are always commensurate, and requirement should be also. When all is required of a man that he can fairly do and he is held strictly accountable for its full performance, the effect is most salutary, but to require more than that means either tyranny or connivance at neglect and disobedience; and when neglect and disobedience are once tolerated their amount is on a sliding scale, measured only by the individual

to see to them promptly. A wooden joist, or, if exposed to heat, an angle-iron bolted or clamped alongside of each flat rafter, would probably prevent such a collapse as occurred at the works of the Consolidated Gas Company, although if there should be any braces of round iron in the truss they also should receive attention.

OUR ARCHITECTURAL ILLUSTRATIONS.

A HALL IN E. W. ANTHONY'S RESIDENCE, LONGWOOD, MASS.—E. A. P. NEWCOMB, ARCHITECT.

RESIDENCE AT WORCESTER, MASS.—W. R. EMERSON, ARCHITECT.

THE subject of our vignette illustration this week shows a residence at Worcester, Mass.

The first story is field-stone and walls and roof shingled and stained. The interior of the first story is finished in oak, ash, and cherry, and the second story stained pine. W. R. Emerson, of 5 Pemberton Square, Boston, Mass., was the architect.

THE KANAWHA RIVER IMPROVEMENT.

(Concluded from page 501, Vol. XIV.)

WE give now the cuts promised in our previous article. Figure 1 gives a good idea of the appearance of dam No. 6 when full, taken October 9, 1886, soon after completion and before the *debris* of the coffer-dam had been removed from below the weir. The view is taken from the abutment at the end of the weir looking toward the lock. It shows clearly the lock, the navigation pass next adjacent, and the weir; the lengths *across the river* being respectively about 90 feet, (the lock chamber is 55 feet wide in the clear) 250 feet, and 310 feet. Figure 2 is a section through the weir, and Fig. 3 a section through the Navigation Pass. This latter shows quite clearly the way in which the wickets are held in position. It shows also the axle at the lower end of the bridge trestle, about which it revolves sidewise when lowered down to give a clear waterway; also the anchoring of the sills, etc. It will be noticed that the sill of the weir is three feet above low water, and that of the Navigation Pass $2\frac{1}{2}$ feet below the same. It will be noted that the sill in the weir against which the wickets rest is of cast iron, and it is considered a great improvement over the use of timber. Figure 4 shows a view next to the lock in a section of the coffer-dam for the construction of Navigation Pass. The foundations of the pass are here shown nearly completed; one wicket and one bridge trestle are standing, also several of the horses and props ready for the wickets. It also shows a number of the slides and hurters in position.

Figure 5 is a nearer view of part of Fig. 4. It shows one of the wickets balanced on its prop, also other horses and props ready for the wickets, and one of the props, etc., down on the bed, as it is when the waterway is left clear. In the same manner the trestles also are lowered sidewise flat on the bottom in times of freshets or ice disturbance.

Figure No. 6 gives exact views of three forms of hurter now in use. The original Chanoine hurters were introduced on dams 4 and 5 of the great Kanawha improvement in accordance with the best European practice when these dams were planned in 1875. In connection with them the tripping-bar is used for lowering the dam.

The Pasquean hurter is a modification, as appears by the drawings, of the Chanoine hurter. This improvement was made by Pasquean, a French engineer of the Ponts et Chaussées, and applied by him on the La Mulatière dam at Lyons in a pass 340 feet wide. The La Mulatière dam was completed in 1881. Some of the Pasquean hurters have been introduced on the Great Kanawha dams. The first were tried at Dam No. 5 in 1881. This dam is now operated partly with the improved hurters and partly with the Chanoine hurters and tripping-bar.

Dam No. 4 (completed in 1880) is still operated, as built, with the tripping-bar and Chanoine hurters. Dam No. 6, finished last year, has all Pasquean hurters and no bars.

The operation or use of the hurters will be readily understood from the drawings. When the dam is erect the end of each wicket prop rests against the face or shoulder (S) of its hurter.

With the *Chanoine hurter* it is *pulled* to one side by the bar, when the wicket, being free to fall, the end of the prop runs down the descending channel of hurter and slides to its place. In raising the wicket, the end of the prop is guided by the groove (P Q) and drops in its place against the shoulder S.

With the Pasquean or "stepped" hurter, the wicket is lowered by pulling it bodily up stream from the bridge. This, of course, draws the end of the prop away from the shoulder up stream until it drops from the step into the descending channel. The end of the prop is then guided to its place, both in lowering and raising the wicket, precisely as with the Chanoine hurter.

Pasquean's hurters have been modified for use on the Great Kanawha, as shown by the drawings, by the introduction of a block (B) on top of the step. This block causes the prop to drop from the step by a short and defined movement of the wicket, and saves considerable time in lowering the dam. The hurters have also been

improved on the Kanawha by widening the throat at X, experience at dams 4 and 5 proving that stones, etc., were apt to get lodged in the wedge-shaped throat of the old Chanoine and Pasquean forms and stop the prop and prevent the wicket from falling.

The advantages of the Pasquean hurter over the tripping-bars are important. The greatest advantage, as developed by practice on the Great Kanawha, is in *raising the dam*. With the tripping-bars some time is always required to clear the bars and gearing before the dam can be raised. This is avoided with the stepped hurters, and considerable time and labor of the lock hands saved. The Pasquean improvement is also simpler in construction and cheaper than the tripping-bars. The difference in the cost, as applied to one of the Great Kanawha navigation passes, is estimated at about \$2,000. This is on the basis of stronger and better bars and gearing than were used at dams 4 and 5, as the tripping apparatus at both of these first works built have proved too light. The dams can be *lowered* quicker and easier with the tripping-bars than with the Pasquean hurters. With the bars several wickets are thrown at once by gearing from the lock and pier-walls, while with the stepped hurters only one wicket is lowered at a time from the bridge.

The advantages, all considered, of the Pasquean hurters are admitted by the Government engineers connected with the Kanawha improvement, and have been fully acknowledged in their published reports, but Colonel Craighill, the officer in charge, considers these advantages not sufficient to justify paying the high royalty now demanded for the patent, and he thinks it probable that the stepped hurters will not be used at No. 7, the next movable dam to be built.

We insert the following paragraph from the *Kanawha Gazette* respecting the first movable dams in America:

"The great advantages of movable dams have long been recognized in Europe. In 1878 there were 124 movable dams in operation in France alone. The Great Kanawha had the honor of possessing the first movable dam in America.

"Dams Nos. 4 and 5 (the latter located at Brownstown, nine miles above Charleston, the other at Cabin Creek, six miles farther up), were completed in July, 1880, and have been in successful operation ever since. Dams 4 and 5 are both of the Chanoine type (the Davis Island Dam on the Ohio below Pittsburg, completed in 1885, is the same pattern), and although at Dam No. 6 a great many improvements have been made in construction and details, the

general principles of all three of the Kanawha movable dams are about the same. They are practically the same, too, as regards width of navigation pass and dimensions of the pass wickets. The pass wickets at No. 6, as before stated, are 13 feet 5½ inches long; those at Dams 4 and 5 are 13 feet 10 inches long. The Davis Island wickets are 13 feet long. The Great Kanawha wickets, with the exception of one dam in France, are thought to be the largest ever constructed."

The contrast of the broad, deep, placid pools, now seen on the Kanawha, giving entire safety to the vessels using them, with the tortuous, shallow stream, and the swift currents, before the improvement was made, is a very marked one; and what has been done here can be done in hundreds of other places in our country to the greatly increased development of its resources and the great benefit of trade in the vicinity of the improvements.

The names of the engineers and others identified with this work were given in the former article.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

No. XXIII.

(Continued from page 518.)

THE TUBE RIVETING MACHINES AT THE FORTH BRIDGE.

[Prepared for THE ENGINEERING & BUILDING RECORD by E. W. Moir.]

THE main steel piers of the South Bridge cantilevers are composed of four braced steel tubes, twelve feet in diameter, having each ten plates in their circumference, with double-covered butt-joints at their ends and lap-joints with the adjoining plates on their sides. At the lapping of the plates on the inside of the tube are ten beams of fourteen sections (see Fig. 2), each formed of a tee and two angles, the head of the tee being held by the rivets passing through the lap-joints. As there are 1,600 rivets in each length of sixteen feet of the tubes, which are 350 feet long. Mr. Arroll, the contractor, designed a special hydraulic riveter to do the work. Figure 1 is a vertical section of one of the tubes, showing the riveter in place. Figure 2 is a sectional plan. G and G' are two heavy steel circular rings, spaced twenty feet apart, and are kept at their correct distance by angle-iron framing, which, when covered with small-mesh wire netting, makes a complete cage from which nothing can fall.

The rings are kept at their required distance from the tube by hard wood wedges driven in opposite the stiffening H-beams. R is the vertical riveting girder, which is held to the outer flange of the circular rings by cast-steel clips, but can be moved to any circumferential position by means of the small hydraulic jacks J. On the face of the girder, held in a cast-steel saddle, is the riveting cylinder, to which there is also attached a small platform for holding the men whose business it is to attend to the closing of the points of the rivets.

The saddle with its stage and cylinder can be raised or lowered to any height by means of the small hydraulic jack S, the cock controlling which is within easy reach of the men in the cage. Holes are provided in the face of the riveting girder, as well as round the circumference of the ring, against pins passed through which the ram is made to push when it is desired either to raise the cylinder or alter the radial position of the girder R. We have then on the outside of the tube a vertical girder movable to any position round the circumference of the tube carrying a cylinder which is capable of putting a pressure of forty tons on the point of any rivet on a length of seventeen feet. The inside girder does not travel bodily, but is made to rotate by suitable gearing within reach of the men on the small internal lifting platform, on trunnions at its ends. (See Fig. 1.) These trunnions are held in a central position by angle framing at the upper and lower ends of the girder (F, Figs. 1 and 2), which are wedged to the faces of the longitudinal stiffening-beams of the tubes, and rest upon the small movable brackets B, Fig. 1. The cylinder is in this case far from its work, but is provided with snap L with a movable cranked end so made to get in at the backs of the angles on the H-beams. (See Fig. 2.) The cylinder-platform and men are raised and lowered by a small hydraulic jack S, Fig. 1, in the same way as on the outer riveting girder. We have then inside a cylinder of the same power as that without, which can be brought to bear on the head of any rivet in a length of seventeen feet of the tube. The whole

machine is suspended with platform above and is raised with it in sixteen feet stages, or sufficient to put on one course of plates. The water is admitted to both cylinders at once from one cock Q, but is delayed by a suitable valve from entering the outer cylinder until the rivet is well pushed into the hole from within. The rivets are heated in a specially designed oil-furnace just above the machine inside the tube, and have been put in at the rate of over 800 per day by unskilled laborers. The pressure used is that which is supplied throughout the works—namely, 1,000 pounds per square inch, carried to the various moving parts by flexible rubber hose.

[Other articles describing the plant used in the erection of this notable structure are being prepared for publication in this journal.]

SOME DETAILS OF WATER-WORKS CONSTRUCTION.

No. III.

BY WILLIAM R. BILLINGS, C. E.

Superintendent of Water-Works, Taunton, Mass.

(Continued from page 553.)

TRENCHING.

A TRENCH which is troublesome on account of caving grows worse the longer it is open; if, therefore, the trenching-gang is a good distance ahead of the pipe-layers, and water and quicksand are found within two or three feet of the surface, it is wise to send the diggers ahead on to dry ground, or make some other arrangement, so that the last two or three feet in depth of the wet trench will not be opened until pipe can be dropped into it. When caving occurs in wet, heavy ground some warning of the impending trouble is given by cracks in the surface, running nearly parallel to the side of the trench; but in sandy gravel the drop comes without warning and men may be seriously injured. In any case the tendency to caving is increased by the weight of the excavated material piled up on one edge of the trench, and if circumstances will permit it is well to keep men on the bank to shovel back the material as fast as it is thrown out.

In soil that will allow it, tunneling will often save the public and individuals much inconvenience by carrying the trench under crosswalks, driveways, and railroad crossings, and the only tools needed are the tunneling-bars, mentioned in the list of tools, and long-handled shovels. A little practice and boldness in this detail will give very satisfactory results.

In these cases, bell-hole digging and joint-making must be done together, and some suggestions upon this detail will be given later.

With cast-iron pipe, when the digging is good and the trench stands up well, it pays to put three, four, or half a dozen men at work digging bell-holes; that is, enlarged places in the trench, spaced so as to come about the joints of the pipe, and large enough to give a man room to swing his hammer and get at all parts of the joint without unnecessary fatigue. There is little or no danger of getting the bell-holes too large, and plenty of room for the calker will do not a little toward insuring tight and strong work. The bottom of the trench should be dug out eight or ten inches for a length of four feet beyond the joint, and the sides worked out on the same scale to give ample shoulder room. These directions will have a queer sound when one is trying to make joints in quicksand, and at such a time fixed rules amount to but little. No end of grit, plenty of hard work, with some little planning will make joints in places that seem all but hopeless for the first half-hour.

Neither stony nor rocky trenches offer any serious difficulties, and even in ledge-work it is simply a question of time and money. If the bottom of the trench comes in rock which must be worked out by drilling and blasting, the ledge should be cut away to a depth which will allow sand six or eight inches in depth to be spread upon the rock, in which the pipe may be imbedded. If boulders are encountered which are too large to be taken out by the derrick, they should be well cleared from the confining

FIG. 14.

earth by digging before applying powder or dynamite; this gives the explosive a fair chance, and digging is cheaper than drilling and blasting. Large pieces may sometimes be worked off from a boulder or ledge which projects into the trench, without using explosives, by means of small hand-drills and "feathers and wedges." To do this, drill $\frac{3}{4}$ -inch holes with a short steel drill and stone-mason's hand-hammer along the desired line of fracture, eight or ten inches deep and six inches apart; drop a pair of feathers made of $\frac{3}{8}$ -inch $\frac{1}{2}$ -round iron into each hole and drive the wedges between each pair. The "feathers and wedges" are shown in Fig. 14.

In blasting, the nitro-glycerine preparation known to the trade as "forcite-powder" is comparatively safe and gives better results than common gunpowder, for it will shatter

rocks more thoroughly and with less tamping. To fire a $1\frac{1}{4}$ -inch hole three feet or more in depth, take a whole forcite-cartridge, cut off perhaps half an inch in length, and set a percussion-cap pinched on to the end of a piece of fuse into this short piece of the forcite by boring out a small hole with a knife. Lower this into the hole and cover it with the remainder of the cartridge broken into small pieces between the fingers, and fill up the hole with earth tamped down with a stick.

Such a charge as that will let daylight into any rock that a pipe-gang is likely to encounter, but the blast should be carefully loaded with logs, timbers, or railroad-ties chained together, and covered with brush to arrest small pieces which may do damage if allowed to fly. This forcite-powder may be used to loosen a troublesome boulder, by simply poking a hole into the bank along side of it and tucking in a little of the explosive folded in an envelope and held in place by a slight packing of earth, or a cracked and seamy rock may be thoroughly split by dropping an envelope full of the powder into one of the cracks, and firing by cap and fuse in the usual manner.

Rocks which appear in the bottom of a wet trench are unwelcome enough, but it will not do to leave them in such shape that a pipe will be supported by them in the middle with the weight of the back-filled earth bearing on the ends lying in soft ground. If the expense of getting out the rock seems too great, the depth of the trench should be reduced until a firm and even bearing can be secured.

On all trenches that do not stand up well or that must be made wide to get out rocks, the long three-legged derrick, illustrated on page 462, will be found exceedingly convenient, for its range is wide, and it can straddle fences in a right handy fashion.

PIPE-LAYING.

Cast-Iron Pipe.—When a hundred feet of trench has been bottomed out it is time to make up the derrick gang, and begin the work of putting the pipe into the ground. For six, eight, and ten inch pipe six men are enough, and they should be strong, active, and intelligent laborers. Men who are employed in this gang generally expect perhaps twenty-five cents per day more than the average digger, and good men in the place are worth it. It is not well to let the fellows who may be first chosen for this gang think that they are indispensable, and if one of them happens to be off a day, do not hesitate to take any good man out of the trench to fill the vacant place.

The first thing that a green lot of men must learn is to raise and carry the derrick, assuming that it be of the three-legged style referred to in a previous chapter. It is to be raised, first, just as a ladder should be, by footing the bottom and walking it into an upright position; then let one man grasp the pin of the middle leg with one hand and the leg with the other, a man at each of the other legs holding them firmly, and carry it straight away five or six feet; spread the other two legs the same distance, and the derrick stands alone, though perhaps not very firmly. A little study of the structure will now show that the legs may be spread as far apart as need be, provided always that lines joining the feet of the derrick form either an isosceles or an equilateral triangle, the line joining the two outside legs being the base. In placing over the trench, the middle leg should stand on the side which has the largest quantity of earth piled upon it. The man who is to carry the third leg, as the derrick is moved along from pipe to pipe, should grasp the pin firmly when the time for moving comes, throw his weight towards the trench, and be careful to keep midway between his comrades who are carrying the outside legs, and they in turn should walk as close to the edge of the trench as practicable, resist the push of the derrick firmly, and keep about ten feet apart.

A man at each leg, another to carry the rope, and two men in the trench, make an ordinary derrick-gang; for handling 16-inch pipe more men will be needed in hoisting and placing. The smaller sizes of pipe can be brought from the side of the road to the trench by means of the carrying-sticks. These sticks thrust into a pipe give good lifting hold, and two stout fellows at each end, shoulder to shoulder, will carry 4-inch easily, and 8-inch without overwork. Skids of 4x4 spruce thrown across the trench may support the pipe while the derrick is put in place over it; a sling of rope is then to be passed around the pipe enough nearer to the bell than to the spigot end, to cause the spigot end to fall easily into the trench when the pipe is lifted by the tackle from the skids. As the skids are removed to allow the pipe to be lowered into the trench, let one of

the gang bunt the pipe with the end of the skid to clear the pipe from sticks, stones, and dirt. This is not enough, however, and it should be the duty of the men in the trench to look through the pipe as it comes down to them and make sure that no one has either maliciously or carelessly left therein an old hat, or a pair of boots or overalls. These remarks are not in jest, for just such combinations of what the doctors might call incompatibles have been made.

As the pipe is lowered, one of the trenchmen enters the spigot into the preceding bell, his comrade assisting as best he can, but before the pipe rests on the ground it is well to swing it like a ram against the pipe already laid to make sure that the joints ready for calking are all "home." As soon as the pipe rests on the bottom, the foreman should straddle the trench at a convenient point ahead of the derrick, align the pipe just laid, and look back over the line for joints which may be improved.

The trenchmen should carry bars with them to throw the pipe, and not try to use shovels for levers. Attention should be given to vertical alignment, as well as horizontal, and if grades are not given by an engineer, and no use is made of a carpenter's level on the pipes, the vertical alignment may be kept within bounds by keeping the joints of the same width at the bottom as at the top. If the bell end of a pipe when it rests on bottom is found to be too low, raise it with the derrick, throw rather more than enough loose dirt under it, and then drop the pipe down hard on this two or three times. As soon as the pipe is in position a few shovelfuls of earth should be thrown on to the centre of it to hold it, and if the trench is bad, the section between the joints may be half-filled at once, as this will support the bank and counteract any tendency to caving. With 4 and 6 inch pipe and a troublesome trench, two or three lengths may be put together on the bank, the joints made on dry land, and then with two derricks and careful slinging three lengths may be put into the trench at once without straining the joints. The few joints that must be made in the trench may, in quicksand, seem at first like hopeless cases, but persistence and no thought of ultimate failure have conquered the most cases that have come in the experience of the writer. In such instances it is useless to attempt to get the sand down so as to make the joint right through without stopping to dig out again. Let the calker stand on the pipe while a good man with a shovel, perhaps a lot of sod, and some pieces of plank clears away and holds back the stuff so that the joint may be yarned if not poured. If the sand rises as soon as the shoveling ceases, let the calker do all he can by quick work, and then rest while another attempt with planks, sod, pails, and shovels is made to make room for him. In general, whatever means are employed to make and maintain room for joint-making in quicksand, let the preparations be thorough; let the plank be driven as deep as possible and well-braced, sods provided in large quantities; have pails or a good ditch-pump, and good strong men who are not afraid to "pitch in."

In order to locate gates or special castings in a particular spot or to bring a joint into a more accessible location it is frequently necessary to cut pipe.

For this use an 8 or 10 pound sledge and the long-handled cutting-off tool illustrated in Chapter I.; put a skid under each end of the pipe, placing one directly under the line of cutting and get a firm and even bearing on the ground for its whole length. A line for the cutter to follow may be had by winding the end of a tape-line about the pipe and marking along the edge with chalk, but a little practice will enable one to guide the cutter as the pipe is slowly rolled on the skids, so as to make a square cut. The blows of the sledge should be rather light for the first time around, and then when the cut is well marked so that it may be easily followed, the blows may be swung in with vigor.

The pipe should at some stage of the work be carefully inspected for cracks, which are oftenest found at the spigot end. If a crack in a spigot end is very slight and so short as to be more than covered by the bell, we may not think it worth while to cut the pipe, but a long crack obliges us to waste nearly twice its length of pipe, for the cut must be made at least six or eight inches above the visible end of the crack, and even then the jar of cutting may cause the crack to run still farther into the sound metal.

(TO BE CONTINUED.)

AMERICAN SOCIETY OF CIVIL ENGINEERS.

A MEETING was held at the Society Rooms Wednesday evening, October 19, Past Vice-President W. H. Paine in the chair.

The first paper, presented through Mr. E. P. North, was on "Brick-Making in Sinaloa, Mex.," by Juan Josa Avela, Professor of Engineering in the Colegio Rosales, Cuiliacan.

The writer states that the material chosen is alluvium from banks of rivers that do not contain too much sand, and experiments are repeated to determine proper proportion of dung (horse or mule) to mix with it, to prevent bricks from breaking when placed in the sun to dry.

A drying-floor is prepared by leveling the ground and sprinkling with sand, then a shallow pit is excavated three or four yards square, in which the clay, dung, and water is mixed until plastic, then left until next day before prepared into bricks. The working force is divided as follows: four men carry tempered clay to drying-floor; two men to mold into brick; one man for turning them to permit even drying; two men carry bricks to kilns, and two men to stack in kilns, which contain 20,000 to 30,000 bricks. The arches of the stack for burning are adobe or sun-dried bricks 24x16x3 $\frac{1}{2}$ inches.

The following are names of bricks burned: Adovu, or common size, for house-walls, 18x9x3 inches; Ladrillo, for inside of ovens, thin walls, etc., 9x4 $\frac{1}{2}$ x2 $\frac{1}{2}$ inches; Tejas arqueados, for roofing-tile, 14x9x3 $\frac{1}{2}$ inches; Lozeta, or paving-tile, 10x10x2 $\frac{1}{2}$ inches. The standard price of the Adovu is, in the district of Sinaloa, \$8 per M.; at Fuerte, \$14 per M.; in Cucincau, \$10 per M.; in Mazatlan, \$18, and at the mines the price is often \$30 per M.

The roof-tile receives more care in fabrication and burning, which is done in square kilns, with walls eight to nine feet high, the floor being constructed of arches to hold the combustibles; but not more than five courses of tiles are burned at one time, and are handled with great care before burning. The fire is increased gradually until the smoke that settled on the walls of the kiln at first has burned off, and the tiles are vitrified, which is known by their becoming bright red. One thousand of these tiles cost from eight to twelve dollars, and are laid so as to cover a surface of 194 square feet, at a cost of five cents per square foot.

Mr. Flagg stated that the walls of Lima, Peru, were made of adobe blocks in the sixteenth century, and when taken down by Mr. Meiggs, after remaining in the wall three hundred years, were sold for a higher price than new blocks cost.

The next paper read by the Secretary was a description of the "Results of some Experiments of the Influence of Fineness of Sand upon Cement Mortars," by Emil Kuich-jing, C. E.

Owing to the constant differences with the contractors on the Public Works of Rochester, N. Y., as to the merits of cement and sand, they had tests made in the laboratory of Cornell University covering the following points:

First—Relation of the two brands of cement forwarded.

Second—Relation of the different sands forwarded.

Third—Amount of fine material admissible in these sands causing appreciable deterioration of mortar.

Fourth—Probable cause of deterioration of fine material that occurs in excess of amount so determined.

The two brands, Akron and Buffalo, were mixed with the standard pure quartz sand and also with fine-grained sand in the proportion of 1 cement 3 of sand, with the following result:

Cement, 1 part.	Same, 3 parts.	Tensile strength in lbs. per sq. in. after			
		3 Days.	1 Week.	2 Weeks.	1 Month.
Buffalo	Quartz.	16	75	31	51
Akron	"	11	11	16	32
Buffalo	Fine.	9	17	26	30
Akron	"	7	12	18	23
Buffalo	Neat.	133	127	145	173
Akron	"	113	119	125	149

Both brands stood the prescribed test for blowing.

It was found that 20 per cent. of material so fine as to force through sieve No. 5, having 170 meshes per lineal inch, could be admitted without sensibly injuring the strength of the mortar made in the proportions of 3 to 1.

Careful determination of the voids in the different sands and also of the voids in the cement were made, and upon carefully comparing the various results obtained it would seem as though the following conclusions were justified:

First—In making mortar with any of the above sands the cement in the proportion of 3 to 1 the voids in the given quantity of sand are not completely filled by the cement.

Second—Having given a sand consisting of a mixture of coarse and fine particles, these latter tend to decrease the voids in the sand by acting as a filling material, and therefore this sand will give a better result when used in making mortar 3 to 1, with the fine particles present, than it would if the fine particles were withdrawn by sifting.

Third—If, however, more than 20 per cent. of weight consists of fine material, this decrease in the voids is no longer noticeable, and the excess of water which must then be used to mix the mortar causes an additional temporary weakening of the latter. It was discussed by George S. Greene, C. Tompkins, C. E. Emery, and others.

The next paper read was by Mr. E. B. Noyes, a Resident Engineer on the Erie Canal, near Syracuse, which described some singular results obtained from tests made of different brands of cement. The writer states that the tests were not sufficiently extended to authorize any very absolute conclusions to be drawn, but are interesting. No. 1. The samples were made from different cargoes, but the six-months' test entirely from one lot. No. 2 were the results of 8 breakings, slow-setting and nearly 2 hours in taking $\frac{1}{4}$ wire and $3\frac{1}{2}$ hours for the $\frac{1}{2}$ wire. Fineness No. 50 Sieve, 84 per cent.; No. 100 Sieve, 73 per cent. In No. 3 there were also 8 samples prepared with fresh water and 6 samples with brine. Fineness No. 50 Sieve, 88 per cent.; No. 100 Sieve, 77 per cent.

For No. 4 there were eight tests with fresh water and six tests with salt.

For No. 5 there were eight samples.

For No. 6 a portion was made from cement fresh ground. A portion of same lot was put in paper bags and kept in testing room three months. The remaining part was spread in the air and stirred daily for fifteen days. The result of tests 3, 4, and 6 indicated that strong brine weakens cement more or less, but all brands tested are not affected alike.

BOSTON SOCIETY OF CIVIL ENGINEERS.

THE regular monthly meeting of the Boston Society of Civil Engineers was called to order at 7:30, October 18, by the President, L. Frederick Rice, at the society's room.

Professor L. M. Norton, of the Institute of Technology, read a paper prepared for the society by the late

Professor William Ripley Nichols, entitled, "The Action of Boston Water on Certain Sorts of Service-Pipes" (iron, lead, galvanized iron, and kalmlein).

Professor G. F. Swain gave a talk on matters regarding the dimensions of bridge structures. There were 44 members and 9 visitors present.

AMERICAN PUBLIC HEALTH ASSOCIATION.

THE American Public Health Association will convene at Memphis, Tenn., Tuesday, November 8, at 10 o'clock A. M., and continue four days. The meetings will be held in Young Men's Hebrew Hall.

The Executive Committee have selected the following topics for consideration at the meeting: (1) The Pollution of Water-Supplies; (2) The Disposal of Refuse Matter of Cities; (3) The Disposal of Refuse Matter of Villages, Summer Resorts, and Isolated Tenements; (4) Animal Diseases Dangerous to Man.

It is hoped that sanitarians, and others who have had experience and observation in these matters, will give their views to the association, and through it to the public.

The above selection does not preclude the presentation of papers upon other subjects; indeed, the Secretary has already been notified that papers upon other interesting topics will be presented. The association will therefore probably receive and discuss papers in all the chief departments of sanitary science.

The address of the President, Dr. George M. Sternberg, U. S. A., will doubtless be of great interest, following so closely the return from his South American and Mexican mission respecting yellow fever. It is expected the address will be largely upon recent work in bacteriology, in connection with private and public hygiene. Full reports are also expected from the various committees of the association. The Committee on Disinfectants will present a report, embodying the researches and experimental work of that committee during the year.

The headquarters of the officers and committees will be at the Gayoso. The first meeting of the Executive Committee will be held Monday, November 7, at 4:30 P. M. The subjects for each day's consideration will be stated the previous day, and an official programme will appear each morning. Ample time for discussion will be allowed under the rules of the association, and all discussions will be stenographically reported. The morning sessions will be adjourned at 2:30 P. M. daily, to permit the meeting of the Executive Committee, Advisory Council, and other committees.

Applications for certificates to enable members and those intending to become members, and their families, to obtain the reduced rates offered by the various railroad lines to Memphis, should be made without delay to the Committee of Arrangements, Dr. G. B. Thornton, Chairman, Memphis, Tenn. The Committee of Arrangements will immediately issue and mail to the members of the association a circular, giving information regarding reduced railroad fare, hotel rates, etc.; others will be sent a copy upon application to the chairman of that committee.

All papers offered the association become its exclusive property, will be copyrighted, and can only be published by consent of the Publication Committee. All reports and papers must be in the hands of the secretary by November 7, in order to receive the approval of the committee. After November 1 all communications to the secretary should be sent to Memphis, Tenn., care of Dr. G. B. Thornton.

The secretary would like, at the earliest moment, the names of all members of the association who have died since the last annual meeting, in order that proper mentions may be made.

Clergymen, teachers, engineers, architects, builders, and all interested in the practical work of the association, are cordially invited to be present.

Ladies are especially invited to attend the evening meetings of the association.

Irving A. Watson, M. D., Concord, N. H., is the Secretary of the association.

THE Michigan Engineering Society was recently incorporated at Lansing. Professors Green, Cooley and Davis, of the University of Michigan, at Ann Arbor, are among the promoters of the organization.

THE New Jersey Sanitary Association will meet at Trenton on October 28 and 29.

THE FALL OF THE PAROCHIAL SCHOOL BUILDING IN HARLEM.

THE cause of this melancholy disaster is happily no mystery and its lessons are too sharp and obvious to be unheeded, for a time at least.

Seven men, including the builder, Father Kirner, a Roman Catholic priest, lost their lives, and a dozen others were more or less seriously injured.

On the 6th of September last application was made to the Building Department to erect a two-story brick school-house at 443 East One Hundred and Fifteenth Street, at a cost of \$10,000, to be 100 feet deep, and thirty feet wide and high. On October 17 the application was amended to permit the addition of two more stories, increasing the height to fifty feet. Meantime, however, and without permission, the building had been run up to nearly that height, and while Mr. D'Oench, Superintendent of the Building Bureau, was examining the amended application the building fell.

The causes of the disaster are sufficiently set forth in his report. He says, first, that the mortar was of but "medium" quality; second, that the side and rear walls were carried nearly three stories higher than the front wall, while the law allows a difference of but two stories in height; third, that the wall was recessed improperly and without permission; fourth, that the walls were not strongly braced nor anchored to each tier of beams; fifth, that the piers, columns, and girders that were to have supported the centre of the floor-beams were not in place, some "flimsy scantling" being temporarily used instead, and not even that in the cellar; and sixth, that the walls were carried to a height of three and one-half stories when the permit allowed but two. He adds, that the walls left standing show dangerously rapid and careless workmanship and that the vibration caused by the hoist-elevator doubtless accelerated the catastrophe.

"Medium" is a very mild term to apply to this mortar. The bricks fell clean, and it was not easy two days later to find a lump of sufficient size and consistence to carry off as a sample. The inspector in charge of the district, Mr. William J. Martin, has since the accident officially reported that the mortar was of "first-rate" quality. He has probably done so on the strength of a statement, which in the same document he reports Father Kirner to have made, to the effect that he was going to erect a "good substantial building, as he was going to use it for a school."

Martin has since been dismissed on the following charges of neglect of duty: First, in failing to report unauthorized recesses in the walls; second, in failing to report that the building had been carried higher than the permit allowed; and, third, in failing to report that the side walls were more than two stories higher than the front walls. He pleaded guilty to the first only, although his own admissions convicted him of all three. The only palliation of his offence is given apparently without intention in the last part of the report of Mr. D'Oench, where he states that each inspector has on an average over 110 new buildings and alterations which he is expected to examine and report on each day.

Since the above was written we have learned that Martin has been arrested and held in \$5,000 bail.

ST. PETERSBURG EXHIBITION.

A PERMANENT technical exhibition and exchange has been opened in St. Petersburg, under the patronage of the Minister of the Interior and Public Works, and by the Association of Engineers of Ways of Communication, which seems to be worthy of being brought to the attention of the American people. It proposes to cover the entire field of civil, mechanical, and sanitary engineering, railroad equipment, and manufactures, each department to be in charge of specialists in that particular line. Its especial object purports to be the development of trade between Russia and foreign countries. The Russian Government has shown a tendency to construct its own great works, rather than to entrust them to private individuals or firms, and the Government is reported to be in need of quantities of various engineering supplies, such as will be exhibited in this display. The exhibition will also act as an agency to effect sales for exhibitors and others, and to facilitate the business of patent solicitors in securing Russian patents. Mr. A. Warschawsky, 14 Dey Street, New York City, has been appointed general agent for America. Particulars may be obtained of him.

DOMESTIC ENGINEERING, ETC., IN THE
EQUITABLE LIFE INSURANCE BUILD-
ING, NEW YORK CITY.

No. III.

(Continued from page 554.)

FEED-WATER PIPES.

THE arrangement of feed-water pipes is as follows: Beginning at the feed-pumps W W—which are H. R. Worthington duplex—the feed-water is discharged through pipe X, which is three inches diameter and runs along the front of the boiler-domes to the heater R, the heated water returning by pipe Y, which runs parallel with pipe X, discharges the hot water to the several boilers through the branches 46, 47, etc.

When the heater is not in use the valves 48 and 49 are closed and valve 50 opened, then the feed-water goes direct to the boilers without going around the loop made by pipe X.

The feed-pumps and pump-governors Z Z will be more fully explained hereafter.

HYDRAULIC-ELEVATOR WATER-SERVICE.

The elevator water-supply main is 16 inches diameter. Its position is fully shown in the cellar plan near pumps. (Fig. 1) and it is shown in cross-section in pump elevation, Fig. 2. Two of the three elevator pumps are constantly at work during business hours discharging their contents into it through 12-inch discharge-pipes. This main is tapped at five places, marked 51, 52, 53, 54, 55, by 10-inch pipes that go directly up the shafts adjoining the elevator-wells to the top of the building, where they are each connected to a pair of cylindrical tanks partially

FIG. 2.

filled with water. In addition to these ten hydraulic elevators, water is supplied from this main through the 3-inch galvanized pipe marked 56 to the private elevator of the President of the Mercantile Trust Company, which elevator operates from the first to the "Equitable" floor. Another pressure water-main (57), which is connected to the branch marked 51, conveys water to operate the "ram" elevators 58 and 59 located in the offices of the Mercantile Safe Deposit Company's vaults, and used for hoisting and lowering valuables and coin from one floor to the other.

Still another pressure water-main, not shown, operates the private elevator of the President of the Equitable Life Assurance Society, the elevating mechanism for which is located on the ninth floor.

FILTERED WATER FOR HOUSE USE.

The system for supplying the offices and building generally with pure filtered cold water is very complete. The Worthington pump E, cellar plan, is devoted to this purpose. The suction is connected to the storage-tanks 62 and 63, which are supplied from the city water-mains. These tanks have a united capacity of 10,000 gallons, and are kept filled in case the city mains should temporarily fail in their supply. Water is drawn from them through suction-pipe 90 to pump E; thence is forced to tanks at the top of the building; thence, by a 6-inch main, back again to the cellar. The 6-inch main is

carried around the cellar, and, by risers, is connected to the different pipe-lines throughout the building. This enables the engineers in charge, in case of trouble in any part of the building or system, to cut off any single line of pipe from the cellar, avoiding the delay of going to the top of the building to shut off the water at the tanks, as is often the case, and leaving but a limited number of tenants without water, instead of cutting off a large section of the building.

The suction of the Worthington pump, D, is also connected to the storage tanks 62 and 63, and the discharge to the overhead tanks by pipe 91, in case the pump E should be disabled, its regular duty being for elevator use on Sundays and holidays, for which purpose the suction is also connected to the water tanks P P, as shown in dotted lines 61, while a separate discharge is connected to branch 54 of the water-main at 92.

Each hydraulic elevator has an independent supply-pipe seven inches in diameter running from the overhead tanks down the supplementary shafts adjoining the elevator-wells to the elevators located in the cellar, and shown in cellar plan. Although representing in the aggregate about 1,300 feet of pipe, they are simply designated on the drawing by ten very small circles. The horizontal part of these pipes are numbered 64, 65, 66, 67, 68, 69, 70, 71, 72, 73.

The three pipes to each pair of passenger elevators—viz., the 10-inch riser and the two 7-inch supply-pipes—all rest on two strong pieces of I-beam extending across the pipe-shafts from wall to wall. Some distance from the bottom of each discharge-pipe, corresponding with the height of the ceiling, is set a tee, from which connection is made to the elevators, in the most direct manner the walls of the building will allow, in each case.

Each elevator is also supplied with an independent 6-inch discharge-pipe running clear from the elevator to the elevator water tanks P P. These discharge-pipes are marked respectively 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, the figures being placed conveniently near the elevators. It is arranged so that each discharge-pipe will discharge into both or either of the tanks P P, so that if one tank is undergoing repairs, or being cleaned, the other can be made to do all of the work.

THE BOILERS.

The steam for all purposes is furnished by nine boilers, rated nominally at 100 horse-power each (see Fig. 3). They are set side by side in pairs, with one exception, and

FIGURE 3.

are of the horizontal tubular pattern, 16 feet long by 5 feet 6 inches diameter, of $\frac{3}{8}$ -inch steel; each boiler is furnished with a dome 36 inches diameter and 36 inches high, and 58 4-inch tubes.

The heads are $\frac{1}{8}$ -inch flange steel; the longitudinal seams are double riveted; the calked edges of the sheets are planed beveling; all the rivet holes were drilled; no drifting was allowed; the tubes were ordered expanded by Dudgeon Expander.

Each boiler has a manhole 11 $\frac{1}{2}$ " x 14 $\frac{1}{2}$ ", and two handholes, one in front 11" x 8", and one in back 7 $\frac{1}{2}$ " x 4 $\frac{1}{2}$ "; both manholes and handholes are strengthened with heavy cast-iron rings, firmly riveted to the shell and heads.

Steam is delivered through 6-inch wrought-iron pipes tapped into cast-iron flanges riveted on the front of the domes near the top (see Fig. 3). These pipes connect with the 14-inch pipe already mentioned, which is suspended from the ceiling and runs the whole length of the building.

battery of boilers about 4 feet from the line of the boiler fronts. The feed-water pipes enter through the front head at a point below the lowest tube. The blow-off pipes, 2 $\frac{1}{2}$ inches diameter, are placed on the bottom of the shells just in front of the back heads; the exact arrangement is shown in Fig. 3. The pipe A leads to the sewer in the usual fashion, but the pipe B, leading to the top of the boiler and down into the steam-room, is an addition to the usual practice, which has been found by some nine years of trial to be a complete preventative against the filling up of the blow-off pipes with scaly matter.

The action of the device is as follows: Pipe C, being in a very hot and effective part of the furnace, keeps the water therein in a high state of ebullition as compared with the water in the adjoining part of the boiler; as a result the water is violently projected upward through pipe B, and deposited into the steam-room, thus making room for a constant inflow to pipe C from the water in the back end of the boiler. The device is the unpatented invention of Mr. Wilson, the superintending engineer. Its action seems to be all that is claimed for it.

Each boiler is furnished with a fusible plug at the water-line that will melt out when the water gets too low in the boiler. Eight heavy lugs are riveted to each boiler; they rest on 1 $\frac{1}{2}$ -inch rollers placed in box-castings, shown at D, that are built in the wall. A large door is placed in the back connection for easy inspection and cleaning.

The fronts stand out 15 inches from the boiler proper and are fitted for the Ashcroft grates and doors; the large front connection doors are lined with fire-resisting material put on in sheets 1 $\frac{1}{2}$ inches thick bolted into place. The pressure of steam carried is 80 pounds above the atmosphere; the boilers were tested by water-test to 150 pounds per square inch before delivery; they were put in place and connected up by the chief engineer's own men.

The connection to the chimney is made by one branch spanning two boilers and uniting in one rectangular flue 30x36 inches, and running along the top of the brick-work of the boilers to the back where they join the main flue, thence to stack (see cellar plan).

The main feed-water pipe for all the boilers runs along the front of the domes just below the 6-inch branch steam-pipes that connect to the 14-inch main. This pipe is 3 inches diameter and made of annealed brass tubing. The feed branches that lead over to and down the front of the boilers are also made of brass tubing, the object being to avoid the frequent repairs incidental to iron pipe when

used for that purpose. The usual combination gauge and water-glass stand is also of brass. A globe-valve is placed on each of the 6-inch steam-branches near the dome, and the pipes turn upward as high as the ceiling will allow, and down again to make connection on the top side of the 14-inch main. This arrangement forms an inverted U, and is done to allow properly for expansion.

All of the steam-pipes, flues, and other hot places are covered as completely as possible with non-conducting material furnished by the Magnesia Sectional Covering Co., of Philadelphia, Pa. This material is put on in sheets, which are held in place by iron-bound fastenings, so that it can be removed for repairs or changes.

ENGLISH PLUMBING PRACTICE.

BY A JOURNEYMAN PLUMBER.

No. LXX.

(Continued from page 491.)

HOT-WATER CIRCULATION (CONTINUED).

TO CARRY out hot-water work in a thoroughly efficient manner, a man requires to know all the principles which govern his work. If he does not know these principles he is always liable to blunder in the arrangement of the fittings and pipes. A man may be a good tradesman and fix new work that will answer first-class and yet very often be at a loss to know how to alter other work that has been improperly done by some one else.

Figure 1 is an illustration of a job near Regents Park in London. A is a $\frac{1}{2}$ -inch expansion-pipe, B a $\frac{3}{4}$ -inch flow-pipe, C a $\frac{1}{2}$ -inch return-pipe, D a 30-gallon cylinder, E a $\frac{3}{4}$ -inch draw-off pipe, F a $\frac{1}{2}$ -inch cold-water feed-pipe, and G a small feed-cistern with a $\frac{3}{8}$ -inch ball-valve. The top of the feed-cistern was fixed nearly level with the top of cylinder. The talented expert who arranged this work was ignominiously dismissed, and another man was called in who spent several days in altering the work, but still could not see how it was that no water could be drawn at the cock H. Eventually, he fixed another expansion or vent pipe as shown by dotted lines at I, when he succeeded

in getting a small dribble of water at the bibb-cock. A large fire had been kept up, with the result that sometimes the water was forced out of the feed-cistern and steam drawn at the bibb-cock when opened. This was before the second expansion-pipe was fixed.

The second man having been sent away, the owner thought perhaps it would be an advantage to go to a respectable firm of engineers instead of employing cheap men who knew nothing about the principles which govern the work. He was very much surprised when he was told that the whole of the pipes would have to be changed to a larger size and differently arranged.

Figure 2 shows the alterations, which may be enumerated as follows: The pipe leading to the draw-off cock was branched into the flow-pipe from the boiler to the cylinder. The pipes between boiler and cylinder were made one inch in diameter. The expansion or vent pipe was fixed from the top of the cylinder and the feed-cistern was fixed at a higher level. A larger service-pipe and ball-valve were fixed, and also a larger pipe from the feed-cistern to the bottom of the cylinder. A damper was also fixed in the boiler-flue so as to regulate the draught. On being told that there was plenty of hot water and enough to supply a bath, the gentleman was so pleased that he had fixed in an adjoining room.

Figure 3 is an illustration of another blunder which was, if possible, worse than the last one described. This was fitted up in a nobleman's mansion in London by a village blacksmith, in whom his lordship had so much confidence that he paid railway and other expenses sooner than trust to any one in London. The strange part about this arrangement is, that the water in the cistern K did sometimes get hot, but was never to be depended upon for heating. At times it was found necessary to open the cock L, as air would accumulate in the horizontal pipe M. The only alteration made in this case was to fix a vent-pipe as shown by dotted lines at N, and connect the return-pipe from the hot-water cistern to the boiler as shown by dotted lines at O.

Figure 4 was a rather strange experience of erratic circulation. A boiler was fixed for heating water to supply sinks in which bottles were washed at a wholesale wine merchant's. Two radiators were fixed as shown in the diagram for heating the offices. The coil P got very hot, but there was no heat in the coil Q so long as there was a fire under the boiler. But on allowing the fire to go out the water would at once begin to circulate backwards and the coil Q got moderately warm, but on again lighting the boiler-fire this coil would gradually get cool again. As the whole of the work appeared to be done in good and workmanlike manner, some little thought was necessary before it could be understood why one coil got hot and the other did not, when the boiler-fire was alight, and yet on putting out the fire the circulation was reversed. The pet-cocks on the coil-heads were opened, but as water came in each case there was proof that they were not air-bound.

Two mistakes suggested themselves. One was the pipe from the boiler was too small, being only $\frac{1}{4}$ -inch, and the branch to the coil Q was at right angles, but horizontal. The return-pipe was branched into the main return-pipe as shown in the sketch. This branch being upright accounts for the back action in the circulation. The alterations made were as follows: 2-inch pipes were fixed from the boiler as far as the branches to the coil Q, and the flow-pipe branch was turned upwards as shown by dotted lines. The alterations, when made, proved to be successful, as both the coils heated equally.

In another case a long branch pipe was fixed to supply a pantry sink. This pipe was returned so that water would circulate through it, and thus avoid having to empty the pipe of cold water before hot could be drawn. It was found that no circulation took place. The way it was branched is shown at Fig. 5, S being the main flow and T the main return-pipe, and U the way the draw-off pipe was branched, so that any pent-up air could escape when the bibb-cock was opened. Figure 6 shows the alteration made, the branch flow being taken off the top of the main flow as shown at V. The issue was successful and hot water freely circulated through the branch pipe, which was about forty feet in length.

The last two problems in hot-water circulation are typical of a great many mistakes made by men who may be compared to pieces of machinery, who can execute work in a fairly good way, but who lack the necessary experience or knowledge to properly plan or arrange the scheme before commencing to carry it into execution. Other examples could be given, but those cited are sufficient to set the reader thinking, and, if he is a practical, man may perhaps prevent him making similar mistakes.

In some instances fire insurance societies insist that no hot-water pipes shall be in actual contact with, or within several inches of, any wood-work. Where of necessity the pipes must be fixed close, the wood-work has to be covered with sheet-metal or be otherwise protected.

When pipes are carried beneath wood flooring, and rooms, etc., are beneath, it is always advisable to construct a proper channel for the pipes to lay in, and line the channel with sheet-lead. This metal lining not only keeps the pipes away from the wood-work, but should the pipes leak, the water is caught, and, running to the lowest end, the bottom of the channel being laid to the same declination as the pipes, can be conveyed

away by means of a waste-pipe fixed from the channel to a suitable position for discharging. It is also a good plan to lay the hot-water pipes on small rollers, which can be made of remnants of iron pipe, so as to keep the circulation-pipes further away from the wood-work, and also allow them to move freely when expanded or contracted by differences in temperature. These rollers should not be too far apart, or the pipes will sag down between them, thus allowing air or vapor to lodge in the high parts and cause a partial obstruction.

It is important that the cold-water supply-cistern should be fixed a fair height above the highest draw-off cock, and, as stated in another chapter, that the cold-water supply-pipe should be a good size—that is, larger than any of the branch or draw-off pipes. This has again been brought to the writer's notice at a house where complaints were made that very often no hot water could be drawn on the upper or chamber floor for a minute or two at a time, when it would begin to run at the tap and perhaps immediately afterwards stop again. On seeking for the cause of this, it was found that sometimes one or two taps were opened on the ground floor for drawing hot water at the scullery or pantry sinks, during which time none could be drawn on the floor above.

Figure 7 is a sketch diagram showing the position of the cold-water cistern, cylinder, boiler, tinned copper circulation and draw-off pipes, etc. To remedy the evil, all the cocks on the ground floor were pea'd—that is, a copper disk, with a small perforation, was inserted in the bosses, so that the water did not run quite so fast when the cocks were opened. A $\frac{1}{4}$ -inch pipe was fixed from the cold-water cistern to the boiler. The cold-water cistern was only four feet above the level of the highest draw-off cock, and this cock was one of great importance, as it supplied the principal bath-room, which was used by a nobleman. The above alterations were found to improve matters very much, but at times no hot water could be had at the above-named cock, so it was deemed advisable to fix a 20-gallon tinned copper cylinder, as shown by dotted lines at W, the circulation-pipes being so connected that the cylinder could only be emptied by opening the cock attached to it. This arrangement was to avoid the contents of the cylinder running back into the circulation-pipes when they were being drained by cocks at a lower level, and was found to be fairly successful, although some time had to elapse before the lower strata of cold water was heated to the same extent as the upper portion of the contents of the cylinder.

In the diagram X was a coil made of $\frac{1}{4}$ -inch copper pipes, nickel-plated, and was used for warming the bath-room, and also the bath-towels.

(TO BE CONTINUED.)

AN ELECTRIC WATER-TANK INDICATOR.

WE illustrate here an apparatus for indicating the depth of water in a tank, designed by a lad 16 years of age, now attending the high school in Boston—William A. Tucker, a son of Colonel Tucker, of the firm of Tucker & Titus, of that city. By reference to the sketch it will be noticed that when the tank is empty the end of the float-lever touches at "A," ringing a gong-bell "B," and at the same time causing on the annunciator the word "empty" to appear. The engineer can then turn the switch-valve "C" to stop the ringing of the bell, and start his pump. When the tank is full and the lever is released from "A" and touches "D," the bell rings again and the word "full" is shown on the annunciator. The switch is then turned again and the ringing of the bell stopped. It gives us special pleasure to illustrate the work of young men, and we hope our readers will bear this in mind and call our attention to their efforts in any department that comes within the scope of this paper.

HOW NEW YORK PLUMBERS MAY PROTECT THEMSELVES.

THE President of the Health Department of New York has sent the following letter to Mr. Alexander Lowe, Secretary of the Master Plumbers' Association, which is of interest to all connected with the plumbing trade. The plumbers have been very careless in the matter of ascertaining whether they are protected by the approval, in writing, of the plans and specifications furnished them, and have risked a great deal in beginning work subject to the approval of the board when it might suit the owner or architect to file plans. After the notice thus given them they will have no reason to appeal to the good nature of the Board of Health to help them out of the difficulties they invite by neglecting the simple precaution of ascertaining whether the plans and specifications are legally approved:

Mr. Alexander Lowe, Secretary Master Plumbers' Association:

DEAR SIR: Please call the attention of members of the Master Plumbers' Association, and, as far as possible, of the trade at large, to the importance of ascertaining whether the plans and specifications to which they are called upon to work are approved by the Board of Health in the shape in which they are furnished by architects and owners. This can be done by inquiry at this Department. When it is neglected, the plumber may unconsciously fall into a snare from which he may find it difficult to extricate himself. For example, a plumber about to begin work on a contract to pipe four buildings called at Department Headquarters a few days ago to make sure that the specifications furnished him were duly approved. Upon examination it was found that the specifications had been originally approved for a house which was never built, and had been altered by some unauthorized person and made to cover four houses in another location. These specifications were approved under the old rules, and had work been begun it would have been stopped as soon as the violations were discovered and reported by one of our inspectors. This would have entailed inconvenience and loss to the plumber, and it would have been impossible for the Board of Health to have done anything for his relief during the proceedings against the owner. Instances have also come to our notice in which the specifications furnished the plumber to bid on and work from have been very different from those approved by the board. The plumber under such circumstances might be guilty of wrong intent, but he would be none the less seriously compromised by his position, and could not avoid inconvenience and loss. The Board of Health cannot overlook violations of the law, even where the plumber honestly believes himself to be working from approved plans and specifications. We offer him every facility to advise himself in advance as to what the board has approved, and the protection thus secured is worth all the trouble involved in the inquiry.

Attention is also called to the fact that, under the new rules, the approval of the Board of Health is withdrawn if work is not begun within six months of the date of such approval, and that plans must again be presented for approval if subsequently made use of.

By promulgating this information the best interests of the trade will be served. Under the law it is a misdemeanor for a plumber to proceed with new work, "unless the plans have been previously approved in writing by the Board of Health." It is our duty to enforce this law, and we shall be compelled to proceed against plumbers who violate it.

Respectfully,
JAMES C. BAYLES, President.

Correspondence.

All correspondents should send us their names and addresses, not necessarily for publication, but as a guarantee of good faith and because it is often necessary to communicate with them for additional information before printing their communications. Anonymous letters will not be noticed.

ON THE DISCHARGE OF STEAM INTO SEWERS OR SOIL-PIPES.

OFFICE OF THE SEWER COMMISSION,
AMSTERDAM, N. Y., October 13, 1887.

SIR: Several specifications for plumbing contain the following: "No steam-exhaust, blow-off, or drip-pipe shall connect with the sewer or any house-drain, soil-pipe, or waste-pipe." To settle a difference of opinion, will you please give me your ideas as to connecting blow-offs and drip-pipes with a modern system of small-pipe sewers? Yours respectfully,
WILLIAM B. LANDRETH.

[The connection of steam and sewer-pipes is very objectionable for two important reasons—first, on account of the damage which may be done to a brick or cement-pipe sewer, and especially to the joints of the latter by the steam or hot water, which also injures lead joints in iron pipe, the iron expanded by heat compressing the lead and causing the joint to leak when cool; and second, that if the steam is discharged in sufficient quantity it escapes through every opening, carrying with it the deleterious emanations of the sewer.

If for any reason it is not convenient to dispose of the steam and hot water otherwise, they might be conducted to a well-ventilated cesspool through a sufficient length of exposed pipe to insure complete condensation and reasonable cooling. The discharge from such a cesspool could be safely received by the sewer.]

HEATING A GREEN-HOUSE.

SEPTEMBER 29, 1887.

SIR: We submit a ground plan and section of greenhouse, with dimensions, and which we would be pleased to have your ideas upon, and instructions with regard to how to make a neat job, and one that will heat properly the space—say, when the weather is down to 20° below zero. It is in the city, and we want to make a neat job of it. We want you to render us advice as to location of stand-pipes or tanks, air-cocks if you advise any, or other stops if used; the best means to obtain a good circulation and proper heat with the least amount of 4-inch pipe; the best compound for rust joint, etc. The boiler is shown at B, with the two top outlets as shown. Now, will you draw in colored or lead pencil lines the runs and the number for the side and middle beds and returns (the return-outlets are on bottom of boiler, not shown), and mark sections of the pipes on the section plan? Boiler is located in the pit where stairs go down.

Mark location of stand-pipes or tanks, and return sketch as quickly as possible, for the work must be done as quickly as possible. The season is getting late; and give us the proper grade you would run the pipe.

Any pipes run near or on path at the office will be boxed with steps, but we do not want to cross the rear door with the pipes if it can be avoided. You can give sufficient instructions to work good results without any further statement from us.

Size of boiler used, 30x48 inches. Approximate heating power of 4-inch pipe, 1,250 feet. Heating surface, 4,082 square inches.

FITTER.

[The glass surface of your building is about 2,400 square feet. A good common rule to follow in so cold a climate, in determining heating surfaces for greenhouses or nurseries, is to allow one foot of 4-inch pipe to each two square feet of glass in a perpendicular form. This would call for 1,200 feet of 4-inch pipe.

In your case, however, the usual slanting roofs prevail, and in this case one foot of pipe to three of glass is considered enough. This would call for 800 feet of 4-inch pipe. It will be noticed in your plan that the total length of your outside "benches" or beds is about 200 feet. If you use four pipes the length of these beds, it takes about the length of pipe you require. You can, in your judgment, use all this pipe under the outer branches, or you can divide it and use some under the inner ones, though the latter we do not advise, as we consider it unnecessary.

From your plan we assume the boiler to be on the level of the floor. In such a case you will have to use your expansion-tank near the boiler, so you can place the doorways. Place the tank high up, and coils, which presumably you will for beds, take four separate flow-pipes to the

all doorways, etc. This may compel you to take the flow-pipes for the right-hand side out of doors. In such case use two flow-pipes from the boiler to two expansion-tanks, placing one in each house high up; then flow from the tanks to the coils. In returning you can carry the return-pipes with a little dip to get past the doorways. Let the pipes have a slight downward inclination and you will require no air-cocks.

We know nothing of the boiler you ask us about.]

HEATING A DOMESTIC BOILER BY STEAM.

CORTLAND, N. Y., October 6, 1887.

SIR: Is there such a thing done as heating a thirty-five gallon galvanized-iron boiler by live steam, and would you be so kind as to inform me, and explain what you think about the matter?

CONSTANT READER.

[Mr. John Tucker, of the firm of Byrne & Tucker, New York, has devised several methods of applying steam to the warming of the water in an ordinary boiler, the sim-

plest of which is to run a steam-pipe through the boiler from top to bottom, using a stuffing-box on one end, so as to allow for the difference of expansion between the iron of the boiler and the pipe.

This is shown in principle in the illustration which we give. We are not aware of any merchantable apparatus for this purpose, but are of the opinion that the gentleman who first used it to our knowledge will not object to the use of it by any one who is desirous of making it.]

E. G. LOVE, Ph.D., Gas Examiner.

THE fifteenth annual meeting of the American Gas-Light Association was held in Dockstader's Hall, in this city, on Wednesday, Thursday, and Friday of this week. One hundred and fifty members were present, and twenty-eight new members elected. Papers were read on "Water-Gas," by Walton Clark; on "Illumination vs. Candle-Power," by Alexander C. Humphreys; on "The Relation of Intensity of Light and Visual Perception," by Edward C. Jones; on the "Utilization of Residual Products," by Charles H. Nettleton, and on "Fuel-Gas," by Emerson McMillen. Professor Henry Morton, President of the Stevens Institute, and an honorary member of the association, was present and took part in the discussions. The next annual meeting will be held in Toronto. The following officers were elected for the ensuing year:

President, Thomas Turner, Charleston, S. C. Vice-Presidents, A. B. Slater, Providence, R. I.; Emerson McMillen, Columbus, O.; J. P. Harbison, Hartford, Conn. Secretary and Treasurer, C. J. R. Humphreys, Lawrence, Mass. Finance Committee, C. H. Nettleton, Birmingham, Conn.; A. E. Boardman, Macon, Geo.; William H. Pearson, Toronto, Ont. Executive Committee, William Henry White, New York; G. G. Ramsdell, Vincennes, Ind.; H. B. Leach, Taunton, Mass.; D. G. Geggie, Quebec, Canada; T. G. Landsden, Washington, D. C.; F. S. Benson, Brooklyn, N. Y.

On Thursday evening a banquet was held at Lyric Hall, and on Friday an excursion was made around New York Bay and up the Hudson River.

FALL OF A RETORT-HOUSE ROOF.

LAST Sunday the roof of the retort-house of the Metropolitan Branch of the Consolidated Gas Company on Forty-second Street, between Tenth and Eleventh Avenues, in this city, fell in, injuring four men more or less seriously, though none, it is thought, fatally.

The building, a one-story structure of brick, 26x60 feet, and about 20 feet to the eaves, was erected in 1862.

The arrangement of the roof is shown in the accompanying illustration, which gives a little more than one-half of a truss.

The trusses were spaced 5 feet apart and were composed of $4 \times \frac{1}{2}$ -inch rafters and $1 \frac{1}{4}$ -inch tie-rods, the secondary struts and ties being all of round iron from $\frac{3}{8}$ to $1 \frac{1}{2}$ -inch diameter. The purlins were $1 \times \frac{3}{4}$ -inch and 9 inches apart. Purlins and rafters were each notched $\frac{1}{4}$ -inch at intersections, so as to bring their upper edges flush, and the covering of slate was wired directly to the purlins, which alone prevented the lateral deflection of the rafters.

For a distance of 4 feet 6 inches at A, and about an equal distance at B, there were no purlins and consequently no lateral support for the rafters.

The roof began to collapse at or near the east end, and the ruin spread at a very moderate speed for the whole length of the building, bringing down every truss, but giving most of the workmen time to escape. Nearly or quite all the rafters buckled at A on the south side, pulling the trusses in from the south wall and bringing the cast-iron gutters with them, but not otherwise materially injuring the walls, which were 16 inches thick, with 4-inch buttresses.

The retort-walls, which reached nearly to the tie-rods, prevented the trusses from falling very far.

Just what gave way first it is difficult to determine. A tie-rod, broken in a poor weld near where the collapse began, seemed at first the probable cause, but further investigation showed it more likely to have been the consequence of the disaster.

The fact that all the trusses that fell last buckled at A showed that to be the weakest point, and that each should have followed its neighbor so promptly shows that the margin of safety was exceeding small.

At A the rafter was in the condition of a column whose unsupported length exceeded 100 times its thickness, and its compressive strength was thereby reduced to one-fifth of what it would have been with proper lateral support. That it gave way is not so remarkable as that it should have waited twenty-five years before doing it.

Several fractures showed the iron to be stiff and brittle, though perhaps of fair tensile strength. Its stiffness saved it from an earlier fate. Had its ductility been up to modern requirements, it would probably have succumbed to the first snow-storm.

There was not much corrosion, and that very irregular. Several tie-rods had been reinforced on that account near the wall, but one, though reduced to nearly one-fourth of its original area, still held without assistance, giving additional support to the theory that the accident was due to the buckling of the rafters.

If the *Gas Engineer* is correctly informed, the Central Telegraph Department of the English Post-Office is to be fitted up with 50 Welsbach incandescent gas-lights.

REPORT OF THE HEALTH OF LIVERPOOL.

THE report, by Dr. J. Stopford Taylor, the Medical Officer of Health of Liverpool, for the year 1886, consists for the most part of tables of vital statistics. From these it appears that the improvement which has been going on for the last five years in the health of the city still continues.

The death-rate for the year was 23.7 per 1,000, the same as that for last year, and 2.9 per 1,000 less than the average rate for the last ten years.

The density of population in Liverpool is greater than in any other city or town in Great Britain, being in the proportion of 112.5 per acre, or a little over double the density of London—i. e., 55 per acre. It also has a large floating population, many of whom are dissipated and improvident, and its mortality must be always comparatively high.

Dr. Taylor thinks that if there is to be any further reduction in mortality from zymotic disease it is necessary that proper hospital accommodation be provided for the isolation of the earliest cases. It seems that heretofore this has been provided by the workhouse, but that this is no longer available.

The work of purchasing and destroying insanitary property continues, the number of houses demolished for this cause during the year being reported at 337. Fifty-seven tons of unwholesome meats and 50 tons of unwholesome fish were seized and destroyed.

The number of articles disinfected at the public disinfecting apparatus was, 28,270; including 2,175 beds; 2,987 mattresses, and 13,569 pieces of bedding. This will give an idea of the use that is made of this apparatus.

The report is accompanied by a map of Liverpool on which are noted the location of deaths from fever during the year, and, taken as a whole, gives a good idea of the great variety and magnitude of the sanitary work required in a sea-side port of nearly 600,000 inhabitants.

FROM the twentieth annual report of the Health Department of Cincinnati, for the year 1886, prepared by Dr. Byron Stanton, who was appointed Health Officer in September, 1886, we learn that the number of deaths during the year was 6,170, which, on an estimated population of 325,000, gives a death-rate of 18.98 per 1,000. The most prevalent epidemic disease was measles, of which 1,593 cases were reported, causing 145 deaths. Diphtheria is reported as having caused 195 deaths, besides 169 deaths reported as due to croup, many of which were, no doubt, diphtheritic. Typhoid fever caused 151 deaths, and 850 deaths are reported as due to consumption. The mortality from cancer is high, 124 deaths, giving 38.1 per 100,000 of population.

Dr. Stanton points out that the sewerage is insufficient and advises extension of the system and the making compulsory that house-connections be made with them, and reiterates the warning given in the reports of his predecessors as to the danger which exists from contamination of the water-supply of the city by the discharge of sewage into the river above the intake of the water-works.

The report of the Milk Inspector, Dr. T. Bange, shows that 2,127 samples of milk were tested, of which 54 were found below the standard. The standard adopted is that "Milk must not contain more than 87 per cent. of

water and not less than 13 per cent. of total milk solids and not less than 9.3 per cent. of solids, exclusive of fat."

The expenses of the department for the year were \$41,959.84.

FREDERIC W. VAUGHAN.

FREDERIC W. VAUGHAN, President of the Louisville Bridge and Iron Company, died suddenly at Louisville, Ky., on Wednesday, 19th inst. Mr. Vaughan was born at Warren, Knox County, Maine, on June 6, 1844, graduated at the Rensselaer Polytechnic Institute in the Class of 1863, and was elected a member of the American Society of Civil Engineers in 1869, of which he once served as a director. He went to Nashville during the war as assistant engineer on Government railways and has since been prominently identified with most of the bridge construction of the central South. He served as principal assistant to Mr. Albert Fink on the first bridge across the Ohio at Louisville, and has been closely connected with the Louisville Bridge and Iron Company ever since. In addition to the presidency of this company he held at the time of his death the positions of Chief Engineer of the Henderson Bridge Company and Consulting Engineer of the Louisville and Nashville Railroad system.

A man of warm social temperament and perfect integrity, he was an engineer of absolutely untiring energy and great executive ability. The enterprises with which he was connected and the people among whom he lived will suffer greatly by his death.

IN commenting on the first report of the Ohio State Board of Health we noted the wisdom of trying first to secure a complete registration of vital statistics, and second, the organization of local health authorities.

The State Board of Health of Maine, to judge from its second report for the year 1886, just issued, seems to think the matter of vital statistics hardly worth attending to, and has devoted its energies to the securing the passage of a law, which was approved last March, "to establish local boards of health and to protect the people of this State from contagious disease." This law contains twenty-eight sections and is very stringent in its provisions with relation to small-pox, diphtheria, scarlet fever, cholera, typhus, and typhoid fever, requiring householders and physicians to notify the local board of the existence of all such cases, and establishing a sort of quarantine on the infected premises. "No person having access to any person affected with any of the said diseases shall mingle with the general public until such sanitary precautions as may be prescribed by the local board or attending physician shall have been complied with." We suppose this last clause is intended to exempt the doctor from such precautions. The nurse is forbidden to leave the premises until she, or he, has a certificate of disinfection, etc., and the householder must not allow any property to be removed from his house without permission. We must confess that we do not think highly of this kind of legislation and do not believe that it will be enforced.

When the people of Maine adopt means for knowing promptly the localities in which people are dying too fast they can with profit begin preventive work, and until they have this knowledge it will only be the terror produced by a well-developed epidemic that will induce them to execute the law above referred to.

The second report is made by the Secretary of the Board, Dr. H. G. Young, of Augusta, and, with the appended documents, forms a volume of about 300 pages, which is mainly educational in character. It is to be hoped that under the new law the board may be able to make an original contribution to sanitary science by collecting data as to the hygienic condition of different parts of the State and presenting them in a well-digested report.

PERSONAL.

CAPTAIN W. T. ROSSELL, Corps of Engineers, has moved his office, temporarily, from Memphis to Sewanee, Tenn.

NAVAL CONSTRUCTOR JOHN B. HOOVER, U. S. N. has been ordered to duty relating to vessels to be built by Cramp & Sons.

SENATOR SENEOL, a prominent railroad man, died in Montreal, Can., October 11. He was interested in many railroads and navigation companies.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

PROPOSALS.

(Continued from page 576.)

Removing Wreck at Cornfield Shoal, Long Island Sound.

ENGINEER OFFICE, U. S. ARMY,
Room 57, Army Building, cor. Houston & Greene Sts.,
New York, October 24, 1887.

Sealed proposals, in triplicate, for removing the wreck of the schooner "Louise Bliss," now lying in about three fathoms of water near the west end of Cornfield Shoal, Long Island Sound, will be received at this office until twelve o'clock, noon, on Wednesday, November 23, 1887.

Further information, specifications and forms of proposals can be obtained at this office.

D. C. HOUSTON,
Lieut.-Col. of Engineers.

25
WATER-PIPE.—Proposals will be received until the 4th day of November, to be endorsed "Proposals for Cast-Iron Water-Pipes, Boston Water-Works." 2,000 tons 6-inch pipe, class B; 550 tons 8-inch pipe, class B; 400 tons 12-inch pipe, class A; 1,000 tons 12-inch pipe, class B; 150 tons of special castings. Specifications may be obtained and plans seen at the office of the City Engineer, City Hall, Boston. William H. Smart, Chairman pro. tem. in Boston Water-Board, City Hall, Boston.

For works for which proposals are requested see also the "Proposal Column," pages 569-576.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE ENGINEERING & BUILDING RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

WATER. SEWERAGE. ETC.

MINNEAPOLIS.—Bids for the machinery for the new pumping station will be received for forty days longer by the City Council. All bids so far received will be returned to bidders.

KENDALLVILLE, IND.—The contract has been let for the building of the water-works here. R. D. Wood & Co., of Philadelphia, have the contract for pipe and hydrants; the Knowles Steam-Pump Works for steam-pumps, and James Flower & Bro., valves.

KINSLEY, KAN.—Our correspondent writes: "Contract was let to D. Mitchell & Co., of Dodge City, Kan., and work will be begun immediately. The works will be the stand-pipe system, with compound pumps of 750,000 gallons capacity each. About four miles of main will be laid, works to be completed by January 10, 1888."

GREELEY, COL., October 12.—Our correspondent writes: "The subject of water-works is being agitated, but at present there are more theories than money to build any system. We have either to pipe water thirty miles, with 600 or 700 feet fall for that distance, or sink a caisson fifty or sixty feet, shutting off surface water completely, and drawing from a vein in the same rock, and use Holly or some other system of pumps. We have an elevation of 140 feet about one mile south of centre of the city, where a reservoir could be built for storage and service. That is the standing at present."

CHARLOTTE, N. C.—Mayor F. B. McDowell is dissatisfied with the service of the present water-company. He claims that it is inadequate and the works not what they should be. He says the citizens want a plant that can supply water for 11,000 people, about 140 hydrants, and that the city ought to own its plant, and would like estimates looking toward the building of such works. What rights the present company have to supply water to the town are not stated.

PROPOSALS will be received, until October 24, by City Clerk G. H. Cole, of Toledo, O., for boring artesian wells; also for paving Indiana Avenue.

ORANGEBURG, S. C.—Our correspondent writes: "The city has made arrangements by which a 6-inch pipe will be laid in our town—say about 12 or 14 miles—during the next year or two."

GALT, ONTARIO, CAN.—Our correspondent writes: "We have had the ground surveyed, plan of the streets with location of hydrants made, and our system of water-works completed—viz., to obtain water from Spring Lake, situate three miles from corporation, and pump it into reservoir 210 feet above the city level. The committee have submitted the scheme to the Council, by whom it has been approved. A by-law has been introduced and read a first time and after it receives its second reading will be submitted to a vote of the ratepayers, after which, if the vote be favorable, the work will proceed."

SOUTHBIDGE, MASS.—Our correspondent writes: "The water-works are already established three years. The only change which I know of at present is the enlarging of capacity, which will probably be commenced at a future date."

EAST JORDAN, MICH.—Our correspondent writes: "If talk would build water-works we should have had them ere this, but no official steps have been taken as yet to establish water-works in this place."

RICHFIELD, KAN.—Our correspondent writes: "Nothing has been done toward water-works here as yet, and nothing is contemplated for the present further than the sinking of an artesian well. What that may bring about no one knows. Our town is too young to consider the question of water-works as yet."

ORTONVILLE, MINN.—Our correspondent writes: "Have had our election; result was in favor of bonds; are negotiating same, and expect to complete same this fall."

ESSEX, VT.—Our correspondent writes: "In reply will say that this town has taken no steps whatever in regard to establishing water-works of any kind whatever, and there are none in contemplation to my knowledge."

GREENVILLE, O.—Our correspondent writes: "No election was held; parties withdrew their proposition to build."

WESTFIELD, N. Y.—Our correspondent writes: "Last Saturday, October 15, the voters of the corporation voted to raise \$50,000 for water-works. Further than this I cannot tell what will be done."

GREENVILLE, MICH.—Our correspondent writes: "The electors of the city voted in favor of a loan for water-works on the 10th inst., and the city will put in said works as soon as practicable."

JERSEY CITY, N. J., will advertise for proposals for a supply of pure and fresh water to the city. Address the Board of Works.

CINCINNATI, O.—Special Committee of Council have for consideration a resolution providing for a commission of five on purity of the water-supply.

MODESTO, CAL.—The Turlock Irrigation District voted October 8 on issuing \$600,000 to build a canal. The proposition was carried.

SACRAMENTO, CAL.—The City Engineer has been directed to prepare plans and specifications for a number of pipe and brick sewers.

JERSEY CITY, N. J.—The Jersey City Board of Finance on October 13 refused to approve the Board of Works resolution providing for a contract with the Bartlett Water Company for a water-supply for the city at a cost of \$36.50 per million gallons. It directed that advertisements be inserted inviting proposals for a water-supply.

GENEVA, N. Y.—Citizens are talking of building a main sewer.

SANTA FE, N. M.—Articles of incorporation of an irrigating enterprise in the Central Rio Grande Valley were filed at the office of the Territorial Secretary October 11. The incorporation is to be known as the Albuquerque Land and Water Company. Mr. Gay Robertson, of Kansas City, has been earnestly promoting it for the past year. The enterprise contemplates the irrigation of 1,500,000 acres of the fruit and farming lands in the Central Rio Grande Valley. The water-supply is to come from the Rio Grande. The main canal, according to the survey already completed, will be 150 miles in length.

JERSEY CITY, N. J.—This city and West Hoboken have united in requesting the City Engineer of Jersey City to prepare plans and estimates for a joint sewer along Paterson Avenue.

COLUMBUS, O.—\$8,000 is to be expended on a main sewer in District No. 1.

BUNKER HILL, ILL.—The erection of water-works in this city is being generally discussed. The question will doubtless be early submitted to a popular vote.

STAUNTON, ILL.—Staunton wants a system of water-works, and the Village Board has completed two surveys for reservoirs, one of which, it is estimated, will contain 100,000,000 gallons of water. The building of the dam will cost about \$11,000. No active operations will be commenced this season, however.

OCEAN SPRAY, MASS.—Ocean Spray, Great Head, and Winthrop have held a town meeting on sewerage. The expression of those present was unanimous in its favor.

LOUISVILLE, KY.—The Louisville Water Company has elected directors and officers as follows: Charles R. Long, President; James G. Gilbert, W. W. Smith, J. W. Story, T. L. Burnett, and Leander Reed, Directors; W. P. McDowell, Treasurer; J. B. Collins, Secretary; Charles Hermans, Superintendent and Chief Engineer.

CHILLICOTHE, MO.—An official test of the Chillicothe Water-Works was made October 11. The water is brought from Grand River, two miles distant.

WEST RANDOLPH, VT.—West Randolph is being supplied with water from the new works as fast as the connections with the mains can be made. The cost of the works was \$20,000.

LANCASTER, PA.—The Mayor will receive proposals until October 28 for four steam-boilers, 100 horse-power, of steel, Jarvis settings, for the water-works.

BEVERLY, MASS.—A special town meeting was held October 18 to see what action the town will take to lower the level of Round Pound, in accordance with the petition of the Board of Health, which has declared it a nuisance. Also to see if the town will take any action regarding drainage below Brimball Avenue, between Cabot Street and Kitteredge crossing. An electric-light is also called for.

BAKERSFIELD, CAL.—The Supervisors, October 10, granted a franchise for a water company.

PROVIDENCE, R. I.—Common Council has authorized the Mayor to borrow \$180,000 for purchase of lands for sewage-pumping works.

PASSAIC CITY, N. J.—The Acquackanuk Water Company, which supplies Passaic with water, has passed into the control of Garrett A. Hobart, of Paterson, and John R. Bartlett and others, of the West Milford Water Storage Company. They will supply Passaic with water from other sources.

BOSTON, MASS.—See our Proposals for tenders for water-pipe.

MONTREAL, CAN.—The city will issue proposals for about \$50,000 worth of iron and brass pipe and piping for the water service. Address Mr. Lesage, at the water-works.

CLAYTON, N. Y.—Water-works are to be constructed here. Address the Town Clerk. Immediate attention is necessary.

HOLDRIDGE, NEB.—Address Nels. Nelson about water-works here.

CEDAR FALLS, MICH.—City Council has ordered specifications prepared for water-works. Address the City Clerk.

SAN BERNARDINO, CAL.—The Mountain Water Company has been incorporated; capital stock, \$100,000.

BEVERLY, MASS.—The town has accepted the new water-works. They cost \$139,000. The superintendent is Mr. Pickett.

BATH, N. Y.—The new water-works, built by Bassett Bros., of Buffalo, were tested September 20 and accepted. The engineer is William E. Howell.

MOUNT CARMEL, ILL.—The Mount Carmel Development Company has been incorporated by Robert Bell and others, to construct a canal to supply water.

WARE, MASS.—The new system of sewerage is now being surveyed.

WESTBORO, MASS.—Our correspondent writes: "Our water-works were established in 1878, and have been in successful operation since. The town voted this season to improve the reservoir, and have expended about \$10,000 so far. It is estimated that the improvements will cost \$5,000 or \$6,000 more."

GREENVILLE, MICH., voted, October 10, to have water-works; estimated cost, \$25,000.

SPRINGFIELD, ILL.—This city, previously noted, has appointed a committee of five to confer with the Water Commissioners on propositions already submitted for increasing the water-supply.

RAHWAY, N. J.—The Pennsylvania Railroad will have its own water-supply, laying mains to the Rahway River and pumping into tanks at Scott Avenue.

ST. JOHNSLAND, L. I.—The Board of Commissioners of Charities and Corrections has sent to the Supervisors of Kings County plans and specifications for water-supply, including pumping-engines, sewers, and roads; estimated cost, \$360,000. William H. Ray, of Brooklyn, is President of the Board of Commissioners.

TORONTO, CAN.—William Hamilton, Superintendent of Water-Works, reports that "a plan for the enlargement of these works has not been decided upon. I have recommended a 4-foot cast-iron flexible-joint pipe, with an 8-million pumping-engine. The pipe will be about 10,000 feet long."

GAS AND ELECTRIC-LIGHTING.

AUGUSTA, GEO.—The Augusta Gas-Light Company are extending their plant.

COLUMBUS, GEO.—A permit to erect an electric-light and power plant in this city has been applied for by Messrs. T. E. Blanchard, Amory Dexter, and E. H. Jenkins.

McKEESPORT, PA.—The Electric-Light Company has enlarged its electric-light plant from 3,000 to 4,000 lights.

PORTLAND, ME.—Petitions from the Consolidated Electric-Light Company and the Portland Light and Power Company to furnish electric-lights are before City Council.

PORTLAND, ME.—Electric lights will be placed on Portland Bridge.

GARRETTSVILLE, O.—C. M. Udal contracts to maintain electric street lights for \$450 per annum.

CHICAGO.—Address Professor Barrett, City Electrician, in regard to electric-light system for the streets. The city has a committee to obtain cost of plants. Immediate attention is necessary.

ST. CLOUD, MINN.—The Electric-Light Company will have a 450-light tower ready for use within 30 days.

SEWARD, NEB.—The city will have electric lights in the streets.

TROY, N. Y.—The Union Railroad Company has contracted with the Edison Electric-Light Company to light and heat the union depot. The cost of the plant is estimated at about \$30,000. The Edison incandescent system will be used.

PEORIA, ILL.—Incorporated is the Peoria Heat, Light, and Power Company, of Peoria, Ill.; furnish heat by steam and light by electricity. Incorporators: Joseph B. Smith, Eliot Callender, S. H. Thompson, R. S. McDonald.

ROCKVILLE, CONN.—The gas company is negotiating for the introduction of the Sawyer-Mann electric-light.

CLEVELAND, OHIO.—The Bellevue, Ky., Natural-Gas Company is asking for permission to establish a gas-plant and lay mains.

UTICA, N. Y., is advertising for gas and electric street-lights. Until October 28. Address the City Clerk.

ORANGE, N. J.—The Edison Illuminating Company, which was recently incorporated for the purpose of establishing an electric light, heat, and power plant in the Oranges, organized October 11 as follows: President, Gilbert R. Hayes; Vice-President, Thomas A. Edison; Secretary, Eugene S. Kass; Treasurer, George Spottiswoode.

MEXICO, N. Y.—Articles of incorporation of the Mexico Electric Light and Power Company have been filed to furnish heat to manufacture electric-light, both arc and incandescent. The capital stock is \$8,000, and the trustees are William H. Weed, Edwin L. Huntington, and S. L. Alexander.

PATERSON, N. J.—The Paterson Electric-Light Company will establish the incandescent-light system, and supply houses and business places all over the city.

PHILADELPHIA.—The Royal Gas Company, of Philadelphia, has been merged with the Washington Gas Company. The capital of the new concern is \$1,700,000, and the new company will be known as the Royal Gas Company. The President is William P. Logan.

BALTIMORE, CONN.—gas-works were destroyed by fire October 14. They will be rebuilt.

JAMAICA, L. I.—The Village Trustees have awarded the contract for street-lighting to the Jamaica Gas-Light Company.

ST. LOUIS, MICH.—will have electric street-lighting.

LOUISVILLE, KY.—There is a movement in Councils that the city buy the works and franchise of the Louisville Gas Company. Address L. N. Demlitz, office of City Attorney.

PHILADELPHIA.—The sole transfer of the franchises and property of the Balducci Natural-Gas Company to a company of Philadelphia capitalists, represented by a New York broker, is announced.

MCDONALD, PA.—A natural-gas plant will be developed here and works built for Edney Coal Mining Machine Company.

BAKERSFIELD, CAL.—A franchise for an electric-light company has been granted.

GREAT BARRINGTON, MASS.—A meeting was held Thursday evening to take action regarding the formation of a stock company for supplying the town with light. P. A. Russell, the President of the Berkshire Woolen Company, has prepared the following estimate: Number of lights now in use, 240; probable increase, 70; total yearly receipts, \$4,000; total expense, \$2,330. A dynamo and moving would cost from \$6,000 to \$6,500.

ST. CLOUD, MINN.—An electric-light plant for street-lighting will be established here.

FLORENCE, ALA.—will have electric street lights. The plant will be completed by December 15.

CHEYENNE, WYO.—The Standard Gas Company, capital \$100,000, has been incorporated in Cheyenne. One of the incorporators is Bob Ingersoll, of New York.

BUFFALO, WYO.—will have electric-lamps for street-lighting.

HOOSICK FALLS, N. Y.—has contracted with Hon. S. D. Locke to light the streets with electric-lamps.

EAST ORANGE, N. J.—Articles of incorporation of the Columbia Light and Power Company have been recorded. The object of the company is to furnish electricity for lighting, heating, and power. The principal place of business is East Orange.

GRASS VALLEY, CAL.—On October 13, the question of lighting the streets with gas or with electricity was before the Town Trustees. A committee has gone to Nevada City to study the electric-lights there.

ST. ALBANS, VT.—An electric-light plant will be erected here.

ROANOKE CITY, VA.—Abstract of bids for erecting an electric-light plant, opened October 10: American Electric-Light Company, Nashville, Tenn., \$18,550; Thomson-Houston Electric-Light Company, Boston, Mass., \$22,125; Cecil P. Poole, Lynchburg, Va., \$26,200.

UTICA, N. Y.—City Council is asking for bids on street lighting. Address the City Clerk. Immediate attention is necessary.

ASHANAY, R. I.—Money has been raised to light the streets.

WESTON, W. VA.—will erect an electric-light plant.

SPOKANE FALLS, WYO.—wants proposals for erecting an electric-light plant (1,800 incandescent and some arc lights). Immediate attention is necessary.

MEMPHIS, TENN.—The Equitable Gas-Light Company has been incorporated, with capital of \$750,000 cash, paid up. They have purchased location for their works, and will build works. W. H. Katzenberger is President, P. G. Goodhart is Vice-President.

DAYTON, TENN.—W. G. Allen and others will erect an electric-light plant.

ANNISTON, ALA.—Address the Anniston City Land Company in regard to establishing an electric-light plant here.

MINNEAPOLIS.—The Court-House Commission has awarded contract for electric-lighting the new court-house and city hall to the Edison Electric Light and Power Co. at \$3,000 per year. Other bids were: United States Electric-Light Co., two bids, one \$3,600, one \$3,400; the Thomson-Houston Electric-Light Co., \$4,988.

GRAND FORKS, DAK.—New gas-works are building here.

PITTSBURG, PA.—A company has been formed to supply the district on the South Side hilltops with incandescent lights.

EDWARDSVILLE, ILL.—The City Council has contracted with E. W. Mudge, of this city, to light the streets with 2,000 candle power electric-lights, the franchise to continue five years. Fourteen lights were located by the Council, to be furnished at an annual rental of \$108 each, and all additional lights to be supplied at \$100 each.

TRINIDAD, COL.—The Trinidad Electric-Light Co., capital stock \$25,000.

SPRINGFIELD, ILL.—Niagara Light and Fuel Company, at Chicago; capital stock, \$1,000,000; incorporators, Edgar L. Hance, Alfred E. Barr, and Samuel Kerr.

STEAM-HEATING, BUILDINGS, ETC.

SACRAMENTO, CAL.—Lawson & Co. were awarded a contract to supply jute machinery for \$106,851.55, for the prison.

TORONTO, CAN.—Architect Lennox has prepared plans for the court-house and city hall. The plans have been referred to Mr. Matthew Sheard, to report upon them.

NEWARK, N. J.—The Boston Super-Heated Water Company has an application before City Council for a permit to lay mains and supply heat to buildings.

WARREN, O.—The steam-heating contract for the new Park Hotel has been awarded to Schell, Sample & Co., the lowest bidders.

OMAHA, NEB.—All bids for constructing the City Hall have been rejected and new proposals advertised. Address the Board of Public Works.

AUGUSTA, GEO.—Address A. H. Davidson, City Engineer, with proposals for building a warehouse and wharf.

CROMWELL, CONN.—has voted to build a Town Hall.

NEW YORK CITY.—The Board of Education has made a requisition on the Comptroller to issue \$600,000 of bonds at once for new school houses.

BRIDGES.

ROME, GEO.—See our Proposals for a reference to a bridge over the Oostonaula River.

ELIZABETH, PA.—Our correspondent writes: "Company organized and officers elected for Elizabeth Bridge Company; \$40,000 stock subscribed. The company mean business. The bridge will be built over the Monongahela River at this place. President Bridge Company, W. W. O'Neil; Secretary, P. T. B. Shaffer; Treasurer, William D. O'Neil."

MECHANICSVILLE, N. Y.—Our correspondent writes that "the bridge company has organized with the following officers: W. W. Smith, President; J. F. Terry, Secretary, and has made a preliminary survey of the river for a site, but has not yet decided where to locate it."

HARRISBURG, PA.—Our correspondent writes in reference to bridges: "The Pennsylvania Railroad Company has presented plans and propositions to erect overhead bridges in our city over Mulberry, Race, and Dock Streets, which were considered in Com-

mon Council and referred to the Committee on Highways, which Committee have not yet reported on the same."

NORTHAMPTON, MASS.—Our correspondent writes: "No action has yet been taken, but the matter of constructing a bridge over N. H. & N. Co.'s road and Mill River, to take place of covered wooden bridge, and South Street grade crossing, will be considered as soon as the N. H. & N. Co. present their plans and recommendations."

SALEM, MASS.—The Boston and Maine Railroad has a new drawbridge over the Mystic River, built by Joseph Ross, of Ipswich.

OHIO BRIDGES.—The Bellaire, Zanesville and Cincinnati Railroad Company, Ohio, is building ten new bridges.

FORTRESS MONROE.—The Groton, N. Y., Bridge Company has secured the contract for building the pier here. Over 500 tons of iron castings are called for in the estimate.

GREEN BAY, WIS.—It is proposed to build a drawbridge on line of Walnut Street, to cost \$10,000, and repair Mason Street bridge at considerable expense.

BRIDGE.—Detailed estimates for a bridge over the English Channel have recently been laid before the French Minister of Public Works by Vice-Admiral Cloué, of the French Navy, in the hope of obtaining a Government subvention for the project. The cost of the bridge is estimated at \$22,000,000.

NEWARK, N. J.—Committees of citizens of the Eighth Ward and the township of Kearney advocate the construction of a free bridge across the Passaic to connect Kearney with Newark. The Board of Freeholders appointed a committee of five to confer with a similar committee of the Hudson County freeholders on the subject.

LAREDO, TEX.—City Council has decided to grant a franchise to the Ornelas Bridge Company to build a street-railway bridge across the Rio Grande, on condition that the city receive \$5,000 per annum for twenty-five years. The bridge company is given thirty days in which to accept or reject the proposition.

TRENTON, N. J.—In regard to prospects of a new bridge over the Delaware River, our correspondent writes: "None whatever; we have two, one used by the Pennsylvania Railroad Co., and the other a private company stock corporation."

POTTSVILLE, SCHUYLKILL CO., PA.—The following bids for building an iron bridge in Tremont Borough, Pa., were received by the County Commissioners, October 11:

Tippett & Wood, Phillipsburg, N. J., \$735.
John W. Berry, Pittston, Pa., \$410.
Penn Bridge Co., Beaver Falls, Pa., \$765.
King Iron Bridge and M'f'g Co., Cleveland, O., \$768.
Nelson & Buchanan, Chambersburg, Pa., \$774.
Morse Bridge Co., Youngstown, O., \$825.
Wrought Iron Bridge Co., F. W. Finly, Carlisle, Pa., \$723.
Berlin Iron Bridge Co., Binghamton, N. Y., \$795.
Contract was awarded to Penn. Bridge Co., October 17.

BRIDGE.—See our Proposals for reference to a bridge over the Maumee River, O.

DULUTH, MINN.—A project is started to bridge the canal.

FORT SCOTT, KAN.—The Kansas City Bridge Company has the contract for a bridge over Mill Creek. Address F. L. Underwood.

PASO ROBLES, CAL.—Blackburn Bros. & James will build a bridge over the Salinas River.

CLEVELAND, O.—Plans for a bridge on Fairmount Avenue, over Nickel-Plate Railroad, are nearly ready. Address City Engineer Rice.

ROME, N. Y.—Bids for constructing an iron bridge across Wood's Creek, near Patrick's, were recently opened by the Commissioners of Rome and Verona, as follows: Groton Iron Bridge Company, \$1,640; Smith Company, \$1,675; Smith Company (second bid), \$1,750; Berlin Company, \$1,610; King Company, \$1,624; Morse Company, \$1,595; Penn Company, \$1,600; Wrought Iron Bridge Company, of Canton, O., \$1,550. The contract was let to the last-named company, their bid being the lowest.

JACKSONPORT, ARK.—Address the County Court in regard to bridges to be built over the Cache and the White Rivers.

STREET WORK AND PAVING.

LITTLE ROCK, ARK.—Bids are called for up till October 25, for 11 blocks of Telford macadam pavement by the Commissioners of Pavement District No. 2: Sidewalk District No. 3 will put down about 1½ miles of sidewalk and curbing on East Fifth Street; Sidewalk District No. 5 has been organized for the purpose of building sidewalks and laying curb on Cumberland Street, about 1½ miles. For information address the City Engineer.

NEW YORK CITY.—The Board of Estimate and Apportionment has appropriated \$250,000 for the improvement of Morningside Park.

DULUTH, MINN.—Improvements on 12th and Michigan Streets are ordered.

PITTSBURG, PA.—Address E. M. Bigelow, City Engineer, on street and sewer work ordered by Council.

CAMBRIDGE, MASS.—The extension of Windsor Street is under consideration; estimate, \$7,000.

PROVIDENCE, R. I.—Much grading and granite paving was ordered by the Common Council at the meeting October 17. Address the Clerk of Council.

PROVIDENCE, R. I.—Council has passed an order for the improvement of Brown Street; cost \$9,340.

ROCHESTER, N. Y.—City Council has ordered Kirk Street extended to Union Street.

ROCHESTER, N. Y.—Address the City Clerk in regard to street work and extension.

NEWARK, N. J.—Address the Mayor in regard to much street work which is now ordered to be done.

ST. PAUL.—The order for grading Winslow Avenue at an estimated expense of \$18,713 was favorably reported to the Board of Public Works.

MILWAUKEE.—Plans are being prepared for the new public park in the Eighth Ward. There will be an artificial lake and a rustic bridge over it.

OMAHA, NEB.—The Board of Public Works has let the contracts for grading part of Jones Street to Fitch & Co. at 17½c. per cubic yard; Howard Street to G. W. McKinney at 20c. per cubic yard; Seventeenth Avenue to Fitch & Co. at 19c. per cubic yard; Grace Street to G. W. McKinney at 16c. per cubic yard.

ST. PAUL, MINN.—Our correspondent writes: "The public work done in this city during 1887 has been unprecedented. It may be summarized as follows: Miles of street grading, 69; miles of paving, 11; miles of sewers, 15; miles of wooden sidewalk, 55. In addition to the wooden sidewalks a large amount of artificial stone walk has been laid, three firms in St. Paul who manufacture it having been crowded all the season. The cost of the work has been approximated as follows: Paving, \$422,115; sewers, \$289,136; grading, \$988,375; bridges, \$200,000; total, \$1,902,627."

TARRYTOWN, N. Y.—It is stated that \$20,000 will be expended for street improvements. Address the Village Clerk.

RAILROADS, CANALS, ETC.

ALLEGAN, MICH.—Over \$30,000—half the amount—to begin the construction of the C. J. & M. R. R. has been subscribed, and work will likely begin late in the fall.

ALBANY, N. Y.—The Caldwell and Bolton Turnpike Road Company has been organized with the following officers: President, George H. Cramer, Troy; Vice-President, W. Sherman, Glens Falls; Secretary, Robert Imrie, Caldwell. The object is to build a boulevard along the shore of Lake George from Bolton to Caldwell.

CHICAGO.—Incorporated is the National Gas Car Heating and Lighting Company at Chicago. Incorporators, Harry W. Holmes, Lewis K. Curlett, and William S. Brewster.

RAILROAD.—The contract for building a railroad into the San Jacinto Valley by the California Central Railroad Company has been signed. J. A. Green, James Kerr, and H. C. Ashenfelter signed for the people of San Jacinto, and F. T. Perris for the California Central.

DULUTH.—Shepherd & Winston, contractors, of Minneapolis, have secured contract for the 30-mile extension of the Duluth and Iron Range Railroad. Construction is to be completed by April next.

HAMMOND, ILL.—A charter has been granted to a street railway company here.

MINNEAPOLIS.—To Henry & Balch, of Minneapolis, the Milwaukee, L. S., and Western R. R. Co. awarded contract October 10 to grade 40 miles of road-bed from Rhinelander, northwest through the woods. The same company have let the contract for grading an extension of 6½ miles from Hurley south-west to the farm of Henry & Balch.

HARRISBURG, PA.—A charter has been issued to the Squirrel Hill Railroad Company of Allegheny County.

FRANKLIN, MASS., October 11.—A party of men are surveying a route for the New York and Boston Rapid Transit Company through South Wrentham.

LOS ANGELES, CAL.—The Santa Monica Outlook Railroad Company has been organized. The officers elected for the following year are: Abbot Kinney, President; Patrick Robertson, of Scotland, Vice-President, and James Bettner, of Riverside, Secretary and Treasurer.

SALIDA, COL.—Land-Agent Hastings has received the right of way for an extension of the Denver and Rio Grande from Poncha Hot Springs through the San Luis Valley. The road will be extended to Seguche and Del Norte.

NEVADA COUNTY, CAL.—It is proposed to form a joint stock company and sink a well 2,000 feet if necessary. A capital of \$2,500 will be subscribed.

The Board of Supervisors of Nevada County have received a petition from the Nevada County Land Association, asking to be granted a franchise to construct an electric railway from Nevada City four miles along the county road.

KNOXVILLE, TENN.—The survey of the Belt Road has been completed and the engineers are now making the profiles. These profiles and estimates will be completed in a few days, when it is understood the entire line will be let to contract.

SIoux CITY, IA.—Address John Peirce, of Peirce's Addition, about a \$90,000 contract for grading, etc., for a cable railway.

ROCK ISLAND, ILL.—Incorporated is the Elm Street Railway Company, at Rock Island; incorporators William McEniry, John J. Reimers, W. P. Quayle, Will R. Johnson, and Will J. Whitehead.

MERIDIAN, MISS.—Dunn Bros., the contractors to build the Warrior Coal Field Railroad from Meridian to Gainesville, Ala., broke dirt on this end October 15, just inside of the city limits. They are under contract to prepare the bed for the rails within six months.

BAKERSFIELD, CAL., has granted a franchise for a street railway.

ELIZABETH, N. J.—On October 24 Council will give a hearing to all parties interested in electric-motor street railways. A report will be discussed, from committee, favoring the granting of a franchise to the Union Electric Railway Company.

EAST SAGINAW, MICH.—The Toledo, Saginaw and Mackinaw Railroad Company has let the contract very recently for the construction of the road between East Saginaw and Durand, a distance of forty-five miles, to McRae, Lally & Son, of Detroit. The contract calls for the completion of the road by July 1, 1888.

NEW YORK CITY.—The Arcade Railway directors for the following year are: Ex-Judge Charles P. Daly, Melville C. Smith, George S. Coe, Jerome Fassler, Alfred M. Hoyt, Cornelius J. Ryan, William Windom, Benjamin F. Dunning, Arthur B. Claflin, George W. Lyon, Henry Sanford, Ex-Senator Edward B. Thomas, and James F. Pierce. It is claimed contracts will be let in thirty days.

CHICAGO.—Incorporated is the Chicago Transfer Railroad Company. Capital stock, \$2,000,000. It is proposed to construct a railway from a point in the Town of Proviso, Cook County, Ill., to an intersection with the Chicago, Rock Island and Pacific Railway in the Town of Orland, Cook County, Ill. Incorporators, Ansen Oppenheimer and others.

ST. PAUL.—Ramsey and Hennepin County Commissioners have let contract for Marshall Avenue and Lake Street bridge as follows:

For the substructure, to P. P. O'Halloran, to use Kettle River stone, \$33,136.96; for the superstructure, to the Canton Wrought-Iron Bridge Company, of Canton, O., for \$109,100.

BIDS OPENED.

LAKE, ILL.—Bids for furnishing pumping-engines were opened by the Board of Trustees October 4, as follows:

Holly Manufacturing Company, Lockport, N. Y.: At 68th Street station, 1 No. 8 pumping-engine (4 boilers), 12,000,000 daily, duty 95,000,000 at ¾-capacity and 105,000,000 at full capacity, \$58,500, including boiler foundations and settings, but not engine foundations. At 59th Street station, 16,000,000 gallons daily, No. 9 pumping-engine (6 boilers), duty 95,000,000 at ¾-capacity and 105,000,000 at full capacity, \$89,400, including boiler foundations and settings, but not engine foundations; or a No. 8 engine, duty 95,000,000 at ¾-capacity, or 105,000,000 at full capacity, \$58,500, including boiler foundations and settings, but not engine foundations. If two 12,000,000-gallon pumping-engines are selected, with 6 boilers, deduct \$2,000 for boilers omitted.

Henry R. Worthington: At the 68th Street station, 12,000,000 gallons, 2 engines, 6,000,000 each, including foundation, \$51,100, 7 boilers, including foundation, \$17,200, total, \$68,300; 2 engines, 6,000,000 each, exclusive of foundation, \$48,500, 7 boilers, exclusive of foundation, \$16,100, total, \$64,600; guaranteed duty, 100 million. At the 59th Street station, 16,000,000 pump, 2 engines, 8,000,000 each; 2 engines, 8,000,000 each, including foundation, \$58,000, 10 boilers, including foundation, \$23,850, total, \$81,850; 2 engines, 8,000,000 each, exclusive of foundation, \$55,500, 10 boilers, exclusive of foundation, \$22,600, total, \$78,100; guaranteed duty, 100 million. At the 59th Street station, 12,000,000 pump, 2 engines, 6,000,000 each, including foundation, \$50,500, 8 boilers, including foundation, \$19,200, total, \$69,700; 2 engines, 6,000,000 each, exclusive of foundation, \$48,500, 8 boilers, exclusive of foundation, \$18,200, total, \$66,700; guaranteed duty, 100 million.

SAN FRANCISCO, CAL.—The following bids for building a pier 534x100 feet in 20 to 35 feet of water, and a freight-shed 520x90 feet, were received by Board of Harbor Commissioners, October 7:

George W. Davis, San Francisco, informal. R. W. McCann, San Francisco, \$37,980.23; check informal.

American Bridge and Building Co., San Francisco, \$38,943.

James G. McMahon, San Francisco, \$39,850.

San Francisco Bridge Co., \$40,937.

R. McKilliken, \$41,400.

All bids were rejected; proposals will be re-advertised. Marsden Manson is Chief Engineer.

LANCASTER, PA.—The Special Committee of City Councils on Water-Works, Sewerage and Drainage opened the bids for the water-works October 13 as follows:

John A. Burger proposed to erect the buildings for \$28,387, with granite base for engine and boiler house and stack; or, for \$27,247, if the bases be of brick.

R. A. Malone and Thomas C. Wiley, the work in full, for \$29,750.

Amos S. Urban, the work according to plans and specifications, for \$24,450.

John Evans & Son, to build complete the water-works for \$24,900.

The following bids were informal and were not considered:

George Ernst, Jr., bid \$24,550.28.

McLaughlin & Gesell bid \$35,000.

I. P. Mayer bid \$23,800.

The contract was awarded to Amos S. Urban for \$24,450. Mayor Morton was authorized by the committee to sign the contract on behalf of the city. The work must be finished by February 1, failing in which \$15 per day for all time over that date will be forfeited.

The Warren Foundry & Machine Company accepts the award for furnishing the more than 5,000 feet of pipes required for the main leading from the water-works to the reservoir.

PENSACOLA, FLA.—At a meeting of the City Commissioners October 11 bids for the erection of a public building were opened as follows:

B. R. Pitt, \$33,000; R. H. Turner, \$37,590; A. V. Clubbs, \$24,000.

LINCOLN, NEB.—The following bids for water-works, Pawnee City, Neb., and Long Pine, Neb., have been received by A. A. Richardson, C. E., of Lincoln:

Charles Schroeder, Columbus, Neb., total work without wells, \$25,125 for Pawnee City.

H. F. Cook & Son, Omaha, Neb., with wells, \$2,500 for Pawnee City.

S. K. Felton, Omaha, Neb., total work for Long Pine, Neb., \$7,000.

CINCINNATI, O.—Bids on supplies for public building have been opened by the Committee as follows: Plumbing—Thomas J. O'Hara, \$929; The Gibson Co., \$895; J. G. Murdock & Co., \$825; Murphy & Atkinson, \$962; George Eichert, \$898. Awarded to Murdock, seven voting for Murdock, one for Eichert, and one for Gibson.

Carpets—Shillito & Co., Alms & Doepeke. Awarded to Shillito & Co.

Frescoing—Pedretti, three bids, according to quality of work, \$720, \$600, and \$500. Fehrenbruck & Engel, two bids, \$400, \$450. Pedretti's bid included painting, graining, etc., of woodwork. The award was made to them at \$450.

Chairs to the Robert Mitchell Company, "Delawares," at \$1.75 each.

PHILADELPHIA.—Bids were opened at the Board of Education for the following work: Additions to heating Lynd School House, 20th Section, A. H. Lanning, \$140; M. McManus, \$120. The latter was awarded contract.

For heating and ventilating new school-house, Adams and Lafayette Streets, 22d Section, the bids were: A. H. Lanning, \$805; J. Bartlett's Sons, \$1,050; M. McManus, \$945. Lanning received contract.

For heating and ventilating Morris City School the bids were: A. H. Lanning, \$560; J. Bartlett's Sons, \$650; McManus, \$615. Lanning was awarded the work.

NEW YORK CITY.—Bids were opened at the Department of Docks on October 14 for preparing for and building a new wooden pier near the foot of Charlton Street, North River, to be known as Pier, New 37, North River. The following were the bidders: Pacific Improvement Co., \$59,500; William P. Kelly, \$72,000; T. & A. Walsh, \$67,000; J. Eugene Wright, \$71,000; P. Sanford Ross, \$64,490; John Gillies, \$63,000.

NEW YORK CITY.—Bids were opened at the Department of Public Works, October 20, for furnishing and setting a new steam boiler for the Seventh District Court-House, Fifty-seventh Street. The following were the bidders: P. Carraher, \$983; J. Jamer, \$1,221.

NEW YORK CITY.—Bids were opened at the Department of Public Works, October 20, for building a sewer in Ninety-first Street, between First and Second Avenues. The specification called for 755 lin. feet sewer, 500 cubic yards of rock excavation, and 5,000 feet, B. M., timber. The following were the bidders: J. P. Kerrigan, \$7,435; P. Larney, \$10,757.50; T. A. Smith, \$7,655.75; P. Reilly, \$8,064.75.

CHAUTAUQUA, N. Y.—The following proposals for dredging the outlet of Chautauqua Lake have been received by James Shanahan, Superintendent of Public Works, Albany, N. Y.: Willard Johnson, Fulton, N. Y., 21½¢ per cubic yard; E. A. Burroughs, Jamestown, N. Y., 24¢; Ross & Sanford, New York, 27¢; Kingston & Woods, Buffalo, 28¢; Grace & Stratton, Pittsburg, \$1. The contract was awarded to Willard Johnson.

MILWAUKEE, WIS.—Abstract of bids for constructing brick sewers in North Avenue, West Sewerage District, opened October 11: James Markey, 91 feet of 72-inch, \$14 per foot; 55 feet of 48-inch, \$12.60 per foot; 245 feet of 42-inch, \$12.25.

John S. O'Neil, \$16, \$15, \$15.

William Forrestal, \$15.85, \$14.75, \$13.75.

John O'Neill, \$16.75, \$14.25, \$13.50.

John C. F. Brand, \$15, \$15, \$15.

It is worthy of note that James Markey is putting in a 72-inch sewer in Brown Street for \$7.23 per foot. The board has refused to let the contract for North Avenue.

MILWAUKEE, WIS.—Abstract of bids for sewer in Fowler Street: William Forrestal, \$11 per lineal foot; John O'Neill, \$12; John C. F. Brand, \$8.75; Henry Vogt, \$8.70; Charles Brandt, \$8.65; James O'Donnell, \$8.39.

MILWAUKEE, WIS.—The contract for building a sewer in Bismarck Avenue was let to Thomas Morrissey at \$5.80 per foot for brick, and \$2.40 per foot for pipe-sewer.

NEW HAVEN, CONN.—The following bids for constructing pile and timber foundation (3,500 lineal feet) for sewers were received by Albert B. Hill, City Engineer, October 19:

William E. Alling, New Haven, Conn., \$7.90 per foot.

A. Brazos & Sons, Middlefield, Conn., \$7.90.

John & George H. Cavanagh, Boston, Mass., \$7.

C. R. Waterhouse, Jr., New Haven, Conn., \$6.45.

Laurence O'Brien, New Haven, Conn., \$6.25.

Bruen & Shepard, New Haven, Conn., \$6.13. Awarded the contract.

MILWAUKEE, WIS.—For sewer in the South Sewerage District:

BIDDERS.	Price per lineal foot.			
	700 ft. of 36" sewer.	422 ft. of 30" sewer.	135 ft. of 15" sewer.	184 ft. of 12" sewer.
John O'Neil	\$7.30	\$6.80	\$1.99	\$1.90
J. C. F. Brand	6.00	4.90	1.70	1.50
John S. O'Neil	6.00	4.75	1.80	1.40
Patrick Drew	5.83	5.40	2.23	1.80
Henry Vogt	4.30	3.35	1.65	1.45

The contract was let to Henry Vogt, October 14.

FOND DU LAC.—Bids for constructing a bridge at Arndt Street were opened October 3, as below:

E. A. Spalding, Dubuque, Iowa, \$710.

King Iron Bridge and Manufacturing Co., Cleveland, O., \$1,075, with iron piers.

Kansas City Bridge and Iron Co., four plans—plan A, \$695; B, \$689; C, \$635; D, \$600.

Wisconsin Bridge and Iron Co., two plans—A, \$630; B, \$590.

Groton Bridge and Mfg Co., four plans—plan A, \$585; B, \$700; C, \$780; D, \$875. The three latter plans contemplate iron joists.

A. Y. Bayne & Co., Minneapolis, three plans designated by weight, at \$600, \$645, and \$695.

Massillon Bridge Co., Massillon, O., two plans—No. 1, \$550; No. 2, \$580.

Wrought Iron Bridge Co., Canton, O., four plans—A, \$625; B, \$567; C, \$500; D, \$465.

Milwaukee Bridge and Iron-Works, presents two plans, both same price, \$620.

P. E. Lane, Chicago, \$675.

PETERSBURG, ILL.—The contract for constructing water-works has been given to D. Fisher; cost of works, \$20,000.

GOVERNMENT WORK.

HOT SPRINGS, ARK.—No award will be made upon bids for "officers' quarters" received the 29th ult., and the award for the "elevator" upon bids received the 5th inst. is in abeyance.

NORTH HAVEN, CONN.—School bldg in Fourth District.

BRIDGEPORT, CONN.—Robert Houston is to build a house on Main st, near South av, from the plans of Longstaff & Hurd; cost, \$3,500.

Two old-style cottage houses in Park place are to be transformed into houses of modern design, from the plans of Longstaff & Hurd. P. T. Barnum is the owner.

Longstaff & Hurd have made plans for a residence to be erected at Seaside Park by Sherman Hubbard; cost, \$12,000.

Estimates are now being received for the erection of a house on Clinton av, near North av, for S. H. Patterson, from the plans of Henry A Lambert.

BALTIMORE, MD.—Green nr Lexington, 4-story br warehouse; o, A Roseta.

Cor Preston and Hunter al, 4 3-story bldgs; o, C H Callis.

Cor Biddle and Hunter al, 4 3-story br bldgs; o, C H Callis.

Cor Lombard and Ance, 3-story br bldg; o, N R Gill.

Pratt nr Charles, 5-story br warehouse; o, Jas D Mason.

Pratt nr Charles, 4-story br warehouse; o, Jas D Mason.

Pratt nr Charles, 4-story br warehouse; o, Lebrandt-McDowell Stove Co.

Monument nr Anne, 2 3-story br bldgs; o, H L Franz.

Central av nr Mullikin st, 3 3-story br bldgs; o, Fred Hausler.

LANDSDOWNE, IOWA.—First Presbyterian Church.

DAYTON, O.—Government bldg here on Main and Fifth sts.

ATHENS, ALA.—Dwell; o, Judge Horton; contracts let.

KANSAS CITY.—13th and Central, stone church; cost, \$117,000; o, Grace Episcopal Church Society; a, A Van Brunt.

1216-18 Grand av, stone and br store; cost, \$30,000; o, T H Prest; a, Knox & Guinotti.

Kansas av, bet 13th and 14th, pyramida; cost, \$7,000; o, Craig & Hamilton.

Holmes, cor 10th, 3 story br dwell; cost, \$15,000; o, L Bacon.

Vine, cor 18th, 3 story br store; cost, \$10,000; o, Lieberman & Oppenheimer; a, S E Chamberlain.

Frost av, cor 17th, 4 story block dwells; cost, \$15,000; o and a, same as last.

116 bldgs costing less than \$7,000.

ST PAUL, MINN.—7th, cor Arcade, 2-story fr stores and dwell; cost, \$14,000; o, H F Stock.

58 minor permits \$51,000.

JAMESTOWN, N Y.—New Kent House bldg; cost, \$200,000; o, B L Wood, Jr., of Pittsburg; landlords, Shuey & Frisbie.

LEWISTON, ME.—Architect Coombs, of this city, has prepared plans for the Observatory of Bates College.

HARTFORD, CONN.—Bldg for Hartford Electric-Light Co.

DARIEN, CONN.—Methodist Church in progress.

GEORGETOWN, TEX.—Br bldg; o, Capt. Emzy Taylor.

WORCESTER, MASS.—Alt to City Hospital; a, Barker & Nourse.

PUEBLO, COL.—Union depot; cost, \$150,000.

ST. PAUL, MINN.—Theatre on Cedar Street; cost, \$200,000.

DULUTH, MINN.—E A McNair, of Lewis & McNair, agent of the Equitable Life Insurance Company, of New York, says the company will erect on Superior st a \$300,000 bldg.

SPRINGFIELD, MASS.—Willow st, 4-story br block; cost, \$24,000; o, Taylor & Topley; a, J Perkins; b, C W Shattuck and J S Sanderson.

McKNIGHTVILLE, MASS.—The Messrs J D & W H McKnight have under different stages of erection 16 cottages, some of wood and some of brick and wood, ranging in price from \$2,500 to \$15,000.

PROVIDENCE, R I.—Nothing over \$7,000 this week.

15 permits less than \$7,000.

ARLINGTON, MASS.—Fr dwell for Rev Richard Tolman; cost, \$5,000; b, O B Marston; a, E J Lewis, Jr., Boston.

BUILDING INTELLIGENCE.

ABINGTON, MASS.—A new depot will be built here.

ABILENE, KAN.—A \$15,000 city hall here.

PHILADELPHIA.—Hope Presbyterian Church, 38th and Wharton sts, in progress.

LINCOLN, NEB.—The contract for the erection of the industrial college building on the university campus at Lincoln has been let for \$41,000.

LOS ANGELES, CAL.—Griffith blk on Hill st; o, J M Griffith.

BEAVER CITY, NEB.—\$12,000 court-house here.

PITTSBURG, PA.—2 new school bldgs at Ingram and at Sheridan.

CEDAR RAPIDS, MICH.—Bld for Electric-Light Co. on D av.

WALTHAM, MASS.—In progress bldg for A O U W; F. Jarvis, President.

NORRISTOWN, PA.—New school bldg at the west end. Address Board of Education.

BEDFORD, MASS.—Catholics have purchased a lot at the south end of the city, on which to erect a church and parochial school building for the benefit of the French population.

DULUTH, MINN.—The Land and River Improvement Company has received the plans for a new \$80,000 hotel at West Superior. The substructure will be put in this fall.

BLACK RIVER FALLS, WIS.—A stock company will erect a large steam flouring mill.

MINNEAPOLIS.—O F Buell will build a \$75,000 br, stone, and terra cotta ten blk at the cor of Nicollet av and 17th st.

ASHMOUNT, MASS.—Lombard st, rubble stone and fr bldg for Ashmount Hall School Association; b, F M Severance; a, Edwin J Lewis, Jr., Boston.

OCALA, FLA.—Br Episcopal Church.

HEMPSTEAD, L. I.—Baptist Church 65x70 feet. Residences are being erected for John McLean, Edward Flannigan, William Doxey, Louis Cohen, Harry Akley, and George D Smith.

TERRYVILLE, L I.—Town hall bldg.

BAY SHORE, L I.—Cottage; o, Frank P Pike.

ROME, N Y.—Madison st, br addn and hospital; cost, \$4,000; o, N Y I for Deaf Mutes; a, Withers & Dixon, Albany; b, contract not let.

2 wrought iron bridges; cost, \$3,500; o, city of Rome; a, G C Schiller, Engineer; b, Canton Bridge Co.

MILWAUKEE.—Wm H Bradley, 212 Wisconsin st, will build a \$10,000 res at his summer resort about 3 miles from Oconomowoc.

10th, between Chestnut and Prairie, fr elevator; cost, \$10,000; o, Ph Best Brewing Company; b, Osca Knie.

3d, between Lee and Wright, br store; cost, \$10,000; o, A Strauss; b, H Schmitt & Co.

N w cor 14th av and Woodstock pl, br res; cost, \$15,000; o, S Wohrab.

Clinton st, br foundry; cost, \$8,000; o, Tiler & Stowell Co.

Cape, factory; cost, \$10,000; o, Schroeder Lumber Co.

Galena, br dwell; cost, \$9,000; o, J C Schroeder.

Grand av, br dwell; cost, \$8,000; o, Wm Steinmeyer.

Sixth, double dwell; cost, \$8,000; o, J Kraatz.

Cold Spring av, church; cost, \$7,500; o, Lutheran Trinity Church.

25th, dwell; cost, \$10,000; o, G A Parker.

Lake av, br laundry; cost, \$7,000; o, Industrial School.

Racine, br dwell; cost, \$7,000; o, Albert Wallber.

Menomonie, alt; cost, \$10,000; o, Mann Bros.

3d, br store; cost, \$18,000; o, Kahn Bros.

87 bldgs under \$7,000.

BOSTON.—44-50 Palmer, br dwells; cost, \$7,000 each; o and a, J G W Mason; b, J Nickerson.

Spice, near Cambridge, fr brass foundry; cost, \$9,000; o, Deste & Co; b, G T Burnham.

Waukegan, fr dwell; cost, \$7,500; o, Neil McNeil; a and b, McNeil Bros.

LITCHFIELD, ILL.—Br blk, 62½x124 feet, steam-heat; o, Thomas Rhodes.

CHATTANOOGA.—Montgomery st, br school house; cost, \$18,000; o, City; a, R H Hunt; not let.

CHARLEVOIX, MICH.—A Baptist church will be built here.

BIRMINGHAM, ALA.—A Union Depot will be erected here; also a new hotel.

(Continued on page 593.)

TOO LATE FOR CLASSIFICATION.

CAMDEN, N. J.—The Supervising Architect of the Treasury has rejected all bids on the Government Building here, and will receive new ones until the 28th inst.

PLAINFIELD, N. J., Common Council has contracted with the Plainfield Electric-Light Company to light the city entirely by incandescent lamps.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1887, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 16. }
NUMBER 22. } PUBLISHED EVERY SATURDAY.

NEW YORK, OCTOBER 29, 1887.

THE HEALTH OF MASSACHUSETTS.

FROM the forty-fifth registration report of the State of Massachusetts, for the year 1886, we learn that there were recorded during the year 50,788 births, 18,018 marriages, and 37,244 deaths. A fair estimate of the population is 1,976,264, giving a birth-rate of 25.69 and a death-rate of 18.85 per 1,000. This is a lower death-rate than that of any previous year since 1879.

Of the counties Nantucket has the highest death-rate—viz., 32.8—and Franklin the lowest—viz., 16.1; that is to say, the death-rate in Nantucket was a little more than double that of Franklin. But the total number of deaths in Nantucket was only 103 and in Franklin 608, and for such small numbers the probable error in ratios is so great that it is difficult to make reliable comparisons in this way. When we turn to the causes of death and find that in Nantucket 23 deaths, or 21 per cent. of all the deaths, were due to diphtheria and croup, 7 per cent. to shipwreck, and 11 per cent. to old age, it is evident that the high death-rate is in part accounted for.

These registration reports are among the best work which Massachusetts is doing. They are the best of the kind in this country, the data are fairly complete and accurate, and they are well tabulated. Very few at present appreciate their value and importance, but each succeeding year will increase this appreciation, and they form a substantial and enduring record of the most valuable possession of the State—viz., the life and health of its citizens.

Every library and every health officer in this country should take care to secure these annual volumes as they appear, and every State should endeavor to obtain for itself similar records.

EADS' LAST WORK.

THE extraordinary success achieved by the late Captain James B. Eads as a financier and a promoter of vast enterprises have led many to comparatively underrate his pre-eminent abilities as an engineer, considering it hardly possible that any one man could combine in himself such varied gifts in such a high degree, or if they gave him credit for being an engineer at all it was only as an engineer in a large and general way—one capable of conceiving great things, but having to depend for their successful achievement on the able assistants with whom he always surrounded himself, and this mistaken opinion has been strengthened by the generous way in which he always gave his assistants all the credit that was possibly due them.

To show his abundant ability not merely to originate gigantic schemes, such as but few men would have dared to undertake, even had they been able to conceive them, but also to skillfully and minutely plan all the varied details necessary for their practical accomplishment, we are pleased to be able to give a letter written about ten days before his death to an engineer of this city, and to reproduce some sketches from his hand on another page. In so doing we feel we shall also gratify the natural interest that all must feel in the last work of so great a man. Moreover, we cannot disguise the satisfaction, tinged with sadness though it be, that we feel in writing of one about whom we know that the best that can be said is not too much to say.

A SUGGESTION FOR THE BUILDING LAW.

BEFORE the echoes of the fall of that Harlem school-house have died away it may be well, as one of its causes was "dangerously rapid work," to suggest that the speed as well as the character of such work be regulated by law; in other words, that not more than so many feet be allowed to be added to the height of a wall each day.

It is useless, however, to improve the building law if it is not enforced. If the law provided that no wall should be more than ten feet high or less than ten feet thick, buildings would continue to fall down just the same under such methods of inspection as prevailed until recently in at least one district of this city.

THE EFFECT OF TEMPERATURE UPON STRUCTURAL IRON OR STEEL.

OUR readers will find in this issue some extracts from a very interesting paper on "The Effect of Temperature on Structural Iron and Steel," read by Mr. Joseph Ramsey, Sr., at the regular monthly meeting of the Engineers' Society of Western Pennsylvania held in Pittsburgh on the 18th inst. We regret that lack of space compelled us to omit from the paper several valuable tables giving in detail the results of Mr. Ramsey's experiments and tests.

WE quote elsewhere from the Washington *Star* its report of a decision by Chief Justice Bingham, in which the Commissioners of the District of Columbia were required to issue a permit to a plumber of that city who contested their right to enforce certain regulations promulgated by them. It will be seen that the court recognized the propriety of the regulations and the duty of Congress to confer the power on the commissioners to make and enforce them, but it was reluctantly compelled to issue a mandamus on the ground that the original act did not confer the necessary authority. There is no doubt that this decision will result in their securing the needed powers from the next session of Congress, so that their temporary defeat will have the effect of securing them the authority which it seems they have hitherto lacked.

THE New York *Sun* has some time since directed the attention of our capitalists to the profits likely to result from an undertaking which would provide the city of Mexico with a good system of drainage and sewerage, the first important work being the drainage of the valley of Mexico, so as to make it practicable to construct a sewerage system for the city. This is not a new project. A beginning even has been made, as we noticed last fall; but the work seems to be delayed, waiting for some contractor with strong financial backing to take it up and carry it through to completion. Probably the reason why American capital has not yet turned to this quarter is one lightly treated by the *Sun*—viz., the want of confidence in the stability of Mexican institutions and in the ability of the Government to discharge the obligations which this work will incur. But the Mexico of to-day is a very different Mexico from the turbulent country of the days following the French invasion. The country is quiet, and the Government is able to maintain peace and order, and

is said to be able to meet all its obligations regularly. Of the natural riches of the country and the advantage of this work to the city of Mexico there is no question. We are of the opinion that Mexico offers one of the most promising fields for American enterprise and capital.

HEALTH REPORTS OF GERMANY.

THE first and second parts of Volume II. of the Special Reports issued by the Imperial Board of Health of Germany have recently been published in the form of a quarto volume of 222 pages, with maps and illustrations.

It contains a paper on micro-organisms in artificial seltzer-waters, by Dr. Hochstetter; a report on the cholera outbreak in Sosenheim and Finthen in the fall of 1886; a report on the results of vaccinations in Germany in the year 1883; a paper on tests of waters at Rudolstadt, by Dr. Wolffhügel; a report on lead and zinc in the arts and in daily life as sources of danger

more advisable to build a new bridge or tunnel at that point, so, at a recent meeting, they decided to invite General John Newton, Mr. E. B. Van Winkle, Mr. G. W. McNulty, and Thomas C. Clarke to examine the locality and advise as to the relative advantages of a fixed bridge, a draw-bridge, or a tunnel, with estimates of cost. A viaduct from Washington Heights to McComb's Dam Bridge is also in contemplation, and plans for a structure to cost about \$800,000 are nearly completed.

At the Hygienic Congress at Vienna, Herr Pettenkofer, lecturing on hygienic education and the necessity of spreading hygienic principles among all classes of society, largely quoted English authorities, and in alluding to the English proverb, "Cleanliness is next to Godliness," remarked that the statistics of the mortality of London show how hygienic piety has been rewarded by Heaven. Here is comfort and encouragement indeed for apostles of hygiene, toiling in the narrow way that leadeth unto life. —*London Builder.*

perfect. He quotes an instance where the electricity in passing from link to link encountered a resistance sufficient to enable it to partly fuse the chain. A lightning-rod without sufficient earth connection is worse than useless, as it invites a danger which it cannot avert. It is the lower end of a lightning-rod that is emphatically its "business end."

AFTER a series of experiments to decide the question of the superiority of the gelatine as compared with the water cartridge made at the North Staffordshire Mining Institute, it has been decided at the Shelton collieries to use the gelatine cartridge.

WE are promised from Paris a new excitement in the shape of a steam balloon. The form of this contrivance is to be that of a fish, with a length of about 200 feet, suspended from which will be the car carrying a steam-engine weighing 1 ton 13 cwt. connected to a screw. The I. H. P. is 70, and the inventor anticipates a speed of about fourteen miles an hour.

A GARDENER'S COTTAGE.—M'KIM, MEAD & WHITE, ARCHITECTS.

to health, by Dr. Wolffhügel; and a report on the mortality of infants in Germany during the years 1875-77, by Dr. Würzburg. All of these are careful, thorough pieces of work, the force and value of which can only be appreciated by practical men.

IN view of the Kouts railroad disaster, in which the car-stove caused the death of some dozen or more people, it would seem that the law of this State will require amendment at the next session of the Legislature, since under this law railroad companies are allowed to keep a fire in a car when standing still. This train happened to be standing still with a broken engine and another engine ran into it; but the car-stove did the damage just the same.

THE Board of Estimate and Apportionment of this city has decided that it would be a waste of money to spend \$60,000 in repairing McComb's Dam Bridge and the Park Commissioners are of the same opinion, believing it to be

A COMPRESSED-AIR locomotive for underground work for mines, etc., is exhibited at the Newcastle Exhibition, and it is stated that several such engines are in use in the Durham Mines. The locomotive runs on a 33¼-inch gauge, and its total weight is about two tons. The pressure of the air is about 400 pounds to the square inch. On a medium road the maximum load of the engine is twelve tons, and with five tons the air charge will last about a mile.

LIGHTNING-CONDUCTORS.

APROPOS of the recent prevalence of thunder storms, Professor Tyndall has been drawing attention to the best methods of connecting lightning-conductors with the earth. He points out that conductors are very frequently laid in the earth without any terminal plate whatever, that the abolition of resistance is absolutely necessary in connecting lightning-conductors with the earth, and that this is best done by closely imbedding in the earth a plate of good conducting material and of large area. He objects to chain cable for the purpose of prolonging a conductor, on the ground that the contact of link with link is never

AMERICAN INSTITUTE OF ARCHITECTS.

WE devote considerable space in this issue to a report of the twenty-first annual convention of the American Institute of Architects held at Chicago. As will be seen, this session was of more than usual interest. A number of good papers were read, abstracts of which we hope to give our readers in future issues. All those attending felt their appreciation of the liberal hospitality extended by the Illinois Society of Architects and the Chicago Chapter. The members were entertained three days at lunch, carriages furnished for drives about the city each afternoon; indeed, everything was done to make their stay pleasant and profitable in that interesting and remarkable city. Mr. Walter and Mr. Bloor declined a re-election as President and Secretary respectively. Mr. Richard M. Hunt was elected President, and Mr. William A. Potter Secretary.

ON THE MANUFACTURE OF SALT NEAR MIDDLESBROUGH.

FROM a paper by Sir Lowthian Bell, read before the Institution of Civil Engineers, we abstract the following interesting data. This salt bed, near the mouth of the Tees, was discovered through an attempt made by Messrs. Bolckow & Vaughan to obtain pure water for their engines. The deposit, so far as developed, covers about $7\frac{3}{4}$ square miles, is from 1,090 to 1,674 feet below the surface, and varies in thickness from 65 to 117 feet, and the various strata contain from 98 to 37 per cent. of salt. The author estimates the total quantity at 100,000,000 tons, one acre of pure salt one inch thick weighing about 100 tons.

The estimates of the cost of sinking a shaft through the wet strata to the salt varied from £100,000 to £200,000, and it was determined to introduce water and extract the salt by pumping the resulting brine. Accordingly a tube, say 12 inches in diameter, with a series of holes near the bottom and another series of holes near the top of the salt, was sunk a short distance into the limestone floor of the mine so as to anchor it. Another pipe having an annular space of from 2 to 4 inches, with a series of holes near its bottom, is sunk inside of the larger pipe, with its lower end also anchored in the limestone. The water is introduced through the annulus and is pumped through the minor tube, which has a clack-valve some distance below the surface.

The water passing through the holes in the water-pipe dissolves the salt, gradually forming a cavity in the shape of an inverted cone, as the pure water, which is lighter than that nearer saturation, takes up the larger percentage of salt.

The rate at which the salt is dissolved depends, of course, on the extent of surface exposed to the action of the water. This at first is very slow, and for some months the quantity of salt furnished by a well is inconsiderable and the brine is weak.

A fully-saturated brine contains $26\frac{1}{2}$ per cent. by weight of salt and has a specific gravity of 1.204, hence a column of pure water 100 feet high will balance about eighty-three feet of saturated brine. The clack-valve should be some distance below this point.

A pump working eight hours per day is considered to do well if it raises 250 tons of salt per week. Seventeen wells now in use about Middlesbrough are thought to raise from 2,700 to 3,000 tons per week, or less than 180 tons each.

The plan adopted, though economical, is objectionable because the large extent of unsupported roof left by this mode of operation invites falls, some of which have already broken the pipes, and the impure strata being attacked from the top, the earthy matters fall on the salt and prevent the water reaching all of it.

The brine is pumped into reservoirs and allowed to settle, and then evaporated in iron pans 60x20x2 feet, by the use of refuse coal or waste heat from the smelting furnaces.

About 2,250,000 tons of salt are made in England annually, one-eighth of which is brought to the banks of Tyne, and converted into soda by the Le Blanc or the Solvay process.

By the first method the salt is heated with sulphuric acid, producing "salt cake," and setting free chlorine, from which bleaching powder is made.

The salt cake is reduced to black ash by using 100 parts with 140 parts of broken limestone, and 40 to 70 parts of coal, and the resulting carbonate of soda is obtained by lixiviation. The waste in this process is sulphur; the sale of the bleaching powder, a by-product, adds to the profits of the operation, and sometimes is of greater value than the soda.

In the Solvay process ammonia and carbonic acid are forced through a pure lime, thus saving the cost of evaporation, giving bicarbonate of soda and chloride of ammonium, sal ammoniac. The bicarbonate of soda is roasted in a reverberatory furnace, where the adhering water, one equivalent of carbonic acid, is driven off, leaving a mon carbonate. Most of the ammonia is recovered by treating the chloride of ammonium with milk of lime; the chloride of calcium formed being run to waste.

AMERICAN INSTITUTE OF ARCHITECTS—TWENTY-FIRST ANNUAL CONVENTION.

CHICAGO, for the second time in its history, welcomed the American Institute of Architects, on the occasion of the twenty-first annual convention of the institute, October 19-21, and the attendance was the largest in years. The sessions took place in the rooms of the Literary Club, in the Art Institute, corner of Michigan Boulevard and Van Buren Street, while every noon, as the guests of the Chicago Chapter of the Institute and of the Illinois State Association of Architects, the assembly lunched at the neighboring Union League Club-house.

The first day, Wednesday, opened at 11 A. M. with an address, in the absence of President Thomas U. Walter, LL.D., detained in Philadelphia by severe illness, from First Vice-President Edward H. Kendall.

VICE-PRESIDENT KENDALL'S OPENING ADDRESS.
Fellow Members of the American Institute of Architects:
Having known for only two or three weeks that, owing to serious illness, our esteemed President, Mr. Walter, could not be with us to-day, I can do little more than call you to order, and formally endeavor to perform the duties of Chairman.

I shall ask you, however, to undertake the business of this our Twenty-first Annual Convention with that especial dignity of bearing and soberness of purpose which would seem to be called for upon the attainment of our corporate majority, and will remind you that we are called together in this great and prosperous city for the purpose of exchanging our annual greetings, of renewing our allegiance one to another, of giving evidence that we are competent to do the work required of us, of investigating the current developments in the science and art of our profession, and of increasing our usefulness to ourselves and to our clients in all possible ways.

We shall listen to papers from representative men upon subjects of especial interest, and reports of important committees must be heard and acted upon.

One of the greatest difficulties encountered by your Board of Trustees, now that our field is so much enlarged, is the frequent meagreness of information concerning candidates for membership, and, in order to reduce this difficulty to a minimum, must we not soon devise a better method than the present one of determining whether or not those who wish to join us are qualified by education, by business habits, and by personal characteristics to so influence public opinion that we may command the respect and confidence of the several communities in which we work?

Whether the present method can be made sufficient by a keener sense of responsibility on the part of those who know the applicants for fellowship or associateship, or whether we should create an office, in the nature of a traveling secretaryship, the duties of which would be to come in personal contact with all our members and would-be members, and, by intercourse and correspondence, to make the institute more surely a common ground where the best instincts and interests of our profession should centre, is a subject which we ought soon carefully to consider.

We must all feel gratified by the growing interest taken in our institute, which is clearly shown by the unusually large number of applications for membership and of requests for information as to the organization of additional chapters during the past year, and you will all bear me out when I say that we are especially glad to have admitted so many who are also members of the Western Association of Architects.

It is our wish to have the active co-operation of all the best men in the profession, and the being a member of other associations or societies, instead of being a bar against, is in fact the very best reason for joining the institute, as it would then get the benefit of doubly-organized work, and the general welfare would be correspondingly advanced.

Then, again, we wish to see and personally know all those who are doing good work in this great country, and the day will soon come when these annual meetings will be eagerly looked forward to and be largely attended, and when they will be considered not so much from the standpoint of duty as from that of pleasure and privilege; then also will the American Institute of Architects accomplish its highest degree of usefulness when it becomes the chief vehicle of professional pleasures as well as of professional duties, and when, to the formal requirements of routine and committee, is generously added the fraternal leaven of impulse and comity.

Secretary A. J. Bloor read the report of the Board of Trustees. Nine meetings had been held since December 9. Twelve fellows and fourteen associates had been elected and one died. A new chapter was organized this year in Washington, where there was much architecture worthy of the national capital, the wedge-shaped sites affording such fine opportunities for pleasing display. A chapter had just been formed in Indianapolis in place of the Indiana Chapter, and correspondence was taking place with various parts of the country looking to the organization of other chapters. The Western Association of Architects had done well in memorializing Congress as it did; an harmonious request representing all architectural associations throughout the country must receive attention.

The Treasurer's report showed \$1,447.39 in the bank at different times during the year, of which \$1,210 came from dues, and the disbursements were \$1,288.36, leaving a present balance of \$159.13, with assets over liabilities about \$1,100. The nucleus (\$176.75) for building in New York City a permanent home for the Institute still remained a nucleus. [Laughter.]

Next, the Standing Committee presented a report, the first division being on education and written by Professor Ricker, of the University of Illinois at Champaign. The School of Architecture there had two courses—a building course, composed of nine studies in a single year, and meant for builders and mechanics desiring instruction in the rudiments. The second, or architectural course, was for young men preparing for the profession. No suitable text-books existing, lectures were resorted to. The elements of sanitary construction were taught, comprising the general principles of plumbing and drainage, supplemented by the use of engineering instruments. Original work from students was not required too soon. The history of architecture was very simple; but here again lectures were demanded, satisfactory text-books not existing. Students made sketch designs and architectural perspective was taught. On heating and ventilating the same lack of text-books was seen. No scientific topic existed on which the general public presumed it knew so much and really knew so little. The finally adopted plan of instruction on all these various subjects was to write out lectures with the typewriter, costing students little more than ordinary text-books. The present demand for draughtsmen throughout the West caused some disadvantage. It was difficult to get students to take the entire course, a considerable number of young men wanting to jump over the fences and make brick without straw. Some architectural schools were partly responsible for this, teaching but little mechanics, much less than that of the civil engineer, and naturally when it came to practical life and the survival of the fittest, students who had thus shammed went to the wall. The Champaign school gave the most thorough instruction possible and had the most complete apparatus obtainable. A State system of examination of architects was only a partial system; the foundation needed was a better education of the profession. Real improvement would come only in that way, the direct tests of annual and other examinations eliminating the ignoramus and the shyster.

Regarding "Publications," the Standing Committee reported that 750 copies of last year's convention journal had been issued by the secretary.

Then came reports from the various chapters of the institute, Baltimore leading off. During the past year Secretary Wilson reported that the chapter had regular meetings, but owing to the small membership they were not very well attended. The membership and general situation were in *statu quo*. The movement was still in progress for the passage of a satisfactory building law by the State.

Boston Chapter, as Secretary Edmund M. Wheelright reported, held monthly dinners, well attended, and at the several meetings attention was held by some special feature like the address of C. H. Blackall on his two years' travels, illustrated by sketches made by him; the drawings of the Algonquin Club, and essays by George Snell and others. Two prizes, aggregating \$100, were given the Massachusetts Institute of Technology, one for the best work in design, and the other for the best general work during the past year. Also, \$500 was given the Archaeological Institute of America toward publishing the report of the Assos Expedition. No fellows had joined during the year.

Chicago Chapter had increased in numbers to 27, and December 9 had elected L. D. Cleveland, President; W. L. B. Jenney, Vice-President; M. L. Beers, Treasurer; and Alfred F. Pashley, Secretary. A committee on Arrangements was appointed to act with the Western Association of Architects in welcoming the American Institute.

Cincinnati Chapter favored the union of the Western Association and the American Institute and of the local chapters, believing better results would follow. The Chamber of Commerce Building, the last designed by the late H. H. Richardson, and the new City Hall were buildings of the first class now in process of erection in the American Athens.

Indianapolis Chapter reported a situation satisfactory in all respects, with monthly meetings attended by three-fourths of the large membership and marked by very friendly and fraternal feeling, in place of the coolness and asperity too common in the resident profession, and the chapter now comprised every worthy architect in the city. The activity in building had been great, natural gas attracting large capital and construction enterprises. The Indiana State House, the City Hall and market building, and the coming monument (costing \$225,000) to the Indiana State Soldiers and Sailors, were examples.

New York Chapter, as usual, had done the greater part of its work through committees. The chairman of the committee on examining the New York building law, perfecting the same and presenting it at Albany for enactment, was elected chairman in a joint movement with the municipality, and the new building law is received with much interest. Modest mention was made of services by Messrs. Avery and Bloor. The chapter had passed memorial resolutions on H. H. Richardson, whose productions had not been surpassed by those of any other American architect, and whose career was an example to all aspirants, no matter how gifted in mind, of the value of careful training. At one meeting of the chapter H. O. Avery read a paper on the "Paris School of Fine Arts," since published in Scribner's. The Willard donation of between \$70,000 and \$80,000 to the Metropolitan Museum of Art would yield immediate practical benefits.

Philadelphia Chapter chronicled the great growth of local architecture the past year, in a large number of expensive office buildings, churches, residences, creating more demand on the architect's skill and services than perhaps ever before. In the erection of small dwellings

Philadelphia was still the "city of homes," both town and suburbs being covered with small houses. Chapter meetings were held with regularity and reasonable attendance.

Rhode Island Chapter, after supper at the monthly meetings, held divers discussions, competitive plans being the subject lately of a more formal debate. Secretary Edward G. Nickerson signed the chapter report.

San Francisco and St. Louis Chapters vouchsafed no reports.

Washington Chapter, Secretary Glenn Brown wrote, organized last June, and listened to a lecture, the first of a series, October 9.

The Secretary for Foreign Correspondence, Mr. Jenney, of Chicago, announced that he had but a meagre report. Nothing had occurred in twelve months demanding his good offices, he not even being called on to give a send-off to lucky fellows starting on their European travels. So he would have some younger, more energetic member as a successor. The first year he did very little, acknowledged the receipt of a New Year's card; the second year he did some better, and he was elected to a third term; but really he hadn't earned his salt.

As a Nominating Committee for the election of officers, Chairman Kendall named E. T. Nickerson, of Providence; Henry Lord Gay, of Chicago, and Mr. Smith, of Nashville; and on suggestion of Mr. Frederick, of Baltimore, two more were added—Mr. W. R. Briggs, on Mr. Frederick's motion, and Professor Ricker, on Secretary Bloor's motion.

Reports of special committees being in order, one was presented on the bill to provide improved methods in the architectural service of the Federal Government, in conference with Special Committee of the Western Association of Architects. The report stated that the bill would have to be introduced again at the next session of Congress and submitted a letter to that effect from Congressman A. S. Hewitt, who wrote that some member of the Committee on Buildings and Grounds who wanted to make a record must be procured to give his entire time to the matter. The report closed by recommending the continuance of the committee to bring the subject before Congress at its next session. So ordered.

On architects' protective associations, T. M. Clark, of Boston, reported that any action would necessitate exhaustive study of the laws of the several States and also special legislation.

On providing a permanent home for the institute, the committee reported that any such building should be fire-proof, in the business part of New York City, and complete in aesthetics and construction. A joint stock company should erect it and could realize five per cent. net, and have the upper floors set off for the institute. The report was "conditionally accepted, pending Mr. Bell's signature."

On a building contract for use throughout the United States, in conference with special committee of National Associations of Builders of U. S. A., the committee recommended the appointment of a committee of three to confer with the Western Association of Architects and the National Association of Builders and draft a contract properly protecting the interest of owner and contractor and submit the same to the next annual convention. So ordered.

The Chair named the following committees to consider the reports presented to the convention: On Trustees' Report, Messrs. Bell, Scofield, and Adler; on Auditing Treasurer's Report, Messrs. Burnham, Crapsey, and Drery; on other reports, Messrs. Cutler, McLoughlin, and Root. Greetings were read from the Alabama Association of Architects by W. S. Smith, President, and suitably acknowledged.

President Walter's condition was reported as very unfavorable.

The North-Western Terra-Cotta Company invited the convention to visit their works. Accepted, and Messrs. Jenney and Gay were named a Committee of Arrangements.

The exhibition of illustrations, it was announced, would not be ready for the evening, and instead the convention was invited to attend the Inter-State Exposition and inspect its art gallery and diversified clay-working machinery. After reference to Messrs. Jenney and Adler the invitation was accepted.

Thereupon an interesting discussion sprang up and lasted till the end of the day's session. Architect Adler, of Chicago, introduced it, asking how many members there were in the Institute.

"About 225 members in all," replied Secretary Bloor. "Yes, the old limitation of seventy fellows was abrogated some time ago."

Mr. Adler—What objection is there to making all members fellows at once?

Secretary—It would be simply going back on the old record.

Mr. Adler—Any architect who is not a villain, horse-thief, or boodler may and will become a fellow if he wishes, may he not? That is, it only requires that two fellows recommend him for advancement, that he be willing to pay additional dues, and that he shall not have made himself so obnoxious to his fellow members of the institute as to cause a number of them to write over their own signatures and protest against his admission.

Secretary—The trustees exercise their own discretion in the matter. We very frequently object to candidates. We have objected to a number during this last session. The by-law shows you that.

Mr. Adler—I have not read the by-laws. I have simply noted the practice.

Secretary—All I can tell you officially is that after nomination by two fellows a candidate must be elected by the

Board of Directors. [Then followed the reading of by-laws providing for communication with all fellows and associates regarding every new applicant.]

Mr. Adler—That is explicit enough, I grant. But is it not the case that where an associate is recommended for advancement to fellowship and these letters of inquiry are sent out, almost invariably no opposition is made, no adverse answers are received; that except with reference to people who are valoriously unprofessional in the management of their business, notoriously incompetent to discharge their ordinary duties, architects dislike very much to place themselves on record in remarks derogatory to their fellow practitioners; and is not the result really this, that as far as the information you obtain from members of the institute, or from chapters at least, these inquiries might as well not be sent out at all? Is it not a fact that you receive no information that would lead you to reject?

Secretary—A great many letters reach the Board of Directors which are very severe on the applicants for admission. They are considered and frequently affect the course of the matter. Vice-President Kendall will remember it.

Vice-President—Yes; we frequently have occasion to act on such representations. I know that some are put out—vexed—that they are not advanced at once. But the object has been to have the two grades. I was an associate for a great many years and I always looked on the position of fellow as placed higher, and I felt a certain diffidence about applying for the position, but was prevailed on later and am very glad to be one.

Secretary—We have been much more indulgent lately in case of candidates from Chicago. [Laughter.] We thought it proper to receive candidates from Chicago—from the Western Association of Architects. We were particularly indulgent [smiles], although the secretary had from Chicago one or two adverse letters.

Mr. Briggs—Is there any special qualification required in a fellow that is not required in an associate?

Secretary—Very often we don't know the candidate for associate by reputation; generally we do know the candidate for fellow.

Mr. Briggs—In case of a very prominent man, a man we all know, applying to this institute and wishing to become a fellow, how long must he be an associate, if at all, before he can become a fellow?

Vice-President—It is left to the discretion of the directors. There is no restriction. He might be elected fellow at once, or placed under probation, in some instances. But in case of younger members and in all ordinary cases we consider it well that they should become associates first.

Mr. Briggs—But it is possible to elect to fellowship outright?

Vice-President—It is.

Mr. Adler—It is my belief that we should either have absolute equality in membership throughout our organization, or if we have two grades of membership, that particular pains should be taken to guard the matter of admission to the higher grade, and perhaps also, as a means of securing that end, that a limitation as to numbers be set to the membership of this higher degree. And to test the sense of this convention upon these two points, I will offer first a resolution to the effect that from and after this date, all who are now associates of this institute be advanced to the fellowship, and that hereafter all members of the institute admitted shall at once become fellows.

Secretary—That resolution is inoperative, not having been submitted thirty days in advance of this convention.

Mr. Jenney wanted a reference to a committee of three to report to the next convention.

So voted.

Mr. Briggs—This is simply to report, I understand it, whether to admit the rank of associate or to make a most decided and strong distinction between it and the rank of fellow.

On a further motion by Mr. Jenney a modification was carried that the committee on reference be the duly elected trustees for the coming year.

Mr. D. Adler, fellow, then read a paper on "Theatres."*

The second day's session opened at 11:30 Thursday. Vice-President Kendall in the chair and a large attendance. A letter, regretting his absence, was read from Mr. Le Brun, of New York, of the Board of Trustees.

An amendment to the by-laws was carried prohibiting the election of professional architects to the position of honorary members.

Another amendment offered was to limit any man's service as President to two years consecutively, and conferring on an ex-President of two years' service and over seventy years of age exemption from payment of dues and the position of a Vice-President.

The Committee on Nomination of Officers presented a list that at once caused discussion, the nominee for President being Edward H. Kendall, of New York.

Mr. Kendall stated he regretted to find his name on the list. For the moment I should think Dr. Walter should remain your President, and after him there is only one man in the country who should be President of the American Institute of Architects, so far as men in New York are concerned. That man has a reputation not only in America, but it goes far beyond it, to England, France, and, in fact, all the adjacent European countries—Mr. Richard M. Hunt, of New York. I must very respectfully decline your nomination.

Secretary Bloor, referring to a private letter handed him by a Mr. Cutler, of Rochester, said that it was in favor of

the present incumbent being replaced by another. Also another letter was received from ex-Secretary George C. Mason, urging that no intimation of slight be put upon "the present father of American architects"—Dr. Walter.

Vice-President Kendall—I suggest that the nominations be referred back to the committee.

Mr. Cutler—I understood that Dr. Walter definitely declined a year ago to be a candidate for re-election at this convention.

Another fellow—I heard him distinctly say last year that he would take it only one year more. He is doubtless too ill now to give the matter any thought.

Mr. W. R. Briggs, of the Nominating Committee—The Committee on Nomination had this in view that Dr. Walter was not a candidate. They did not for a moment think to hurt his feelings, but understood that he declined.

The Secretary read Dr. Walter's words of acceptance a year ago, the closing sentence being, "If I live another year, I will get you to allow me to take a rest."

Mr. Cutler moved that a committee of three transmit to Dr. Walter hearty resolutions expressive of the valuable services rendered by him during the long term of his presidency and of the regard that all felt for him, the occasion of the testimonial being the fact he had absolutely declined re-election to the office he had held so long.

Mr. John Moser—And embodying the fact that we have given him all the honors that he would accept.

Carried unanimously, and the Chair said he would name the committee later.

A letter from Mr. Avery was read by Mr. Bloor positively declining to be made secretary. The subsequent discussion developed the fact that Mr. Avery is ineligible being only an associate member.

Mr. Adler—Has Mr. Hunt exhibited a willingness to accept the position? As Mr. Hunt has not seen fit to attend the convention it might indicate that he would not accept.

Vice-President Kendall—Up to within a few days Mr. Hunt, I understood, had proposed to come, but he was ordered to Washington by the Government in connection with the new naval observatory.

The Secretary—That is what he says in a letter to me.

Mr. Willett—The fact that Mr. Hunt is not here and has not sought the office is rather a recommendation.

The Secretary—I agree with Mr. Willett that the non-attendance of Mr. Hunt may be taken as an indication not that he does not desire the office, but that he felt it a matter of delicacy not to be here when he thought his services might be asked.

Vice-President—I know Mr. Hunt to be as unassuming as he is competent.

Mr. Bloor (replying to another question by Mr. Adler)—Yes; I have every reason to believe he will accept it, and take it as an honor.

Then the nominations were referred back to the committee to be purged of several names of associates, made by the constitution ineligible to office.

Mr. Bell, of the committee on the trustees' report, recommended that its recommendations be taken up *seriatim*. Accepted. Similar action was taken on the Audit Committee's report. Next came the report of the special committee on reports, etc. It favored printed forms for reports from chapters, not limiting reports from the chapter secretaries, however; it favored a continuance of the committee on permanent home; that the report of the committee on uniform contracts be accepted; that all protective work deemed desirable in the interests of the institute be undertaken by the institute within the limit of the present organization; that the committee's report on improvement of Federal architecture be accepted and the committee continued with the addition of M. E. Bell, late Supervising Architect, and one other architect representing the district west of New York.

Mr. Bell, late Supervising Architect, followed with a paper on "The National Building Question."

Thanks having been voted Mr. Bell, and his paper accepted, Mr. W. W. Boyington next entertained the convention, his subject being "Differences between the Methods of Architectural Practice prevalent now and fifty years ago." Half a century ago was an earlier period, he said, than his practical experience as an architect covered. It was, however, in the earlier years of his studies in architecture. There were no schools of technology nor polytechnic institutes then, and there were but very few professors and teachers of architecture. He commenced under Professor Stone, of New York, studying classic architecture. Matters then considered essential were wholly disregarded now. Chicago to-day had more architects than the whole country then, and, excepting electricity, architecture had made greater strides than any other of the arts and sciences, and to-day the American profession could vie with that in any country. Fifty years ago this country knew no style in architecture except classic and gothic, and but very few pure examples of either had been produced, the majority of buildings of the period being plain and built by master builders who usually made their plans on the trestle board, designating with white, red, and blue chalk the timber, slate, and brick entering into the construction. His father was a master builder and used to make his own plans largely in the way indicated. Architectural publications had increased in proportion to the profession, now numbering upward of 3,000 practitioners. Fifty years ago architects were largely supported by contractors. Now owners had found it necessary to deal directly with architects, yet still there were many impecunious persons who did not do so—Philadelphia especially having comparatively few architects. Thirty-four years ago, coming to Chicago, he found the architects in practice

* Abstracts of papers read will be printed in subsequent numbers.

were recently master builders or contractors, and indeed Chicago and the West could hardly be said to require the services of architects, the buildings were so simple. The first architect in Chicago was prevailed on to quit building and confine himself to making plans on being guaranteed \$2 per day, even should the sale of plans bring less. One day he took in \$5 for a plan and was in high feather over the circumstance. The speaker was introduced in the infant city as a young architect from Massachusetts, and was often asked what was the business of an architect. He immediately instituted the practice of charging a percentage on the cost of buildings, the amount to be always collected from the owners. This departure was rather uphill work, but it succeeded, and from that small beginning Chicago could to-day boast of as fine and capable a corps of architects as any city in the Union, and the architect who first commenced the practice of the profession in Chicago was still living and in business, while the speaker's own services had radiated out from gulf to lake and Atlantic to Pacific, and his lot it was to construct the first cab used over a locomotive engine in this or any other country.

Charles H. Ham then read a paper on "Manual Training as Applied to the Building Arts." It was always, he said, the hand that came to the rescue of imagination and speech. From the rude hut to the splendid mansion was a long progression, and it was not achieved by mind alone. It was only in mythology that thought created; in real life things of beauty sprang only from thought and hand combined. The steam-engine of Watt existed in the mind of Hero of Alexandria, but to develop Hero's thought required two thousand years of experiment. It was the hand that quarried each stone, fashioned every timber, made the mortar, drove every nail. The work of the hand was not confined to the grosser departments of art. It traced on paper the builder's initial thought, a thought too subtle and insubstantial for expression in words. It was the mind's faithful coworker, rounding the dome, pointing the spire, and overlaying all with the grandeur whose design was not more largely beautiful than finely wrought. There was more imagination, sentiment, humanity in a locomotive than in the statue of Praxiteles, the painting of Raphael, or the work of Shakespeare. The coeducation of the mind and the hand was a duty to society and the State, and was plainly the road to the solution of the labor problem, as it would dignify labor and result in a fair distribution of the fruits of labor among those contributing to their production. "Thou shalt not build and another inhabit; thou shalt not plant and another eat."

Secretary Bloor—I move that be accepted, with thanks for the very fine and able paper. Carried.

Then the Nominating Committee reported a second time, as follows: President, R. M. Hunt, New York; Secretary, William A. Potter, New York; Treasurer, O. P. Hatfield, New York; Board of Trustees, N. Le Brun, New York; L. T. Scofield, Cleveland; H. M. Congdon, New York; John W. Root, Chicago; Committee on Education, Professor N. Clifford Ricker, Urbana, Ill.; Alfred Stone, Providence; Professor W. R. Ware, New York; J. W. McLaughlin, Cincinnati; Henry Van Brunt, Boston; Committee on Publication, Charles Crapsey, Cincinnati; T. M. Clark, Boston; S. S. Beman, Chicago; George C. Mason, Jr., Newport; Secretary for Foreign correspondence, Arthur Rotch, Boston.

Mr. Adler—If these nominations are now satisfactory to our present Board I move that the nominations be accepted.

Mr. Bell—Will Mr. Potter accept the Secretaryship?

Mr. Bloor—I have promised to beg him to.

Mr. Kendall—And the constitution provides for a vacancy that the present officers shall hold over.

Then by one ballot all the nominees to office were elected.

Henry Lord Gay presented a very eulogistic memorandum on the retiring Secretary, A. J. Bloor, proposing not only thanks, but a pecuniary compensation—conformably with the circular sent out—for his very laborious and acceptable services, and that a salary be given thereafter to the Secretary.

Mr. Bloor, expressing appreciation of the friendly words, disclaimed all official knowledge of the circular referred to.

Mr. Briggs proposed an amendment to the by-laws, to be acted on in due course, doing away with the clause setting forth that associates are not eligible to hold office.

Adjourned for lunch at Krosley's, and subsequently a carriage ride to North Side points of architectural interest, including the North-Western Terra-Cotta Works.

In the evening the institute assembled at the Permanent Exhibit of Building Materials and Appliances. The attractions of the resort were set off by a well-mounted exhibition of illustrations of work executed within the last ten years by practitioners invited by the Western Association of Architects. Very few but Western articles were represented, but the exhibit proved to be very interesting for an hour's inspection.

Subsequent to this, a short evening session was held in the hall of the Permanent Exhibit, and an illustrated paper was read by John Moser, fellow, on "Federal Buildings for Judiciary, Customs and Postal Service." It was very minute and analytical as to the interior features. In external style there should be nothing antiquated, he said, but everything pitched on the modern key. It should have a red stripe down the parts, as it were, to give an official smack to it all. The dress should be no misfit, but a dignified, tailor-made garment. The arms of our Gov-

ernment belonged here as much as on a silver dollar. It should be massive, powerful, leonine. It should show the most careful refinement and the simplest as well as the most ornate forms, and the perfection of its workmanship should challenge attention everywhere. It should look its best in the present, not requiring partial disintegration to make it artistically interesting. Domes and fancy pinnacles were to be excluded, it being a business building and not for parade, and perhaps the square-top roof was best. The Classic style was too sacrificial, the Romanesque too warlike, the Gothic too sacerdotal and spiritual. The ideal Government building, he thought, should have the grace of the French school, the refinement of the Florentine, the strength of the English, and the system of the German.

Adjourned.

The architects, members of the Institute, attending one or more sessions of the convention, were as follows: Edward H. Kendall, New York City; O. P. Hatfield, New York; A. J. Bloor, New York; N. Clifford Ricker, Champaign, Ill.; D. H. Burnham, Chicago; Warren R. Briggs, Bridgeport, Conn.; Edward J. Nickerson, Providence; Henry W. Hill, Chicago; Alfred F. Pashley, Chicago; John J. Deery, Philadelphia; S. S. Beman, Chicago; Fred H. Gough, Utica; William S. Wicke, Buffalo, N. Y.; S. A. Treat, Chicago; Normand S. Patton, Chicago; George A. Frederick, Baltimore; Otis Dockstader, Elmira, N. Y.; George W. Rapp, Cincinnati; James Cutler, Rochester, N. Y.; J. Mason Maury, Louisville, Ky.; C. A. Wallingford, St. Paul, Minn.; Charles Crapsey, Cincinnati; John W. Root, Chicago; L. D. Cleaveland, Chicago; C. M. Bartberger, Pittsburg, Pa.; Eugene H. Taylor, Cedar Rapids, Iowa; Henry Lord Gay, Chicago; Adolph Cluss, Washington; E. L. Walter, Scranton, Pa.; Louis H. Sullivan, Chicago; J. F. Alexander, Lafayette, Ind.; C. H. Brodie, A. R. I. B. A., London, Eng.; C. A. Curtin, Louisville; John Ord, Philadelphia; M. E. Bell, Chicago; W. Bledwyn Powell, Philadelphia; William Aiken, Cincinnati; William C. Smith, Nashville, Tenn.; C. J. Clarke, Louisville, Ky.; William W. Clay, Chicago; Melvin P. Hapgood, Hartford, Conn.; S. V. Shipman, Chicago; William Holabird, Chicago; J. L. Silsbee, Chicago; J. J. Flanders, Chicago; W. L. B. Jenney, Chicago; Albert W. Gibson, Albany, N. Y.; W. A. Otis, Chicago; S. R. Burns, Dayton, O.; D. Adler, Chicago; John Addison, Chicago; August Fiedler, Chicago; John Moser, Washington, D. C.; Levi T. Scofield, Cleveland, O.; A. Smith, Chicago; James W. McLaughlin, Cincinnati; W. R. Brown, Cincinnati; P. B. Wight, Corresponding Member, Chicago; F. L. Charnley, Chicago; W. G. Preston, Boston; James R. Willett, Chicago.

The convention was called to order by a mallet made from the keel of the "Kearsarge."

The Committee on Arrangements consisted of W. L. B. Jenny, E. T. Littell, Henry Lord Gay, and A. J. Bloor. The Chairman of the Reception Committee was S. H. Treat.

The third day's session began with a paper by D. H. Burnham, fellow, on "Suggestions towards the best and speediest methods for harmonizing and utilizing all the architectural societies in the United States, so as to secure the most good for architecture, for the public, and for the profession in America; due regard being had, as concerns means, alike to individual energy and enthusiasm, and to associative experience; and, as concerns ends, alike to local sentiment and to national reputation."

This paper from the start commanded exceptional attention, as it was known in advance to advocate the death of all existing architectural societies and their resurrection into one united whole.

[This paper will be printed in a subsequent issue.]

Mr. Burnham on closing his paper offered the following resolution: "That a committee of five members be appointed, of which the chairman of this convention shall be a member ex-officio, the other four members to be selected by him, to act jointly with one of similar number to be appointed by the Western Association of Architects at their next general meeting, to report as to the best and speediest method of consolidating all the architectural societies of America into one organization, the report to be full regarding form of constitution for local societies and also form of constitution, permanent place of meeting, and proper quarters for the national or representative body. That the Western Association of Architects be and they are hereby cordially invited to unite with us in this work and to appoint a committee as above."

Mr. Bloor—I second the motion. I consider it an able paper and I think that most of the members will agree with its general aim, though I think there are some points we will not agree upon.

John W. Root—I would like to amend so that the general committee have also five members from the Architectural League of New York.

Mr. Burnham—I didn't think that would be advisable, as they are not a national society.

Mr. Bloor (sotto voce)—I don't consider the Western Association a national body.

Mr. Root—The Architectural League is not analogous to any other local architectural society.

Mr. Briggs—That is true. Although the active membership is confined to New York, non-resident members are scattered all through the country.

Mr. Bloor—I was a member of the committee which formed the constitution and by-laws of the Architectural

League of New York. Mr. Burnham is right in saying that legally it is confined to New York. Mr. Root is right in saying that there is an understanding that its benefits should be extended outside of New York if there is any disposition in architects outside of New York to avail themselves of it.

Mr. Root withdrew his amendment.

Mr. Bloor—It was the theme that I suggested to Mr. Burnham to see if we would not unite all the architectural bodies of the country.

Mr. Adler—I would amend that the joint commission constituted by the A. I. A. and the Western Association of Architects shall have power to add to its numbers representatives of other organizations as may see fit to join in the general consolidation of the architectural associations of America.

Mr. Burnham—The work of the committee is solely to get a general scheme to submit to the societies.

Mr. Gibson—Can the committee not be named from those who are members of several associations?

Mr. Adler—As Chairman of the Board of Directors of the Western Association of Architects, I will say the matter has been broached in our board of directors and I believe the entire membership of the board is in favor of an effort at consolidation, and I think they also reflect the wishes of many of the members of the Western Association. There is no doubt that this resolution will be received with favor at the convention of the Western Association which meets next month in Cincinnati. [Applause.] I withdraw my amendment.

The resolution was then adopted *nem. con.*

"Opera Houses" was the subject of the next paper, the writer being J. C. Cady, fellow, of Washington, and the reader L. H. Sullivan, Chicago. An opera house had three requirements—musical, dramatic, and social—and grand opera met the first two. The great expense of grand opera was met, as in Europe by the Governments very largely, so with us by subscribing boxholders among the wealthy and fashionable class, grand opera affording rare opportunity for the display of beauty and toilets. Three considerations must dominate in constructing the building—the stage and accessories, accommodation for a large audience, and special care for boxholders guaranteeing the enterprise. As to the stage it must have large dimensions, like 80x100 feet, and correspondingly deep cellar and high rigging loft. The general audience, occupying a portion of the parquet and tiers above the boxes, they must have spacious, comfortable seats. The exits must be abundant, the building fire-proof, with iron water-tank overhead. Automatic sprinklers were undesirable, as the pipes might burst, destroying the scenery. Regarding accommodations of boxholders, or founders of grand opera, each should have a box, giving seclusion yet allowing display of the occupants. The boxes should accommodate six people, and, to obviate disagreeable possibilities, be similar in style, size, etc. Each box should have a small withdrawing room; for partaking of refreshments, etc.; a long corridor should connect the succession of salons, and a large vestibule and covered driveway accommodate those waiting for carriages that they might be reached with expedition. After constructing such a building in its essentials there would be little money left the architect for aesthetic surplusage in decoration; rather, he must treat the problem with a simple dignity that would not be tiresome as the years went by.

"Prominent Requirements of a Large Library Building" was the subject then discussed by J. L. Smithmeyer, fellow, of Washington. Chief among those requirements, the paper stated, were abundance of solar light, a general provision of artificial light at night, plenty of pure air, a suitable temperature, well-designed protection against the ravages of fire and the deleterious influence of dampness; proper ventilation, convenient interior arrangement, durability of building material, stability of construction. Other considerations also played a most important part. The site should be dry, as great a requisite in a book magazine as in a powder magazine, and proper provision made of the best sanitary arrangements. Nor must the style of architecture be neglected, the artistic combining with the useful to produce the harmonious whole. Foreign models did not meet American requirements, and since we were too young to have our own fixed standards yet, the creative faculty in the individual architect must be called on in a more than ordinary degree. No infallible type could be set up for all locations and circumstances. Most of the large European library buildings sprang into existence, especially the older ones, under conditions differing widely from each other and from the age. Princes and ecclesiastical dignitaries had given palaces and great buildings, requiring much change, and much could be learned by a study of the various novel devices often resorted to. In spite of variations, these buildings could be readily classified into two types—the first the compartment, accommodating at once the books and the readers, and the second separating the two. Small libraries naturally belonged to the first type, but it had its limits, since libraries grew like people and nations. Library construction, as a rule, should proceed on the progressive plan. Dust was the *bête noir* of books, and unless the ventilation movements were downward the dust would rise and destroy the books in the upper tiers. Rapidly changing temperature injured books, as did excessive humidity, and the odor of books and their binding was not healthful, and could not be made more so in one crowded, common compartment. The better plan of separate reading-rooms was being increasingly adopted in the old world and with us, and very widely. The congenial library building illustrated the progressive plan, and its present flexible capa-

city for 2,500,000 books could be extended to accommodate 8,500,000 without enlarging the building. In conclusion, the writer hoped that in endeavoring to be brief he had not been obscure.

Mr. Frederick, of Baltimore, then personally read an essay on the "Dining-Room, its Adornment and Decoration." This apartment was the sanctuary of social intercourse and hospitality, and the table its altar. Direct sunlight should be avoided, especially in summer. Never permit the light to come from more than two sides of the room, and these should be opposite, if possible. Artificial light should come from a chandelier directly overhead, or candelabra on the table; no other light should be permitted unless actually required for the side table. The chandelier must be sufficiently elevated nor to be in the range of vision and yet not so high as to cause unpleasant shadows on the faces of guests. The wall decoration was but the background, and blue being avoided, warm oddish tints were preferable as a foil for silver and other metals and glassware. Oak must always remain the favorite for dining-room furniture. Wainscoting, while generally to be used, should not be too high; an economical substitute was a small chair-rail. Ceiling-panels were always in order, and should be molded in pleasing forms, not too heavy. The walls could be ornamented effectively in diaper, in low-relief plastic. An open fire-place was recommended. Pictures hung upon the wall should have a color background blending into a single tone. Without absolutely prohibiting picture ornamentations, such as sometimes formed a fixed part of the decoration, they must be carefully limited to harmonious themes, as the cycle of the month, the annual sequence of the seasons, agriculture, the sea and its fishes, the subjects always pleasing and cheerful, as taught by examples in Pompeii. Designs and pictures in the ceiling must follow the same rule as for the walls. Portraits of family ancestors were well placed in the dining-room, silent witnesses of the prosperity of their successors. The dining-room, too, was the proper sphere for the display of fine china and silverware, having appropriate admission in the wall and mantel display and sideboard. The carpet or rug on the floor, like the ceiling, should not especially fix the eye, all figures being out of place under foot, and the walls the paramount place for decoration. Carving, excessive ornament and gilding were totally out of place. The table and its toothsome garniture must be left to the hospitable host and hostess and the efficacy of their cook, who in all cases, let it be devotedly hoped, might be a good one.

The chair announced several committees as follows: To express the sense of the institute on the views of Dr. Walter, Messrs. McLaughlin, Smith, and Cutler; to draw up a blank for chapter reports, Messrs. Ricker, Preston, and Frederick; to confer with Western Association of Architects and Master Builders, Messrs. Hatfield, New York; James H. Windemeyer, Philadelphia; Stone, of Providence.

Mr. Gay moved that a committee be appointed, one member from each large city, to indemnify Mr. Bloor for expenses as secretary of the institute. Carried; the chairman Messrs. Holly, Gay, Murdock, Crapsey, Lizius, Van Brunt, Chandler, Stone, Laver, Isaacs, Smithmeyer.

The report of the committee on the directors' report was submitted. Its recommendation of large annual dues was referred to the committee on the proposed consolidation of architectural societies. Chapter secretaries were directed to send in their reports one month before convention. Incidentally, a fellow remarked that the Cincinnati Chapter ought to be reorganized, and Mr. Crapsey, of Cincinnati, replied, "Yes; we will reorganize it out of existence." The committee on permanent home was continued and its three members will be increased to five. The report of the committee on uniform contracts was adopted.

Then quite an interesting debate sprang up, on the

recommendation to continue and add one Western member to the committee on improvement of Federal architecture. Mr. Adler wanted the committee empowered to make such modifications in the draft of the bill as might be deemed expedient to secure its passage. As one of those who went to Washington in behalf of the measure, he came to the conclusion it might be necessary to make modifications—some trivial, some of importance—to render the bill more palatable to those who would have to enact it. Treasurer Hatfield suggested that the Western Association of Architects increase their committee to the same number as the American Institute.

Mr. Burnham—I don't see the use of such a committee. I believe that it cannot accomplish more than the committee previously appointed, and whose efforts resulted in absolutely nothing. To carry out such a reform will require an organization with a great many members in a great many States. There will have to be influences brought to bear to win the Congressmen and Senators, bombarding them with shot from the press, as one of themselves said to me—a high-toned gentleman—and he added that if a Congressman is not compelled by party influence or personal interest he will refuse to act in such cases. I would move as an amendment that the committee be discharged.

Mr. Bloor—I think that nothing will be gained by Mr. Burnham's motion being carried out and that a good deal would be lost. I think there ought to be a committee not larger than five from each society, and that they should be appointed with power—the committee is already appointed with power on the side of the Institute—and that it avail itself of every means at its command to attain its ends. I have received advice from Mr. Hewitt to pursue methods somewhat different from those that Mr. Burnham has been advised to pursue.

Mr. Burnham—I think that Mr. Hewitt's letter, read early in this convention, sustains my position.

Mr. Bloor—Mr. Hewitt does not say that the committee cannot accomplish anything. Mr. Hewitt says it is necessary to enlist one member of Congress; that our only plan is to interest very much such Congressman, make him the father of the bill and make him carry it out. I have advice from other quarters to work through the Secretary of the Treasury and through the incumbent of the office of Supervising Architect of the Treasury. I believe the advice given in each case is good and that we should follow it, and I move that the committee be continued with the modification recommended by this reference committee—namely, that it be added to and continued with power and do the best it can in conjunction with the joint committee appointed by the Western Association.

Mr. Adler—I move that the joint committee endeavor to avail itself of the ideas expressed by Mr. Burnham.

Mr. Bloor—My own personal opinion is that we must manufacture public opinion through the press.

Mr. Burnham—I don't want the bill tossed about in Washington so that men will become disgusted with the thing. With a strong organization, with a thoroughly consolidated organization where the committee has a work with men from every State and they can be sent out to do hard work, the reform will be started directly. Then I think we must have somebody in Washington to see that it is done. I don't mean lobby, although that is what it amounts to. It should be honest work, open and above board; but it is necessary that some one should be there in our interest to see that it is brought up and forced to a passage. Good bills which all acknowledge should become laws are only passed by Congress when there is somebody there who is particularly determined that they shall be passed. That means that we must employ somebody or that some member of this association should go there and stay until the work is done. I would rather not see demands made which I know will be abortive before

they are started. When the next demand is made I would like to see it carried right through to success. But that means that we must do a great deal of thinking, a great deal of planning for it.

Mr. Adler—It is not the first time that good measures have been held in abeyance. If it is really our desire to secure the passage of this bill, we must not be discouraged with a repulse. I think the abandonment of this committee would be considered by the profession as an acknowledgment of defeat; that we recognize the fact that we have been defeated; that it is all no earthly use to endeavor to push the work we have in hand. We should undoubtedly maintain this or some other committee whose duty it is, not simply to go to Washington and interview a few Congressmen there, but to endeavor to make use of every possible means, through agitation, through the press, through interviews with enough members of Congress, through every auxiliary at command to secure the end for the attainment of which we are striving. It will be the duty of the committee to set in motion the very machinery which Mr. Burnham thinks so desirable. I think it easiest to maintain the committee.

Mr. Burnham's amendment for discharging the committee was then rejected and the committee continued.

The other recommendations in the directors' report were then adopted.

Adjourned for lunch in the ante-room.

On reassembling the convention sat for over an hour with closed doors on a case of discipline and the matter was referred to the Board of Directors. Then followed the usual votes of thanks all around, and Mr. L. D. Cleveland, who was in the chair, declared the convention adjourned.

ARMORY ROOF, BUFFALO, N. Y.

The roof of the Seventy-fourth Regiment Armory Building, Buffalo, N. Y., Mr. George J. Metzger, architect, was built and erected by the Niagara Bridge Company.

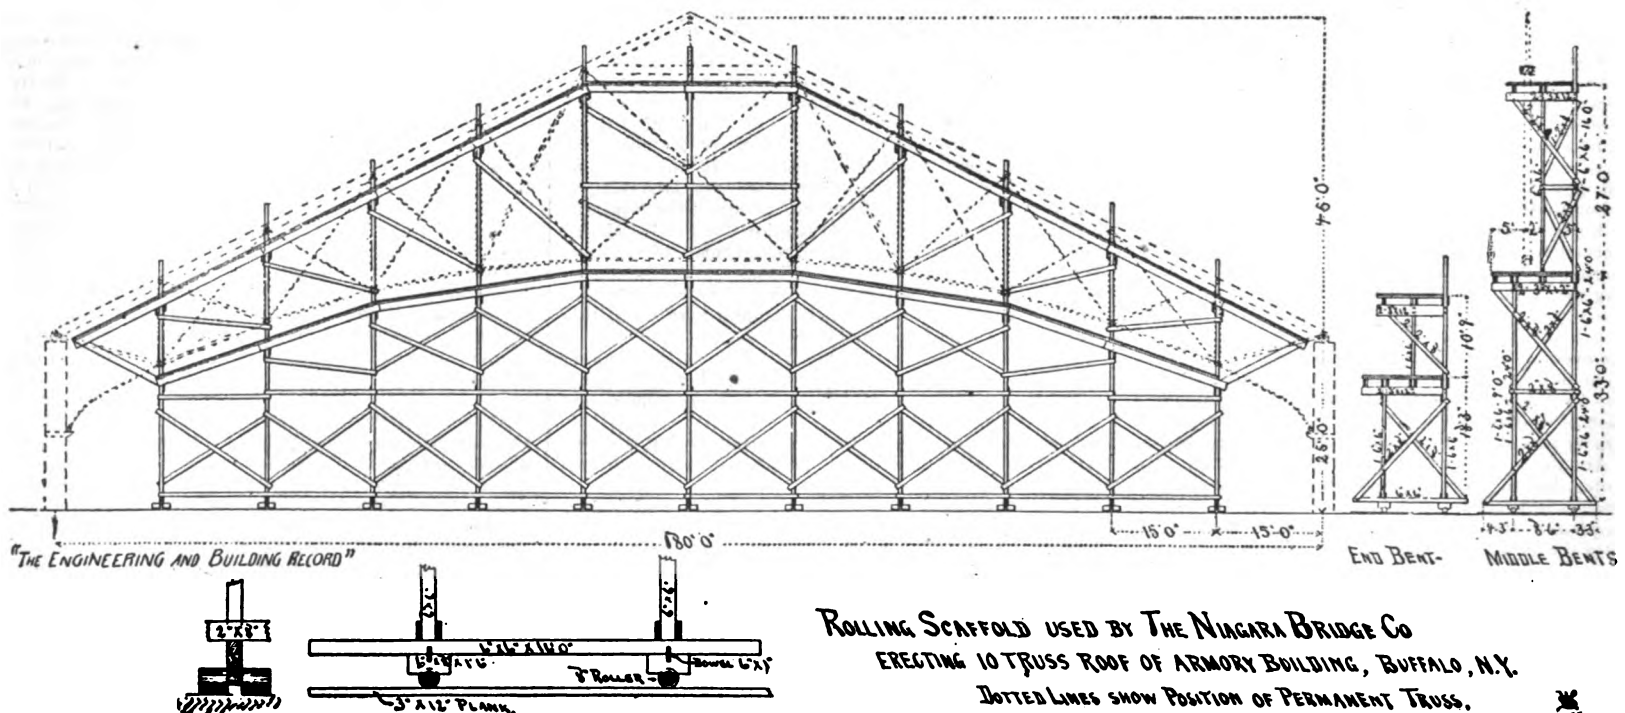

It consists of 10 trusses, 180 feet span centre to centre of end pins, spaced 25 feet 3 3/4 inches centres, with top chord lateral bracing in alternate panels.

The metal weight of trusses is 120 tons, and there are 128,000 feet, B.M., of Norway pine in trusses and purlins.

All tension members are round, and square rods or die-forged eye-bars (the latter made by Union Bridge Co.) of high-test double-refined iron; connections carefully bored to gauge.

The trusses are bolted to the walls and have expansion rollers at one end to provide for the 1/4-inch movement that the extremes of temperature in this locality causes.

The trusses in position are very stiff, and the pleasing effect is improved by the pair of curved eye-bars that continue the arch-like line of lower chord from the foot of the first vertical post to a bracket half-way down the face of the wall. These bars are precluded from exerting any strain during temperature, oscillating by the slotted hole connection at the foot. An interesting feature of the construction of this roof was its very rapid and economical erection from a movable scaffold carrying upper and lower platforms, as shown in Fig. 2, that was mounted on rollers and transferred from one truss and adjusted in readiness for the succeeding one in half an hour. It was originally

attempted to lay the corrugated-iron roofing directly upon the purlins, which were spaced for that purpose, but this was found undesirable, and a board sheathing was laid as for shingles. The fastenings of the corrugated sheets are still troublesome and loosened by temperature changes.

The armory walls are brick, buttressed at each truss, seat and foundations carried down to solid rock, and as the total cost of building, excepting roof-sheathing boards, was only \$50,000, the roof is of interest as well for its cheapness as for a neat and light example of an unusually long span combination roof-truss.

EADS' LAST WORK.

ABOUT February 1, 1887, Mr. Eads, then in New York, sent for Mr. H. W. Brinckerhoff, now of the editorial staff of THE ENGINEERING AND BUILDING RECORD, and desired him to revise the designs for the ship-lifting appliances of the Tehuantepec Ship Railway which he had made for Mr. Eads nearly four years before. Giving him some verbal instructions and a few rough pencil sketches, reduced about one-half in the accompanying facsimiles, he sailed almost immediately for the Bahamas, hoping there to recover his health, never robust, and then much impaired by his incessant labors in behalf of the Ship Railway. Before leaving he desired that tracings should be sent him in about a fortnight showing the progress made on the revised plans, and it is to the tracings of these plans that allusion is made in the following letter—perhaps the last he ever wrote, certainly the last of a professional nature, as his death occurred on the 8th of March following. It is interesting to note the progress of his thought in this letter, each suggestion showing a distinct advance, until a final and satisfactory conclusion is reached.

The sketches, though hastily made by an invalid's hand, give evidence of careful thought and much attention to detail. They do not correspond very closely with the letter, several changes in the size, number and arrangement of the rams having been made meanwhile. It must be remembered, also, that the sketches show mainly the ship-lifting platform, while the letter relates almost exclusively to the counterbalancing tank on shore, both tank and platform resting on rams of equal aggregate displacement, and so connected that as the platform rises the tank descends, and *vice-versa*.

The interest of these documents, apart from the distinguished character of their author, lies in their relation to the cardinal feature of the most daring and gigantic project of modern times.

ROYAL VICTORIA HOTEL,
NASSAU, N. P., BAHAMAS, February 25, 1887.

DEAR MR. BRINCKERHOFF:

I am much pleased with the plans you sent me so far. Make the rams 30 inches in diameter, the whole 32 of them. This will enable us to pack them with leather, which is much more reliable for 1,500 pounds than hemp is for 600, I think.

The 16 rams on shore should be put in a circular pit 60 feet diameter, lined with a concrete wall averaging 4 feet thick, started on a bed of concrete 80 feet in diameter and 10 feet thick, commenced 40 feet below low-water mark. On this bed cast-iron bed-plates well ribbed must be bedded for the cylinders to stand on. These 16 rams will support an iron tank capable of holding enough water to raise the platform, 1,200 tons; the ship, 4,000 tons; the carriage, 600 tons; total, 5,800 tons. The two sets of rams will balance each other in weight.

This tank had better be circular and made of $\frac{3}{8}$ -inch plates. It should rest on a cast-iron plunger head, into which the plungers should be accurately socketed about one foot deep. As this head and the empty tank will weigh less than the platform, the latter will always raise the tank and its plungers and head. When the tank is filled with water it must hold enough to bring up the ship, platform, and carriage.

I think we can get head enough in the Coatzacoalcos River within fifty miles to fill this tank rapidly with a flume six feet square, but we will provide sufficient pumping power to fill it in half an hour, and not depend on the former until we know that we can get it.

I suppose sixty feet diameter by fifty feet high for the tank will be sufficient. It must be guided in its ascent, and it should be so arranged that when empty it can be lowered down on rails or slides and moved off so as to give

convenient access to the rams and plungers. A reservoir must be provided near by into which its contents can flow rapidly through a telescopic pipe or pipes, and from which our pumps will return it to raise the platform. On the railway provided for the tank there should be a moving or travelling crane to handle the rams, etc.

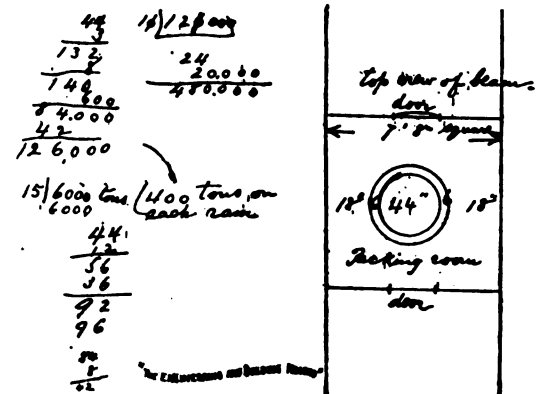

Of course, this plan admits of many modifications, and I wish you to make several which will suggest themselves to you and find such one as will admit of the simplest details and most economic construction, keeping the data from which you estimate approximately the cost of each,

and putting it in such convenient shape as you can for future reference. For instance, you may find it cheaper and better to sink down four iron cylinders as casings in which to place four rams each, instead of putting all sixteen in the concrete chamber described. Again, it may

be better to have the rams stand higher above ground and pass through the tank, each through a separate cylindrical opening in the tank in which each ram-cylinder would act as a guide for the tank. Or, four such cylinders (rams) could be clustered together in one such opening through the tank (four openings in all). The tank could be suspended by cross-heads on each plunger and would be so shallow as to expose the plunger-heads above it when down, so as to give easy access to any one ram, and thus make it unnecessary to ever remove the tank. The cylinders or their rams if leaking would be packed on the top of the tank or lifted out of their casings up through the tank for repairs.

You may find it best to shorten the stroke and increase the diameters of these shore rams to save pumping the water so high in the tank, in which case the capacity of the tank must be increased. I want leather packing, and this would limit their diameter to probably thirty-six inches. It may be better to double the number and give

them only half stroke, making each pair of the thirty-two fill one cylinder under the platform. This would greatly reduce the height to which the water would have to be pumped up, but would require twice as much tank area to give the necessary pressure.

I do not wish to confine you rigidly to either one of these modifications. Make enough sketches to determine which is best and follow that one out in all its details.

Show this letter to Mr. Corthell and he may be able to advise you when in a dilemma about the plan.

Yours sincerely, JAMES B. EADS.

My health is rapidly improving.

THE NEW CHICAGO WATER TUNNEL.

Abstract of specifications for the construction of a water tunnel eight feet in diameter, from a point on the Lake Park in Chicago to be built in an easterly direction under the bed of Lake Michigan, to a distance of about four miles.

THE Lake Park shaft may be built, at the option of the contractor, either by timbering the excavation to the bottom before commencing the masonry, or by building the upper portion on an iron shoe, to be sunk by excavating the earth within to the required depth. In either case the shaft must be lined with brick masonry not less than sixteen inches thick.

There shall be one shaft at the end of the tunnel and one shaft intermediate to hasten the completion of the work. These shafts shall be protected by suitable cribs; the method of construction of these cribs will be left to the contractor, subject to the approval of the City Engineer, but the contractor must be responsible for their safety, and must maintain them during the progress of the work. The interior well of the cribs must be kept free from water at all times, and he must also remove them and clear away all remains and rubbish after the work is completed.

The shafts shall be cast iron, ten feet in diameter, and the metal $2\frac{1}{4}$ inches thick. The upper end of the inlet cylinder shall be capped with a bell-mouthed casting, covered with a cast-iron perforated plate, strongly ribbed. After the crib around the bell-mouth inlet has been removed the bottom of the lake around the casting shall be covered with a concrete of one part best English Portland cement, two parts sand, and four parts broken stone.

The clear width of the tunnel inside shall be eight feet, and the clear height eight feet and two inches; the top and bottom arches shall be semi-circles; the tunnel shall

be lined with brick masonry thirteen inches thick. The ground through which the tunnel proper is to be built is believed to be firm clay, with pockets of sand or gravel and water, and occasional boulders, with rock on and near the shore. From the lake shafts the contractor must remove all excavated material to such point as shall be designated, not exceeding one mile from any shaft.

The cement used in this work shall be equal to the best of Black Ball Brand of Utica cement. Where the tunnel is in rock the brick lining may be reduced to one ring of brick.

The Commissioner of Public Works reserves the right to end the tunnel at two and one-half miles from shore, or to extend it to the full length of four miles, as he may elect.

If the tunnel is to end at the first lake shaft, two and one-half miles from shore, the whole of the work shall be finished and completed ready for use within 42 months after signing the contract.

If the Commissioner of Public Works elects to extend the tunnel to four miles, this part of the work must progress at the rate of not less than 1,800 lineal feet of tunnel per year from each working face.

Bids will also be considered for an iron tunnel. The metal shall not be less than $1\frac{1}{2}$ inches thick. This shall be lined with bricks or other material equally good. The top of the tunnel at a distance of four miles from shore shall be not less than 50 feet below city datum and at the shore line not less than 54 feet below city datum.

Proposals for the above work will be received until 11 A. M., Monday, November 7, 1887, by George B. Swift, Commissioner of Public Works, Chicago, Ill. Proposals must be made out on blanks furnished by the Commissioner, and accompanied by a deposit of \$50,000.

The accompanying illustrations show only the shore shaft and lake inlet. The construction of the intermediate shaft is very much the same as that of the lake inlet, except that depth of water is but 40 feet and that bottom of tunnel is 78 feet below datum. The crib, temporary working shaft, and sump are the same, the strainer of course being omitted. On completion the sump and so much of the working shaft as cannot be removed are to be filled with brick and concrete, leaving only the bore of the tunnel.

THE EFFECT OF TEMPERATURE UPON STRUCTURAL IRON AND STEEL.

BY JOSEPH RAMSEY, SR.

STYFFE, Fairbairn, Kirkaldy, Webster, the United States Government Commission, the Railroad Commissioners of Massachusetts, and others, all hold that the effect of low temperature upon iron is very slight, and that it does not tend to produce a brittle condition. Sandberg is the only one who claims that low temperatures have any pronounced effect in producing brittleness—that is, he is the only one among the recognized authorities; but if you have ever been out in the woods on a cold, frosty morning you may have noticed that the axeman warms his axe before beginning work; ask him why he does so: he will reply, "to take the frost out."

Watch the trackman on a cold morning. He is very careful not to strike his cold-chisel too hard, and neither does he cut so deeply into the rail, before dropping it to break it, as he does in warm weather. Ask him why: he will say, "the chisel and rail are full of frost, and will break more easily than in warm weather." The same thing will be noticed with the men who are unloading steel rails, or

usually. On the contrary, I believe it is increased slightly due to the hardening effect of the low temperature, just as tempering and hardening of steel or iron increases the ultimate tensile strength. In preparing for our tests I stated my belief as above, and I found it supported by the tests for tensile strength in the testing-machine. When we come, however, to examine into the strength of iron to resist sudden shock or impact when it is exposed to low temperature, we obtain surprising results, such as seem to call for more thorough and exhaustive tests than have heretofore been made.

The tests made for tensile strength and elasticity showed that there was no decrease in either strength or elasticity under gradual stress; if anything, there was an increase in both. The character of the fractures showed that the low temperature still caused crystalline fractures. In all the tests below 10 degrees Fah. there were from 10 to 15 per cent. crystals, while above 10 degrees temperature every fracture was 100 per cent. fibrous.

The tests by impact were made by a drop weight falling upon a pin, two inches in diameter, which rested over the groove cut in test piece.

I believe that at 15 to 20 degrees temperature the resistance to impact is not more than 25 to 30 per cent. and that for temperature as low as 0 to 10 degrees not more than 10 to 15 per cent. of the resistance at 70 degrees; and at such low temperature as 20 degrees Fah. it is nearly in the condition, as regards brittleness, of cast iron.

During my investigation of this question, Mr. Hunt gave me an account of the breakage of a 12-inch channel beam during the erection of a large highway bridge in the North-west, by it falling a distance of 10 feet and striking a post, the 12-inch channel breaking short off with 80 per cent. crystalline. Mr. Hunt was called on to make an inspection of the beam, and, as the temperature at the time of the breakage was zero degrees, he thought it a good opportunity to test the question of effect of temperature. He had inspected the iron at the mills and knew it to be good ductile iron. Specimen pieces were cut out adjoining the break, and two taken into a shop and warmed up to 70 degrees. In the bending test the iron closed on itself, and the nicked bending test gave 100 per cent. fibrous; the other two specimens were placed outside with temperature of zero degrees, and after being cooled down to that temperature were tested, and both gave 100 per cent. crystalline.

The following questions are suggested to me by the result of my tests, and I think a discussion based upon them will bring out all there is in the matter generally:

First—Should a temperature be prescribed in specifications at which the nicked bending test for texture shall be made, or at which the iron should show good fibrous iron?

Second—Is the present method of testing iron for ultimate strength, elastic limit, and elongation calculated to secure the best iron for bridge-work?

Third—Should not an impact test by drop weight be added to the tests?

Fourth—Is it safe to run trains over iron bridges at high speed when the temperature is low, say 15 above, and if not, what should be the maximum speed at such temperature?

I wish to acknowledge and give credit to Mr. A. E. Hunt for the aid and assistance given me in these tests, also services of Mr. F. Beresford, C. E., of Cincinnati.

[The paper brought out a discussion by Messrs. Becker, Barnes, Hibbard, Hunt, Frank, Hallsted, and Osborn. The "Question Box" was opened for the first time and bids fair to be of great interest. The discussion of Mr. Ramsey's paper will be continued at the next meeting. President Dempster occupied the chair.]

NEWPORT'S SEWER SYSTEM.

DOUBTS have existed in the minds of certain Newport people as to the level of Newport's main sewer. Next month the taxpayers will vote on the expenditure of \$100,000 for the completion of the sewer system, and as a wise preliminary the Committee on Streets and Highways have invited Colonel George E. Waring, Jr., Professor Furman Rogers, and Mr. Charles E. Hammett to examine and report on this disputed point.

ERRATUM.

WILLIAM R. BILLINGS, C. E., requests us to say that in article on "Some Details of Water-Works Construction," No. III., on page 583, 42d line from top of second column, the sentence should read, "the worst cases that have been," etc., instead of the *most* cases, etc.

wheels and axles: they are more careful to let them down easily in cold than they are in warm weather.

You may say, but that is only a popular fallacy. It may be so, but these men have had some experience which has led them to this opinion, and I am afraid that there is more truth than fallacy in their claim that "frost in the iron makes it brittle."

During the past winter I wrote to a number of eminent bridge engineers and inspectors, submitting these questions:

First—Do you prescribe any temperature for nicked and bending tests?

Second—Does temperature affect the texture of iron; that is, will iron be more crystalline at low than at high temperature?

All the replies received were unanimously in the negative, and I concluded to make some tests.

I made a large number of nicking and bending tests by hammer (as generally required by specification), and the fractures obtained invariably were largely crystalline under low temperature and fibrous at high temperature.

As regards the effect of temperature upon the tensile strength of iron, I do not believe that low temperatures reduce the ultimate strength, when the load is applied grad-

DOMESTIC ENGINEERING, ETC., IN THE
EQUITABLE LIFE INSURANCE BUILD-
ING, NEW YORK CITY.

No. IV.*

(Continued from page 585.)

THE BOILERS.

THE 14-inch steam-main is composed of cast-iron flange-tees to receive each boiler branch, and the spaces between filled up with the kalamein pipe manufactured by the National Tube-Works Co. This pipe is comparatively a new article of manufacture, and is claimed to give protection against the corroding influence of salt, the protective agent being known as kalamein alloy. It is tested to 150 pounds per square inch of surface. The flanges are fastened into place by an expander.

Figure 3 also gives a side view of the boiler-setting. It will be noticed that the ash-pit is much lower than the floor-level. This was done for the purpose of making a water-pit of six inches depth and over, enabling the fireman to make a day's run without cleaning and still have as large an ash-pit area as ordinarily kept. The space between the bottom of the combustion-chamber and the bottom of the boiler is two feet, or just coincident with the height of the grate-bars.

The back connection, arched as shown at E, sustains the brick-work without the aid of metal supports that are apt to burn out. The space between the sides of the boiler and the brick-work ends three inches below the water-line.

The boilers are covered over with specially made fire-proof blocking.

The walls are built on either side of each boiler about sixteen inches higher than the top of the boiler, then wrought-iron beams of T-section inverted laid across from wall to wall. The blocks of material, 4x13x20-inches, rest on the projecting lips of the inverted T-irons. The bottom side of this layer of blocks is within one inch of the boiler at the nearest point. In addition to this another layer is laid eight inches higher than the first, forming an 8-inch air-space between the two layers beside the air-space formed immediately on top of the boiler by means of the first layer; in other words, making *two* air-spaces above the boiler instead of the usual single air-space. The blocks of fire-proof material were specially made for the purpose.

The boilers are built in continuous brick-work, with no passageway between except air-tunnels running from front to back coincident with the position of the columns of the building which occur between each pair of boilers. These are encircled with brick-work, particular attention being given to having large air-spaces between that connect at their bottom ends with the air-tunnels mentioned.

Air-spaces are formed in the walls where available, and pieces of pipe left in the outer walls to carry off the moisture while the brick-work is drying out. The space from the bottom of the boiler to the top of the grate-bars is two feet. The bridge-wall, twenty-four inches thick, is built square across and measures ten inches to boiler at centre. It is built of ordinary fire-brick to within a few inches of the top and coped with large "pier" brick for stability. The width of the back connection is twenty inches.

SMOKE-STACK.

The smoke-stack is made of plate steel in sections ten feet long; the diameter is six feet, and height 170 feet above the sidewalk. The method of joining the sections is by circular castings of angle-iron pattern riveted to each end of each section and bolted together in the rough. The five bottom sections are $\frac{1}{2}$ -inch thick, the next five $\frac{3}{8}$ -inch, and the upper seven sections $\frac{1}{4}$ -inch thick. A ring of wrought iron 3x $\frac{1}{2}$ -inch is riveted around the top for appearance and strength. The weight of the stack is upheld by a base casting of special construction designed by the superintending engineer and shown in Fig. 4.

C is a cylinder of cast iron two inches thick and thirty-

*No. I. of these articles, containing the first installment of Sketches of Plumbing, appeared in our issue of October 8; No. II., General Description of Building and Plant, October 15; No. III., Details of Pumps and Boilers, October 22.

six deep, large enough to take in the bottom section of the stack S. A flange, P, stiffened by brackets, W, extends around the cylinder twelve inches from the top; the flange rests upon 15-inch I-beams at four points, as seen in Fig. 4. Riveted on the stack, six inches from the bottom, are eight strong wrought-iron lugs or feet which rest directly upon the upper rim of the cylindrical casting; thus the whole weight of the stack is borne and transmitted from lugs to castings, thence to I-beams, which are made long enough to rest on the adjoining walls. The stack is kept vertical in the shaft or well provided for it by two 6-inch I-beams running east and west at alternate joints and north and south at those intervening.

The relative position of stack to battery of boilers is at the back and to one end. The connection between boiler and stack consists of a suspended flue of rectangular shape which passes overhead along the back of the boilers of increasing area as it nears the stack. This main flue receives the smoke of each pair of boilers by means of smaller flues running along the top of the boiler brick-work from front to back, the same being in each case a prolongation of the ordinary breeching. Three tight-fitting hinged doors, opening downwardly, are provided on the under side of the main flue for purposes of entry. The rectangular shape gradually comes to a round ending in the large 6-foot elbow shown in Fig. 4, which in turn is bolted to a flange cast on the lower end of the base casting.

SUPPORT OF SMOKE STACK

FIG. 4.

A damper is placed in the breeching immediately over each furnace-door to shut off each pair of boilers when necessary, and in addition a large steam-regulated damper is placed in the main flue immediately behind the large elbow. Where the smaller flues enter the main flue a deflecting plate directs the flow of the gases toward the chimney. The arrangement works well.

BOILER-FRONT.

The boilers are fitted throughout with Ashcroft doors and grate-bars. These grates have been in use in the old part of the building for nine years, and have given good satisfaction. The bars are made of rolled steel cut into equal lengths suitable for various sized furnaces. The cross-section of each bar is that of a triangle with the angles rounded off and the sides slightly curving between the points. They are not connected to each other by a rocking attachment, but pass separately through holes in the boiler-front immediately below the dead-plate, and are made long enough to reach from the front side of the bridge-wall to a point four inches beyond the boiler-fronts, enabling the fireman to grasp each bar with a suitable wrench, and rocking it much or little or revolving clear around if thought necessary.

The bars are borne by bearers set about eighteen inches apart and scalloped on the top side to suit the pitch of the

bars and keep them in place when shaken or revolved. The revolving of the bars grinds out the ashes from the bottom of the fire, leaving it light upon the grate and in condition to permit the air to pass into the interstices of the fuel, avoiding the necessity of using a slice-bar with the anthracite coal in use. By this arrangement the engineer says all parts of the furnace are equally cared for, the remotest corners getting the same attention as the nearest. The intended air-space is well preserved, as the bars can be turned upside down as often as the fireman chooses, a feature which permits of constantly presenting different faces of the bar to the heat.

The approach of the air to the spaces between, it is claimed, is greatly facilitated, as is also the descent of the ashes. By turning each alternate bar with the point up while the others are turned down a much larger air-space is secured than with the points all down as in regular use.

The coal used in the building is "grate size."

The furnace-door is hinged upon the furnace front in the usual way, and, when necessary—as in firing—may be thrown wide open so as to expose the full size of the opening into the furnace; but as regards other purposes it may remain closed. A sectional elevation of this furnace-door was shown in Fig. 3. A rectangular central part of the door A, nearly corresponding with the fire-door opening is cast separately and hung upon horizontal pivots. It is so nearly balanced as to remain in any desired position, the friction on the trunnions being enough to hold it.

The pivoted portion of the door is made double—that is, with an outer and inner wall held to each other at the sides, but having a narrow slit B at the top open to the atmosphere, and a wide slit C at the bottom opening to the furnace, forming a passage through which the air to the furnace enters if desired. The air in passing downward between the inner and outer plate or wall is heated considerably as it comes in direct contact with the plates. The inner plate is corrugated, and, by radiation, transmits much of its heat to the outer plate.

The furnace-door usually does not require to be opened except for firing. In the manipulating of the fire, as by the introduction of a poker to break up the congealed mass which accompanies the burning of soft coal, the furnace-doors do not require to be opened. Neither does the pivoted part of the door to a greater extent than sufficient to introduce the poker under it, while at the same time the fireman is enabled with little inconvenience from the heat to examine all parts of the fire and note where it requires replenishing. This he can do by swinging the top of the pivoted door outward. The arrangement admits of regulating the amount of air needed admitted above the fire for burning various kinds of coal.

PASSENGER ELEVATORS.

The building is supplied with ten hydraulic passenger elevators for public use, built by McAdams & Cartright, 57 Elm Street, New York.

They are situated in groups of two in five separate wells or shafts. Nos. 1 and 2 are placed in, and open directly off, the Nassau Street entrance; four are placed in the entrance hall leading from Pine Street, two on each side of the hall, numbered 3, 4, 5, and 6; four are placed on the opposite side of the main corridor in a recess facing the Pine Street entrance, numbered 7, 8, 9, and 10; nine operate from the basement or ground floor to the eighth story, a distance of 135 feet; one has an additional fifteen feet of car travel, and operates from the cellar to top floor, a distance of 150 feet.

WATER-SUPPLY.

The water-circulating apparatus for these elevators consists of the two large tanks, P P in cellar plan, and the three duplex-pumps B B B, with their connections, in the cellar, and fire-pressure water-tanks placed on top of the building above the highest point of car travel. The same water is used over and over.

The water-tanks shown at P P (cellar plan) are open on top; their surface area is 12'x11'x11'6". They have a united capacity of 15,000 gallons. A clear space is left under them for access to joints, etc. They are made of $\frac{1}{8}$ -inch iron.

The three duplex plunger-pumps, shown at B B B (cellar plan), were furnished by Henry R. Worthington, New York, and are designated "compound steam-pumps, 18 $\frac{1}{2}$ inches and 29 inches diameter of steam cylinders, by 16 inches diameter of water-cylinders, by 18-inch stroke of plungers.

The overhead pressure water-tanks are 14 feet long by 6 feet diameter; have dished or bumped heads; they are

made of $\frac{3}{8}$ -inch iron, provided with manholes double-riveted in the longitudinal seams, and tested in all respects like ordinary boilers. They rest on cast-iron saddles placed near the end, and are sustained in position by 15-inch I-beams, which, in the case of elevators 3, 4, 5, 6, 7, 8, 9, and 10, span the space represented by the Pine Street entrance and the recess opposite. The pair of tanks supported by each set of beams are connected so as to maintain uniform water-level as nearly as possible.

CONNECTIONS.

The suction-pipe between the tanks P P, and steam-pumps B B, is placed in an open-walled subway. The pipe is of cast iron throughout, is 20 inches diameter, and $\frac{3}{4}$ -inch thickness of metal. Special 20-inch angle-valves, with soft disks, were designed and manufactured by Jenkins Brothers for this pipe, their weight being 2,860 pounds each. A tee is placed opposite each pump, with flanges looking upward, on which are bolted 14-inch angle-valves, with vertical flanges, connecting with the 14-inch Y-branches peculiar to the Worthington pattern. The office of these valves is to shut off any single pump from service.

The discharge-pipe C C is 15 inches diameter. This pipe, although 16 inches diameter, is made of only $\frac{1}{2}$ -inch material tested to a pressure of 150 pounds per square inch. It is necessarily overhead, and is chosen of this material for its extreme lightness of section. Branches 51, 52, 53, 54, and 55, of wrought-iron pipe, 10 inches diameter, discharge the circulating water into the several tanks at the head of the elevator-wells, one 10-inch pipe to each tank or pair of elevators. Each branch is provided with an independent gate-valve near the discharge-main, also a means of draining the branch into the open water-tanks P P.

The water from the overhead tanks to the elevator cylinders is returned, under pressure, through wrought-iron pipes 6 inches diameter, an independent pipe to each elevator. A gate-valve is placed on each pipe near the tanks for purposes of disconnecting any elevator from the service.

The idea of isolating any elevator or member was constantly kept in view, and is provided for not alone in the elevator service, but throughout the engineering department of the entire building.

The pressure-tanks being five in number, and placed near their work, instead of having one central tank, avoided the necessity of heavy supports at any one portion of the building, the necessity of stopping for a leak, also the leading of pipes across the roof, which would be in the way and liable to burst from the effects of frost.

The tanks being placed at a point about 150 feet above the hydraulic cylinders of the elevators gives a natural hydrostatic pressure of about 64 pounds per square inch on the pistons. In addition to this pressure, the pumps are run at a speed that insures a forced pressure in overhead pressure tanks of about 20 pounds per square inch. A Locke automatic regulator of the entering stream governs the speed of the pumps, so that the pressure of about 80 pounds is preserved at the hydraulic cylinders with but slight fluctuation. An air-chamber is maintained in the top part of each pressure-tank, its shape being a chord of a circle about ten inches in vertical height at the highest point.

(TO BE CONTINUED.)

A WASHINGTON PLUMBING REGULATION DECLARED ILLEGAL.

(From the Washington Star.)

The Commissioners compelled to issue a permit to Mr. Hannan—The recently promulgated regulations declared to be beyond the authority of the Commissioners—Judge James thinks there ought to be a law.

In the Court in General Term to-day an opinion was delivered by Chief Justice Bingham in the case of the United States, *ex rel.* Daniel Hannan against William Ludlow, Engineer-Commissioner of the District, which probably renders void the regulations recently adopted by the Commissioners requiring plumbers to be examined before registration, and imposing other requirements upon plumbers before permitting them to engage in business as a plumber. The case came before the Court on the petition of Mr. Hannan to compel the Engineer-Commissioner to issue a permit to him to make the necessary excavation to introduce water into premises 822 Twelfth Street northwest, his application for such permit having been refused on the ground of non-compliance by Mr. Hannan with a certain regulation made by the District Commissioners April 23, 1887. The petitioner alleged that the requirements of the regulations made last April were made without authority; that they are unreasonable;

that they are in restraint of trade, an invasion of the relator's right to pursue his craft; that they are inconsistent with the common law, and are an invasion of the right of property, and that they impose on the relators burdens from which other trades are free.

THE ACT OF CONGRESS.

Chief Justice Bingham, in announcing the opinion of the court said these regulations were based on the act of Congress approved January 25, 1881, authorizing the employment of an inspector of plumbing, and investing the health officer with authority, under the direction of the Commissioners, to execute and enforce regulations governing plumbing, house-drainage, and the ventilation of house sewers, and providing penalties to be imposed upon persons neglecting or refusing to comply with such regulations when promulgated. In November, 1882, the health officer made certain regulations providing for the registering of plumbers, and the issuing of permits to make excavations, etc. The petitioner, alleging that he has complied with the regulations of November, 1882, sets forth that on the 1st of September last he made application to introduce water in the house 822 Twelfth Street, and permission was refused, and is still refused, on the ground of non-compliance with certain other regulations made April 23, 1887, by the Commissioners, purporting to be issued under the same act. It was these regulations that the petitioner claims are

WITHOUT AUTHORITY OF LAW.

unreasonable, and an unwarranted interference with his rights. It was also claimed that the order of the Commissioners of May 4 last, requiring plumbers previous to registering, to deposit \$3 as a registration fee, was not warranted, and imposed a burden on the plumber not imposed on other trades. Chief Justice Bingham included in his opinion the rules and regulations promulgated April 23 last, which among other requirements prescribe that no person shall be allowed to engage in the plumbing business or to do any plumbing-work whatsoever relating to the water-supply or drainage of premises in the District except a master plumber who shall have duly registered or an employee of a duly registered master plumber; and that no plumber shall be allowed to register until he shall have passed a satisfactory examination by the board constituted for that purpose. It is also required as qualifications for registering that the candidate shall be twenty-one years of age, a citizen of the United States for at least one year previous to his application, and be certified as a man of intelligence, good habits and character, by at least three responsible citizens. No objection was made by the petitioner, the Chief Justice said, to the regulations of November, 1882.

THE POWERS OF THE COMMISSIONERS.

The first objection to the regulations of April last was that the Commissioners had no power to make such regulations, the health officer being by the act of January 25, 1881, exclusively empowered to make them. The court held, however, that as the health officer can only execute and enforce such regulations as the Commissioners direct, the Commissioners must first direct what the regulations shall be. The court, therefore, did not sustain this objection. The other point made by the petitioners was that, conceding that the power to make such regulations resided in the Commissioners, the regulations in question are in excess of their legal authority, and therefore void. The court was not, the Chief Justice said, unmindful of the gravity of the question before it. The regulation of plumbing in its relations to the health of the community undoubtedly called for the wise exercise of all the powers possessed by the municipal authorities. On the other hand, the rights of citizens could not be invaded. He quoted authorities to show that municipal corporations only possessed such powers of regulation as were necessary to enforce powers specifically granted by law, and that an order cannot be made to contravene common law.

THE EXAMINATIONS UNWARRANTED.

The Chief Justice then summarized the requirements prescribed by the new regulations as necessary before a plumber could be registered, and said that the scheme to test the qualifications of a plumber was not warranted by the Act of January 25, 1881, authorizing the appointment of an Inspector of Plumbing, etc. The Court's construction of this act was that the regulations authorized by it applied not to the plumbers themselves, but to the work done by the plumbers, or, in other words, it was intended to secure good plumbing. This, the Court thought, was the entire scope of the statute. Nor did the Court think the Commissioners had any such power as these regulations applied conferred upon them by other acts referred to in the argument of the case, the acts relating to the control of streets, etc., it was not intended by Congress to grant such power. The Court reached this conclusion reluctantly. It may be that the Commissioners should possess the power they have attempted to exercise, and, if so, an appeal should be made to Congress. The Court's attention had been called, the Chief Justice said, during the examination of the case, to the act regulating steam-engineering in the District. The provisions of this act and the plumbing regulations issued by the Commissioners are so similar in structure that the suggestion at once comes to mind that these rules and regulations were patterned after this act. To the Court it seemed that the fact that Congress found it necessary to pass such an act in relation to steam-engineers suggested that the power should come also from Congress to enable the Commissioners to pass such regulations respecting plumbers.

JUDGE JAMES IN FAVOR OF A NEW LAW.

* Judge James said he would like to add what might be an extra-judicial opinion. They were, he said, in the hands of the plumbers just as they were in the hands of the druggists. Both can poison them. It would be an extremely desirable thing if some one would have such a law passed as the Commissioners had framed respecting plumbers. Such regulations he deemed necessary. Whatever the Commissioners did, he said, was apt to be criticised as an act of tyranny. In this case he was sorry they have not the power to make the regulations. The Court recommended the mandamus to issue.

VIOLATIONS OF THE PLUMBING AND TENEMENT-HOUSE LAW IN NEW YORK CITY.

THE accompanying cut illustrates another of those unaccountable plumbing blunders, so often discovered by the Board of Health when called into premises where alterations have been made by careless or ignorant persons.

In this case a number of houses on Ninety-fourth Street, near Lexington Avenue, have two overflow-pipes to each house-tank. The overflow *a* was probably first put in and connected with the vent-pipe of the water-closet trap, itself being untrapped. This let the stench into the house-tank. Then, presumably, a plumber was called who put in the

second overflow *b*, to the bath-tub, which is right enough in itself, but he either forgot to cut off the first pipe *a*, or he plugged it, thinking that sufficient, when some one following him removed the plugs, letting the sewer-air into the house again. What makes this matter worse than ordinary is the fact that the house-drains enter a private sewer through the cellars, making a communication between adjoining houses through the lines.

This was ordered to be made safe.

In the case of the new building on the north-west corner of Thirtieth Street and Eighth Avenue, the plans filed did not leave the space at the rear as required by law and were therefore disapproved, notwithstanding which the owner, F. Donnelly, proceeded to put his building up. The inspector found and reported the violation and notice thereof was served. The owner seemed to think it was only a matter of form and did not pay any attention to the notice, until it was referred to the attorney of the board, and he was arrested. He is now taking down the rear and altering the building so as to have it four feet shorter than before and otherwise remodeling the inside to conform thereto. Evidently it would have saved him time and expense to have heeded the warning of the chief inspector.

E. G. LOVE, Ph.D., Gas Examiner.

THE Philadelphia Company of Pittsburg makes the following statement showing the number of boilers and furnaces using natural-gas in October, 1866, and October, 1887:

	1866.	1887.
Boilers.....	803	1,164
Puddling furnaces.....	551	492
Large heating furnaces.....	439	517
Dwelling houses.....	4,000	9,000
Cubic feet of gas used in one day in the city.....	250,000,000	375,000,000
Present capacity of wells.....		1,200,000,000

Correspondence.

All correspondents should send us their names and addresses, not necessarily for publication, but as a guarantee of good faith and because it is often necessary to communicate with them for additional information before printing their communications. Anonymous letters will not be noticed.

A HOUSE FILTER WANTED.

NORTH CAROLINA BOARD OF HEALTH,
RALEIGH, N. C., October 22, 1887.

SIR: Will you kindly inform me of some inexpensive forms of house filters at present in the market which are efficient and easily kept in order?

Yours truly, ARTHUR WINSLOW.

[Referred to our readers.]

NOISE IN THE KITCHEN BOILER.

SIR: As a subscriber of your paper I take the liberty to ask you a few questions in regard to a boiler which makes an awful noise. The pressure it receives is from 70 to 80 pounds. The boiler is a copper one. I am positive it is not the pressure or the make of the boiler, and I therefore give you a sketch. Thanking you for an early reply, I remain one of your anxious readers, E. S.

[We are of the opinion your water-back is too large for the amount of water drawn from the boiler. Place a fire-brick in front of the water-back and try what it will do for you. If a whole brick proves too much use a part of one. If that remedies the evil use a smaller water-back hereafter.]

DEPTH OF ARTESIAN WELLS.

SIR: A few days since a discussion took place at a prominent New York City club between the owner, architect, and contractors of an extensive bathing establishment now in the course of construction in this city, upon the subject of artesian wells, one being now sunk for the bathing establishment referred to, of which Mr. Thomas A. Poole is the architect.

It was claimed that the deepest artesian well in this country had been sunk by Messrs. Belding Bros. & Co., silk manufacturers, of Northampton, Mass. Will you please oblige us by stating whether this is so and also by giving any further information on the subject that you conveniently can? Respectfully, B.

[In answer to the above query we give the following extract from a letter received from Messrs. Belding Bros. & Co., dated October 15, 1887:

"The deepest artesian well we have sunk is at Northampton, Mass., 3,700 feet. The next deepest well in America is at St. Louis, Mo., 3,180 feet, which furnishes a large supply of sulphur water.

"The deepest well in the world is in Prussia, a Government work, and something over 4,000 feet deep and furnishing hot water.

"The bore in our well is 8-inch and we worked 2½ years on it. We struck the rock at 150 feet (a sedimentary sandstone) and never got through it and got no water, although at Holyoke, Mass., 9 miles south of us, they get unlimited supplies of good water at 600 feet."

It may be of interest to add that a well was sunk 3,235 feet to supply the county buildings of St. Louis County, Miss., but without success. The largest well in the world is believed to be that at Passy, near Paris. It is two feet in diameter, 1,913 feet deep and delivers 3,795,000 gallons per day. The most celebrated is at Grenelle, a suburb of Paris, with a depth of 1,802 feet and a delivery of 880,000 gallons per day, with a force sufficient to raise it 120 feet above the surface. Wells 1,500 and 1,800 feet deep are said to exist in the province of On Tong Kiao in China.]

NEW JERSEY SANITARY ASSOCIATION.

THE thirteenth annual meeting of the association will be held at Trenton Friday and Saturday, October 28 and 29.

The following is the order of business:

FRIDAY, OCTOBER 28.

Meeting called to order at 10:30 A. M. Report and announcements by the Secretary. Paper on "The Prevention of the Spread of Contagious Diseases through the Schools," by J. Y. Simpson, M. D., of Orange. Discussion opened by T. W. Harvey, M. D., of Orange. Paper on "The Legal Aspects of the Question of the Pollution of Streams," by E. S. Atwater, Counselor-at-Law, of Elizabeth. Discussion opened by W. H. Lanning, Esq., of Trenton. Report of the Treasurer and Miscellaneous Business.

Afternoon Session, from 2 to 5 o'clock.

"Methods of Sewage Disposal in New Jersey," as described by those who have put the systems in operation—viz.: J. J. R. Croes, C. E., of New York City; C. Phillips Bassett, C. E., of Newark; George P. Olcott, C. E.,

of Orange, and others. Discussion opened by James Owen, C. E., of Newark; J. W. Pinkham, M. D., of Montclair. Paper on "Neglected Drainage Areas in New Jersey, and what should be done to improve them," by Professor George H. Cook, Ph. D., of New Brunswick. Discussion opened by L. B. Ward, C. E., of Jersey City; Professor A. R. Leeds, Ph. D., of Hoboken.

Evening Session, at 7:30 o'clock.

Prayer. Annual Address by the President, William K. Newton, M. D., of Paterson. Subject, "Sanitation Militant." Addresses on the sanitary bearings of the following educational topics: 1. The Length of School Days and Terms; 2. Recesses; 3. Competition; 4. Industrial Education; by Hon. E. O. Chapman, State Superintendent of Schools; Prof. Nicholas Murray Butler, President Industrial Educational Association; Prof. James M. Green, of Long Branch; Prof. C. E. Meleney, of Paterson; Prof. Charles Jacobus, of New Brunswick; Prof. Wright Eckersley, of Long Branch.

SATURDAY, OCTOBER 29.

Morning Session, from 9 to 12:45 o'clock.

Paper on "Poisons in Foods of Animal Origin," by Shippen Wallace, Ph. D., of Burlington. Discussion opened by Prof. F. A. Wilber, of New Brunswick; Dr. William K. Newton, of Paterson. Paper on "The Tenement-House Problem in Cities," by James C. Bayles, M. E., President of the New York City Board of Health. Discussion opened by D. Benjamin, M. D., of Camden. Paper on "House Sanitation," by Henry Mitchell, M. D., of Asbury Park. Discussion opened by Rev. A. E. Ballard, of Ocean Grove.

Afternoon Session, from 2 to 4:30 o'clock.

Election of officers. Paper on "The Collection and Disposal of Garbage," by E. L. B. Godfrey, M. D., of Camden. Discussion opened by Prof. H. B. Cornwall, of Princeton. Paper on "Vital Statistics," by E. M. Hunt, M. D., Secretary State Board of Health. Discussion opened by D. L. Wallace, M. D., of Newark; J. C. Pumpelly, Esq., of Morristown. Miscellaneous Business and adjournment.

The officers are: President, W. K. Newton, M. D., Paterson; First Vice-President, E. L. B. Godfrey, M. D., Camden; Second Vice-President, Henry Mitchell, M. D., Asbury Park; Recording Secretary, D. C. English, M. D., New Brunswick; Corresponding Secretary, Prof. J. Madison Watson, Elizabeth; Treasurer, J. C. Pumpelly, Morristown.

The Local Committee of Arrangements consists of W. W. L. Phillips, M. D., C. T. Ridgway, Esq., E. M. Hunt, M. D.

AN ADVANCE IN WROUGHT-IRON PIPE.

AT a well attended meeting of the Wrought-Iron Pipe Manufacturers of the United States, held on October 26 at the Fifth Avenue Hotel, New York City, it was unanimously decided to raise the prevailing card rate 2½ per cent. on all sizes of pipe.

Within the past five years this branch of the iron industry of the United States has more than doubled. The discovery of new natural gas and petroleum fields and the determination of telegraph, telephone, and electric-light companies to do away with overhead wires are creating a great demand for wrought-iron pipe, and the development of the great petroleum fields in Russia is adding to the demand for pipe all the time.

Novelties.

Under this heading we propose to describe and illustrate appliances of probable interest to our several classes of readers. The selection will be made without reference to the wishes of agents or patentees, being governed solely by considerations of novelty, ingenuity, and probable interest to readers, and especially the fact that they have not been elsewhere described. As a rule we shall make no comments, and it is to be distinctly understood that a notice does not imply approval. No charge will be made for these notices, and any offer of pay for their insertion will insure their omission. We shall be glad to have our attention called to novelties suitable for this section.

WATER REGULATOR AND ACCUMULATOR FOR HOUSE PURPOSES.

THE accompanying cuts show a novel contrivance for the purpose of utilizing the power which produces a water-ram or concussion in the pipes, to raise water to a higher level than the natural pressure of the works would send. In other words, a Brooklyn inventor has taken out a patent for a device in which he proposes to utilize the water-hammer in the plumbing pipes of a house to drive water into a storage tank. The greater the nuisance to the householder from the water-hammer due to defective plumbing the more water will be accumulated in the tank. If you want to get water into the tank it is only necessary to keep opening and shutting the faucet down stairs, and by-and-by you will get your tank full if you have patience and determination.

The figure represents the whole system on the second floor of a dwelling showing the mode of connecting the water-

pipes with the water-closet cistern W, directly over the main supply line B, and wash-basin, in an adjoining room. The closing of a faucet suddenly forces water through

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ENGINEERS' CLUB OF PHILADELPHIA.

A REGULAR meeting of the Engineers' Club was held October 1, 1887.

Past-President Washington Jones in the air; 30 members and 4 visitors present. Mr. J. M. Cameron, introduced by Mr. Henry G. Morris, described the Carnell air-ector.

This machine is intended to supply air to the furnaces of steam-boilers of all classes. Steam is taken from top of boiler and carried through the combustion-chamber, where it is heated to about 900° Fah., then to a distributing-apparatus discharging under the grate. The steam, heated to the condition of a gas, takes with it the necessary air for combustion. It is claimed that the heat to which the steam is raised, in connection with a reduction of pressure to 20 pounds per square inch, increases the relative volume to 1,800, which would be eight times more effective than saturated steam. The heat taken from combustion-chamber is given out to the air entering the furnace. Tests are said to have shown an increased boiler-power of 28 to 100 per cent., with a proportionate saving in fuel of two per cent. above that obtained by natural draught.

Mr. Henry G. Morris exhibited and described a working model of a traveler to carry wires, ropes, etc., through conduits, which he had devised.

The apparatus consists of two parts, one placed ahead of the other, and each provided with spring claws which will slide ahead in the conduit, but will take hold of the sides and prevent any backward motion. The parts are operated by two cords working on a system of pulleys, so that, by the alternate pulling of the cords, the whole apparatus will move ahead of the operator through the conduit. That is to say, pulling one cord will drag the rear piece up to the front piece, and pulling the other cord will send the front piece a distance ahead, each part, with the attached pulleys, holding firmly to the sides while the other part is being moved.

Prof. L. M. Haupt made some remarks upon his "Experiments with Current Deflectors at Five-Mile Bar," and showed how urgently the city and river interests required a channel across it. He then suggested a plan whereby he proposed to create a channel, sufficient to meet the demands of commerce.

The Secretary, Mr. Howard Murphy, announced the death, since the summer adjournment, of Mr. Frank Maddock, active member of the club.

ENGINEERS' CLUB OF KANSAS CITY.

A REGULAR meeting of the Engineers' Club of Kansas City was held at the Deardorff Building, October 3, 1887, J. A. L. Waddell, Vice-President, presiding; T. F. Wynne, Secretary, pro tem.

Upon a canvass of ballots, E. W. Stern, Charles H. Talmage, and Charles W. Hastings were elected members.

The paper of the evening on "The Construction and Operation of the Ninth Street Cable Railway," prepared by Mr. M. K. Bowen, was read by Mr. C. G. Wade.

Mr. P. W. Keersted was proposed for membership by G. W. Pearson and J. A. L. Waddell.

Mr. Keersted was invited and consented to read a paper at the next meeting, subject to be announced.

PLUMBING JOBBERS' CLAM-BAKE.

THE New England Association of Jobbers of Plumbers' Supplies are to have a "genuine Rhode Island clam-bake" at the Club House, Providence River, on Friday, November 11, next. Guests will assemble at Narragansett Hotel, Providence, at 10 A. M. on that day.

ARCHITECTURAL COMPETITIONS.

FORT WAYNE, IND.—The Committee (Messrs. Dockman, Woulfe, Read and Michell) will advertise at once for plans for the new city hall.

LOS ANGELES, CAL.—The President of the St. Vincent Hotel Company, Major E. W. Jones, will advertise at once for proposals for plans, etc., for building a \$400,000 hotel.

For works for which proposals are requested see also the "Proposal Column," pages 601-604-608.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE ENGINEERING & BUILDING RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

WATER. SEWERAGE. ETC.

LOS ANGELES, CAL.—The Mayor will appoint at once three local engineers to pass upon the sewerage plans.

BRIDGEPORT, CONN.—The Board of Public Works will advertise at once for the construction of sewers.

SAVANNAH, GEO.—A movement is started to obtain a complete system of sewerage (small pipes and flush-tanks).

MILWAUKEE.—Water-mains will be laid in 24th Street, from Galena to Walnut Street, one block, and from 23d Street to 24th Street, and Walnut Street. Valentine Blatz is erecting well-boring machinery on Johnson Street for the purpose of deepening the artesian well at Blatz's Brewery.

WEST STRATFORD, CONN.—There is talk of erecting water-works on Success Hill to supply the borough of West Stratford and the town of Stratford.

ELYRIA, O., must have larger water-supply.

COSHOCTON, O., voted October 24 to build water-works.

JACKSONVILLE, ILL.—Address the City Clerk at once in regard to plans for better water-supply. City Council has the matter under discussion.

POTWIN, KAN., is to have a sewerage system costing \$12,000. For further particulars address John T. Clark.

FRANKLIN, MASS.—The stand-pipe of the water-works burst on October 26; loss, \$8,000 to \$12,000.

CHARLESTON, S. C.—The Water Committee has reported that a new reservoir should be built at a cost of \$12,000, and a new 1,000,000-gallon pumping-engine be bought to increase the water-supply. Council has adopted the report. Address the City Clerk or W. B. Lawrence, of Water Committee of City Council.

WEST ORANGE, N. J.—Our correspondent writes: "There have been no steps taken to establish water-works in the township of West Orange—nothing more than a communication from D. N. Roper, offering an opportunity to the town authorities to avail themselves of one."

REDDING, CAL.—Parties are surveying a ditch from Spring Creek, six miles north of Redding. The work is reported to be for another water company for the city.

MARBLEHEAD, MASS.—At a town meeting held October 18, at Marblehead, it was voted to issue bonds to the amount of \$42,000 for water-works. It was also voted that the water commissioners be authorized to have a survey of the whole town made, and that the commissioners report at an early day an estimate of the cost of construction.

WATER COMPANIES.—Incorporated in Pennsylvania are the Loyalhanna Water Company of Westmoreland County, and the Salem Water Company.

DULUTH, MINN.—Surveyors commenced work on the dikes of the St. Louis River to locate the sites of 10 dams for the St. Louis River Water Power Company, of which Jay Cooke and New York, Philadelphia, Chicago, Milwaukee, Minneapolis and St. Paul capitalists are large stockholders.

CEDAR RAPIDS, IOWA, Water Company will bore an artesian well near the works. The contract has been let to the Miller Artesian Well Company, of Chicago. The contract calls for a well 2,500 feet deep, if it is found necessary to go that far to secure a supply of water.

MAYSVILLE, KY.—Our correspondent writes: "This company does not intend to make additions to pipe lines and machinery before spring."

GEORGETOWN, KY.—The construction of water-works is actively discussed here. Address the City Clerk.

ALTOONA, PA.—Address C. W. Knight, Consulting Engineer, on pumping machinery, etc., needed for extending the water-supply, which Mr. Knight is now planning. President Kilgore, of Common Council, may also be addressed.

ST. LOUIS, MO.—It is proposed to erect a pumping-station at the Chain of Rocks. Address Mayor Francis.

JERSEY CITY, N. J.—The Green Gauge-Tube Well Company want to get a chance to supply the city with water, in case the present plant is abandoned. Clerk Finck, of the Board of Works, has been directed to notify them to present a proposition.

BUNKER HILL, ILL.—Our correspondent writes: "The proposition to establish water-works is only discussed and nothing tangible arrived at. It is a question to be looked into by the Citizens' League. There is no immediate prospects that they will be established."

HELENA, MONT.—Our correspondent writes: "The Helena Water Company, a corporation having a franchise from the City of Helena, has sunk a well and is building pumping-works and a reservoir, and laying 15 miles of pipes for a system of water-supply. George F. Woolston, manager. The city is about to enter upon the construction of a system of sewerage to cost \$150,000. Plans are not yet matured."

VALLEY FALLS, KAN.—The following bid for constructing water-works was received by H. D. Butts, City Clerk, October 15: U. S. Wind Engine and Pump Co., Batavia, Ill., \$14,778, and the contract was let to them.

TORONTO, ONT.—The scheme for new water-pipe, new pumping-engines, etc., to which we have previously referred, has been endorsed by City Council. Address Alderman Boustead.

SYRACUSE, N. Y.—The Syracuse and Salmon River Water Company has applied to the City Council for a franchise. Mr. W. A. Sweet is president.

NEWPORT, R. I.—Next month the taxpayers will vote upon the expenditure of \$100,000 for the completion of the sewer system. The city invited three gentlemen to inspect the trunk sewer and outlet and make a report—viz.: George E. Warren, Professor Fairman Rogers, of Philadelphia, and Mr. Charles E. Hammett.

AUSTIN, TEXAS.—Our correspondent writes in reference to the Sylvester Watts Water Company: "Right of way was refused the Sylvester Watts Company by our City Council, and they are not doing any construction of water-works in this city. We have one water company which has been in operation some ten years."

GRAND RAPIDS, MICH.—The Board of Public Works on October 19 had up for discussion plans and estimates for supplying the city with water prepared by J. D. Cook, C. E., of Toledo. Work will be done.

MONTROSE, CAL.—Our correspondent writes: "Franchise granted to C. E. McConnell, et al., to construct water-works, but don't think there will be anything done in the matter for two years anyhow."

WEST DE PERE, WIS.—Our correspondent writes in regard to water-works: "The matter is a private enterprise, as at present talked of, and not a city matter. There will probably be an artesian well put in by private parties, and the city will probably take some steps to get a supply of water from it when furnished. J. P. Willard, of this city, is interested."

SOUTH EVANSTON, ILL.—The matter of a contract with G. C. Morgan for supplying water seems not to be settled yet. The source is to be driven wells.

POMONA, CAL.—Address P. C. Towner about his project for piping water from the Cy Burdick property to the city.

HERKIMER, N. Y., is experimenting with the sinking of wells for a water-supply.

CLAYTON, N. Y.—Our correspondent writes: "There have been no steps taken as yet to establish water-works here. Last season there was some kind of talk about putting in the Holly system, but the town bought a Silsby fire-engine as a protection in a case of fire, and I think it doubtful if the town would take any action on water-works for the present."

SPRINGFIELD, ILL.—Our correspondent writes: "Our Commissioners have as yet not decided whether to put in water galleries or tube wells. The water is very low. The project should be pushed with dispatch at once."

LAKE, ILL.—After much discussion the contract for furnishing a pumping-engine has been awarded to the Holly Manufacturing Company, of Lockport, N. Y.

SANTA ROSA, CAL.—Our correspondent writes in reference to water-works on Mark West Creek: "At an adjourned meeting of the Common Council of the city of Santa Rosa, the petition of J. B. Davis and his associates for a franchise to lay water-pipes and to carry water into the city from Mark West Creek was granted and a committee, of which the Hon. A. P. Overton, Mayor, is chairman, appointed to draw up a proper ordinance. There is no doubt but what the new water works will be a success and completed within a short period."

BARRE, ONT., has voted against the introduction of water-works.

MILWAUKEE.—An additional sum of \$60,000 has been appropriated by the Council for the purpose of constructing the 12-foot flushing tunnel from Lake Michigan to the Milwaukee River. It will be 2,500 feet long and will have a mean fall of 12 inches. It will be 75 to 85 feet below the surface of Dane Place. The engines and boilers will be located on the lake shore and have a capacity of 350 millions of gallons daily. It was decided to recommend to the council a resolution instructing the Board of Public Works to advertise for bids upon and to award contracts for the construction of the tunnel.

JAMESTOWN, N. Y.—The Jamestown Water-Supply Company has bought the Southland Farm, and will begin at once the erection of a pumping plant and laying water-mains.

GREENBUSH, N. Y.—On October 24 the Sewer Commissioners awarded the contract for the first section of the sewer system to McGowan & Van Vranken, of Schenectady.

ST. JOHNLAND, L. I.—We recently noted that plans were to be prepared for the Charities Commissioners for water and sewerage works, roadmaking, and other improvements at the St. Johnland County Farm. Chief Engineer Carey has now presented the plans and specifications. They call for a reservoir, pumping engine, much cast-iron and stoneware pipe, valves, hydrants, etc., considerable excavation and masonry work and sewer construction, both brick and pipe. The cost is estimated at \$350,000. The Board of Supervisors of Queens County have the estimate under consideration.

WIARTON, ONT.—Water-works will be built here. Address, until November 1, T. D. Galloway, Clerk of the Municipality.

WATER-WORKS.—Proposals will be received for a system of water-works for Winchendon, Mass. The Fire Commissioners and a committee of citizens have been authorized to obtain plans for the construction of works for fire and domestic purposes. The water will be supplied from artesian or driven wells, or from Naukeag Lake in Ashburnham. Council has appropriated \$500 for Survey. Address the Water-Works Committee.

ELLENVILLE, N. Y.—The Board of Trustees on October 19 voted to authorize the issue of \$16,000 of bonds for increasing the water-supply.

GAS AND ELECTRIC-LIGHTING.

EAST SAGINAW, MICH.—The Hartford Electric-Light Company is organized.

INCORPORATED in Ohio is the Holmes County Gas and Oil Co.; capital stock, \$9,000.

ST. CLOUD, MINN.—J. H. Woolsey, of the United States Electric-Light Company, of St. Paul, will erect a light plant here.

PLAINFIELD, MASS.—Plainfield is to have incandescent electric-lights.

BALTIMORE, MD.—Mayor Hodges has vetoed the ordinance making a five-years' contract with the American Electric-Light Company.

KNOXVILLE, TENN.—City Council has directed the Mayor to annul the contract with the Knoxville Gas Company and obtain electric street-lamps.

SANDUSKY, O.—Under a contract made with the gas company October 10, all the gas-posts in the city will be displaced by electric-lamps.

LAREDO, TEX.—City Council has propositions before it looking to lighting the streets with electricity.

INDIANAPOLIS, IND.—The Indianapolis Natural-Gas Company has contracted with Pittsburg parties to furnish twenty miles of pipe and fittings for the gas lines. A. M. Fletcher is a director.

EAST ST. LOUIS, ILL.—Incorporated is the Pike Electric Company, of East St. Louis; capital stock, \$25,000. Messrs. Edward W. Pike, N. Oscar Gray, and Sherman B. Pike, incorporators.

HYDE PARK, MASS.—The town has contracted with the American Electric Manufacturing Company to furnish double arc-lights of 2,000-candle-power each, at an annual cost of \$70 per light, for a term of three years. Any additional lights must be furnished at the same price, and under same conditions.

EDWARDVILLE, ILL.—has made a five-years' contract for electric street-lighting.

GLENS FALLS, N. Y.—is discussing lighting the streets by electricity.

JERSEY CITY, N. J.—The Police Board, October 19, decided to renew last year's contracts with the companies holding them for gas, electric and oil lights. The contract with the Jersey City Electric-Light Company is to be for forty or more lights at the rate of 40 cents per night.

WASHINGTON, D. C.—The Westinghouse Electric Company has received notice that it has been awarded the contract for lighting the Senate Chamber of the Capitol at Washington. This contract calls for 1,300 electric-lights, which will include all candle-power from 9 to 16, 25, 50, 75, 100, 150. The entire plant will be placed in the building, including the power, machinery, and other essentials.

WASHINGTON, KAN.—Incorporated is the Washington Electric-Light and Power Co.; A. W. Moona, and others.

BATTLE CREEK, MICH.—Incorporated is the Battle Creek Electric-Light and Power Co.; W. A. Foot, and others.

RICHFIELD SPRINGS, N. Y.—will have electric street-lights. Address Dr. N. Getman.

LOWVILLE, N. Y.—The Village Board has granted John D. Moore privilege to erect poles and wires for electric-lighting. The lamps are of the American Electric-Light Manufacturing Company.

ALLENTOWN, PA.—has signed a contract with the Allentown Electric-Light and Power Company to light the streets with electric-lamps.

LIMA, O.—Address the Lima National Gas-Company about street-mains, etc., for their plant.

HURON, DAK.—is to have electric-lights.

CHATHAM, ONT.—wants to obtain an electric-light plant for her streets.

SAULT STE. MARIE, MICH.—has granted a thirty years' franchise to a natural-gas company to sink wells and lay mains.

ORANGE, N. J.—has at last granted a franchise to the Edison Illuminating Company to erect poles and wires for lighting.

NEWTON, KAN.—Wells will be sunk for natural gas.

WEST MIDDLETOWN, PA.—Incorporated is the Citizens' Light and Heat Company, of West Middletown.

BELVIDERE, N. J.—The Belvidere Gas and Electric-Light Company has purchased the entire plant, machinery and poles necessary for lighting the town by electricity.

STEAM-HEATING, BUILDINGS, ETC.

MONTREAL, CAN.—Dows & Son, of Ottawa, have the contract for the depot of the Canadian Pacific Railway.

SEWARD COUNTY, NEB.—will vote November 8 on raising \$75,000 for a court-house.

CINCINNATI, O.—Proposals will be received until November 19, at the office of W. B. Smith, for the erection of an armory; Hannaford & Sons, architects.

POTTSTOWN, PA.—Neff Bros. are establishing a silk mill plant under the title, Pottstown Silk Mill Association. The building will be brick, 3 stories high, with engines, electric-light dynamo, and shafting. There will be steam-heating apparatus also. Time for bidding is extended to October 29. Address G. F. Malsburger, Pottstown, Pa.

PHILADELPHIA.—The Pencoyd Iron and Steel Works are building a 200x200 foot brick and iron bridge shop and will put in new battery of boilers, compressors, accumulators, and hydraulic and forging plant.

POTTSTOWN, PA.—The contract for steam-heating the Security and Trust Company's new building is to be let. Address Edwin Bartollett, architect, Phoenixville, Pa.

WHITESTONE, L. I.—A machine works will be built here. W. D. Bishop, of Bridgeport, Conn., is Manager; capital, \$2,000,000.

WILKESBARRE, PA.—Organized is the Nanticoke Steam Heat, Power and Water Company. Work upon the plant will be begun at once, and upon the trenches for the pipes in a very few days. President, Sol. Hirsch; Vice-President, Henry Connell; Treasurer, J. C. Brader; Secretary, Lawyer Fritz.

KALAMAZOO, MICH.—The Supervisors will hold an election on the question of raising funds for a new county almshouse.

ROME, N. Y.—See our Proposals for reference to heating apparatus, etc., for the Central New York Institution for Deaf Mutes.

PORTLAND, ME.—Coffrod & Saylor, of Philadelphia, have contracted with the Union Station Company to build the iron train sheds here. The contracting price is said to be between \$75,000 and \$80,000. Mr. M. W. Wisler has charge of the work.

BRIDGES.

ST. LOUIS, MO.—On November 15 the Board of Public Improvements will award contracts for iron superstructure of the Grand Avenue Bridge.

BRIDGES.—See our Proposals for reference to bridges at St. Louis, Mo.

BEVERLY, MASS.—Thomas D. Lovett is at work upon plans for a proposed bridge over the railroad to Bridge Street, Rial Side.

BRIDGE.—A contract has been let to the San Francisco Bridge Company for \$32,801 to build a bridge across the Mojave River between Daggett and Calico, Cal.

TRENTON, N. J.—The contract for building the bridge over Miry Run, near Newtown, was awarded October 22 by the Board of Freeholders. Austin Walton secured the mason work for \$1,400, and the New Jersey Steel and Iron Company will do the iron work for \$850.

LEAVENWORTH, KAN.—Our correspondent writes: "I understand arrangements are being made for the construction of a bridge across the Missouri River opposite this city. A company has been organized and a charter obtained for such purpose."

EAU CLAIRE, WIS.—The municipal election October 18 on the proposed issue of \$25,000 bridge bonds resulted in favor of the issue of bonds.

DUBLIN, GEO.—Our correspondent writes: "No steps have been taken whatever by the town or county for a bridge. There has been some talk of submitting the question of building a bridge by issuing bonds by the the county and town to a vote of the people of the county and town."

NEWARK, N. J.—Our correspondent writes in regard to the proposed bridge over the Passaic to Kearney: "The only action taken so far, October 24, has been the appointment of a joint committee of Essex and Hudson Counties to consider the subject."

KANSAS CITY, MO.—The contract for a bridge at Montgall Avenue, this city, has been awarded to the Kansas City Bridge and Iron Company.

SACRAMENTO, CAL.—The Board of Supervisors October 19 opened bids for the construction of a new bridge across the American River at Twelfth Street. The bids were as follows: McKinnon & Tumelty, Stockton, \$36,700 and \$37,500; B. McMahon & Co., San Francisco, \$33,750; San Francisco Bridge Company, \$29,977; King Iron Bridge Company, of Cleveland, O., \$29,994, \$32,795, and \$44,895; American Bridge and Building Company, \$29,675, \$32,650, and \$48,600; Pacific Bridge Company, \$37,281; California Bridge Company, \$43,786, \$34,697, \$29,970, \$24,875. The bids were referred to the Committee on Contracts.

MARINETTE, WIS.—will build a \$60,000 bridge over the Menominee.

ZANESVILLE, O.—The County Commissioners will build a bridge over Muskingum River.

LEWISVILLE, O.—The County Commissioners will build a bridge here.

TOWSONTON, MD.—A bridge will be built here.

WACO, TEX.—Proposals will be received for an iron bridge over the Brazos River. Address, until November 14, the Commissioners' Court, Waco, Tex.

WATERTOWN, N. Y.—The King Iron Bridge Company, of Cleveland, O., and the Wrought-Iron Bridge Company, of Canton, O., have been awarded the city contracts for constructing bridges across the north and south branches of Black River, at \$10,000 and \$3,350 respectively.

WESTFIELD, MASS.—The County Commissioners have adopted plans for crossings of the N. H. & H. R. R. at this place.

DEFIANCE, O.—See our Proposals in regard to bridges in Defiance Co., O.

BELLOWS FALLS, VT.—The Cheshire Railway will build a bridge here. R. Stewart, General Manager, at Keene, N. H., may be addressed.

HOLLISTER, CAL.—The Commissioners will build a \$15,000 bridge over the San Benito River.

ASHTABULA, O.—The County Commissioners will build a \$30,000 bridge.

SIoux CITY, IA.—The contract for building the trestle work and stone abutments of the east approach of the Missouri River has been let to Wakefield & Hill, of this city.

WASHINGTON, MO.—A bridge will be built over the Meramee River at Short's Ford. The contract for abutments has been awarded to Ira Rean at \$5,000.

APPONAUG, R. I.—The award of contract for an iron bridge at Crompton has been postponed until November 7. Address the Town Clerk of Apponaug.

MILWAUKEE.—The Milwaukee Bridge and Iron Co. has been awarded the contract for the Belle Isle bridge at Detroit for \$295,000.

CHATTANOOGA, TENN.—Still another company desires a charter to build a bridge across the Tennessee River.

COLUMBUS, NEB.—An election was held in this city October 17 to vote \$30,000 in bonds to build a permanent bridge across the Loup Fork. The bonds were carried, 348 voting for them and 6 against.

SAN DOMINGO.—Constable Bros., engineers of New York, have furnished plans for a wrought-iron drawbridge for San Domingo.

BIRMINGHAM, ALA.—The Birmingham Bridge and Bolt Works Company has been incorporated at Birmingham, Ala., with a capital stock of \$100,000.

BROOKLYN BRIDGE.—Bids for iron and steelwork of approach: The New Jersey Steel and Iron Works, 5.57 cents per pound erected; Keystone Bridge Company, 7.34 cents per pound erected. The contract was awarded to the New Jersey Steel and Iron Works. The Dickinson Manufacturing Company, of Scranton, Pa., has the contract for two switching-engines, to weigh 44,000 pounds, and to cost \$5,500 each.

STREET WORK AND PAVING.

LITTLE ROCK, ARK.—The paving of Main Street will be pushed. Address Fred Rickon, City Engineer.

SAVANNAH, GEO.—Address the Council Committee on Streets in regard to much paving and other work now to be done.

DAVIS AVENUE, WEST CLEVELAND.—will be paved, etc. Address the Clerk, A. P. Fairbank, 18 Wade Building, Cleveland, O.

ST. LOUIS, MO.—The Board of Public Improvements will award contracts November 7 for wood and granite paving.

TORONTO, ONT.—Plans are being prepared for the Esplanade improvement.

ST. LOUIS, MO.—On November 21 contracts will be let by the Board of Public Improvement for much grading and paving. Address Henry Flad.

JERSEY CITY, N. J.—Ogden Avenue will be improved, sewered, etc.

PITTSBURG, PA.—Address E. M. Bigelow, City Engineer, about improvements of Carson Street, and sewers in various streets and alleys.

ARENAC, MICH.—A new State road is to be constructed in Arenac County, between the towns of Arenac, Au Gres, Mason, and Turner. It will be over ten miles long.

COLUMBUS, O.—A great deal of street-work is projected here, as the following estimate of the City Engineer, recently made, shows: Grading and constructing a stone block pavement and setting 5-inch curb on Long Street, \$234,722.50; Medina stone for above, \$226,675; street-railway's portion, \$61,500; grading and constructing a Hayden block or fire-clay brick pavement on Mount Street, \$11,070; West Virginia fire-clay brick for above, \$10,025. Medina or granite curb in place of Berea curb would cost about \$1,450 more.

SAN DIEGO, CAL.—The only bid presented October 13 to the City Trustees for paving certain streets was withdrawn, and the work will be readvertised. The estimated cost is more than \$500,000.

LEAVENWORTH, KAN.—Address City Engineer G. T. Nelles in regard to paving Third Street.

WORCESTER, MASS.—Address the City Engineer in regard to extensive paving and other improvements to be made to the streets.

RAILROADS, CANALS, ETC.

HOWESVILLE, KY.—The Howesville and Pellville Mineral Railroad Company was organized October 24 with General D. L. Adair as the presiding officer. It is proposed to build a road from this place to Pellville.

NEVADA CITY, CAL.—The Board of Supervisors has granted a franchise for an electric railway from Nevada City to Grass Valley to the Directors of the Nevada County Land and Improvement Association.

NAPA, CAL.—A contract has been let to J. T. Davis to grade twenty miles of the Napa, Lake and Humboldt Railroad between Conn and Bull's canyons. The work will be pushed.

KNOXVILLE, TENN.—Chief Engineer Ramsner, of the Carolina, Knoxville and Western Railroad, is prosecuting surveys from Nashville to Emory Gap.

SAN DIEGO, CAL.—Address H. L. Storey, of the San Diego Street Car Company, in regard to several projected lines, electric and horse.

ELIZABETH, N. J.—City Council has granted a franchise to the Elizabeth Street Railway Company to build an electric motor line.

DENVER, COL.—The Denver and West Side Cable Railway Company has filed articles of incorporation. George Wirt Bowman, Thomas J. Burke, and John D. Woodruff are incorporators and directors. The objects of the company are to operate a railway with steam or other power through Denver, Highlands, and Barnum.

HILLSBORO, ILL.—The Springfield and Southern Railway has received right of way through this county. Chief Engineer Davies has completed the work of preparing the profiles taken from the recent survey, and he is now ready to make a report as to estimates and details for constructing the road.

LITTLE ROCK, ARK.—The Street Railway Company will make considerable extensions. Address R. W. Worthen.

MOLINE, ILL.—A survey made under the auspices of the Moline Business Association, was completed October 25, for a lateral canal around the upper rapids of the Mississippi, beginning at the head of the rapids just about Rapids City and running through Rapids City, Hampton, and Watertown to Moline, where it would strike the Government water-power pool, a lock at the lower end of which would secure entrance to the main branch of the river at Rock Island.

BIDS OPENED.

CHAUTAUQUA LAKE, N. Y.—The contract for dredging the outlet of Chautauqua Lake has been let to Willard Johnson, Fulton, N. Y., at 21½ cents per cubic yard.

KALAMAZOO, MICH.—On October 24 bids for the construction of the proposed new water-works, well, and appurtenances were considered by City Council. They were as follows: Jaynes & Son, of Detroit, \$8,790; George C. Winslow, Kalamazoo, \$8,300; W. R. Coats, Kalamazoo, \$6,500. The committee recommended that the bid of W. R. Coats be accepted and the contract was awarded to him.

ALBANY, N. Y.—Contracts for improvements at Armory Hall have been awarded to T. E. Kerwin, plumber; James Feeney, carpenter, and P. J. Sweeney, steam-fitter.

INDIANAPOLIS, IND.—The following bids for Medina stone pavement on Washington Street, 26,666 square perches, were received by S. H. Shearer, City Civil Engineer, October 17:—

Walter S. Biglow, Buffalo, N. Y., pavement per lineal foot front on each side, \$26.40; curb, no bid.

T. B. McNaughton, Buffalo, N. Y., \$24.25; 88c.

Claffen Paving Co., Cleveland, O., \$23.63; 85c.

William F. Shanks, Louisville, Ky., \$25.40; 85c.

BALTIMORE, MD.—Contract for furnishing the material and doing the work on a retaining wall on the Falls Road from Maryland Avenue to Boundary Avenue, was awarded to Tracy & Nardin at \$12,680.83. The other bids were: Wm. Gilmor, \$13,470.95; Holloway & Fox, \$14,679.58; Conway & Bates, \$12,887.64.

LOS ANGELES, CAL.—Bids for constructing the city hall were opened October 8, by the Building Committee, as below:—

For carpenter-work—F. E. Greene, \$128,600; W. R. Phelps, \$116,150; A. F. Mackey, \$116,000; W. O. Burr, \$109,100; Albert Washbourne, \$99,888, and Robert Smiley, \$98,779.

For brick-work—James W. Wadsworth, \$97,171.

Plumbing, gas-fitting, and sewers—W. C. Furrey, \$6,000; William Henderson, \$5,350, and H. Williamson, San Francisco, \$4,344.

It was decided that the city should readvertise for bids for the erection of the building, complete in every respect, including sidewalks and curbing, and also to advertise for bids for the brick-work and stone-work in one bid, and the remainder of the work in another bid.

HELENA, ARK.—The bids for the construction of 8 miles of levee of the Cotton Belt District No. 1 that were filed the 15th of the month were opened October 17. The bid of Messrs. J. S. McTighe & Co., of Memphis, was the lowest and the contract was awarded to them. They contract to do the work at 17 cents per cubic yard. They begin work on the 27th of this month and guarantee to have the work completed by January 15, 1888.

PHILADELPHIA.—Bids were opened at the Board of Health office for plumbing work ordered done by the board on the premises Nos. 2511 to 2529 Gordon Street, and the following were received: Lewis O. Howell, Jr., \$952; John A. Fagan, \$392; the latter was awarded contract. For plumbing work required at 3303 Woodward Avenue, the bidders were Deckson & Dover, \$175; Lewis O. Howell, Jr., \$116, and John M. Sullivan, \$138. There was but one bid received for the plumbing work for the Municipal Hospital, 21st Street and Lehigh Avenue, and the Health Officer was directed to readvertise.

SAN DIEGO, CAL.—Bids for constructing the sewerage system were opened as below by the City Trustees October 13:—

The Pacific Bridge Company offered to dig trenches, etc., for 89½ cents per lineal foot and to lay pipes for 9 cents additional.

Alexander McBean would dig trenches, lay pipe, cement and back fill for 97 cents per lineal foot. Flush tank on Sixteenth Street, near L, \$1,450. Flush gate in reservoir, \$4,900. He will furnish all material except iron, and build inspection holes for \$7.50 each.

M. McDonald, of San Bernardino, offered to do the work with the exception of furnishing pipe and iron, and the building of manholes and lampholes, for \$133,000.

George H. Chapman's bid was: 155,000 feet of sewer, with trenches, 90 cents; flush tank, \$6,600.

The American Bridge Company offered to do the sewer work for 89 cents, and to construct the flush tank for \$7,000.

The bids were referred to the Sewer Committee, City Engineer and Superintendent of Streets.

MILWAUKEE, WIS.—The Board of Public Works October 25 awarded the contract to construct the sewer on Twenty-first Street to F. J. Foran, at \$1.69 per foot; also to Dan O'Driscoll, the contract for the construction of the sewer on Mitchell Street, at \$3.80 per foot.

DULUTH, MINN.—Contract for grading Second Street has been awarded to McLennan & Hannah, at \$7,134.75.

Bids for various work have been received by the Board of Public Works, as follows: grading Twelfth Avenue, east, McLean & McKenzie, \$9,134.25; J. S. Wolf & Co., \$6,885.50; Heney & Derby, \$6,637.50.

Sewer in Alley, J. S. Wolf & Co., \$18,681.50.

Sewer in Third Street, J. S. Wolf & Co., \$3,452.

TOO LATE FOR CLASSIFICATION.

DERRY, PA.—Incorporated is the Salem Water Company, of Derry. P. N. Janeway, Edward Pitcairn, and others, incorporators.

SPARTANBURG, S. C.—The Spartansburg Water Company has been incorporated; capital stock, \$100,000. John F. Moffett, Henry C. Hodgkins, and others, incorporators.

GREEN BAY, WIS.—Our correspondent writes: "The city of Green Bay has taken no steps yet toward building an iron draw-bridge on Walnut Street bridge. The improvement is needed, and will, I think, be done during the coming winter; but before it is decided to do the work the matter will have to be submitted to a vote of the electors of the city."

PHILADELPHIA.—Messrs. I. H. Hathaway & Co., of 727 Walnut Street, this city, have been awarded the contract to build a bridge across the Wissahickon, at Springfield.

OAKLAND, CAL.—The contract for a bridge, costing \$45,000, to be built across the Umpqua River at Roseberg, has been awarded to the California Bridge Co., of this city.

SAN FRANCISCO, CAL.—The San Pedro Harbor, Dock and Land Company has been incorporated, with E. H. Pardee, Charles N. Fox, of Oakland, and others as a Board of Directors. The company propose to build a wharf and improve San Pedro Harbor.

SACRAMENTO, CAL.—The Board of Supervisors have awarded the contract for building a bridge over American River, mentioned elsewhere, to the California Bridge Company at \$34,697.

NEWPORT, KY.—It is reported that the contract to construct a bridge over the Ohio River here has been awarded to the Union Bridge Co., of New York, at \$1,500,000.

WATERVILLE, O.—The contract for the construction of a bridge over the Maumee River at this place has been awarded to Stephen Brosiguse.

EAU CLAIRE, WIS.—The city has voted for \$25,000 bridge bonds."

NEW ULM, MINN.—Bids are being received for the Brown County Court-House. Carl F. Struck, of Minneapolis, is the architect.

STILLWATER, MINN.—Main Street will be paved at a cost of \$14,763.

MINNEAPOLIS, MINN.—Bids have been opened for steam-heating in the Work-House extension, as follows: De Soto Boiler-Works, plant complete, \$2,335; J. M. Kelly & Co., boiler and connections, \$1,475; Porter Steam-Heating Co., plant complete, \$2,270; M. W. Glenn, boiler and connections, \$1,266; B. H. Shafer, boiler, \$1,000.

ST. PAUL, MINN.—Contracts awarded by the Board of Public Works: Grading Park Avenue and other streets, to William A. Davern, for \$15,250; grading Lafond Street, to William A. Davern, \$7,245; grading Delos Street, to McArthur Bros., \$3,000; grading Sibley Street, to James Forrestall, \$5,400; sewer on Iglehart Street from Louis to Farrington, to Patrick Doherty, \$1,367; sewer on Iglehart and Dale Streets, to Patrick Doherty, \$7,693.

The Board of Fire Commissioners has awarded contracts: Steam-heating plant, Central Fire Hall, \$1,950, to Thomas Davis; shops for repairs and storage to Rundle & King, \$2,500, and Commissioner Prendergast and Chief Black authorized to locate drive-wells and contract for cisterns, windmills and pumps for fire purposes at Merriam Park and Hamline.

PROPOSALS.

(Continued from page 608.)

OCTOBER 27, 1887.
SEALED PROPOSALS will be received at the Office of the Supervising Architect of the U. S. Treasury Department at Washington, D. C., and opened at 2 p. m. of the 30th day of November, 1887, for furnishing and putting in place complete the iron stairs, etc., of the Post-Office, etc., at Hannibal, Mo. Each proposal must be accompanied by a certified check for \$500, made payable to the order of the Treasurer of the United States. The right to reject any bids is reserved. The plans and specifications may be had and any information obtained by applying to this office or the office of the Superintendent, WILL. A. FRERET, Supervising Architect.

PROPOSALS.

TREASURY DEPARTMENT, U. S. Life-Saving Service, Washington, D. C., October 26, 1887. Sealed proposals will be received until 2 o'clock P. M. of Saturday, November 19, 1887, for the construction of a life-boat station at Galveston, near east end Galveston Island, Texas. Plans and specifications containing full information, and forms of proposals, can be obtained from the Superintendent of the Eighth Life-Saving District, Custom House, Galveston, Texas; Collector of Customs, New Orleans, La., Superintendent of Construction, Life-Saving Stations, No. 24 State Street, New York City, and upon application to this office. S. I. KIMBALL, General Superintendent. 23

CITY HALL.—Proposals will be received until November 4, for the construction of the superstructure of the City Hall Building in Omaha, Neb. Bids will be made on printed blanks furnished by the Board of Public Works, and to be accompanied with a certified check in the sum of \$1,000, as evidence of good faith. Address St. A. D. Balcombe, Chairman Board of Public Works, Omaha, Neb.

BRIDGES.—The Board of Commissioners of Defiance County, O., will receive proposals at the County Auditor's office, at Defiance, O., until November 22, for furnishing the necessary materials and building two bridges of iron, with two stone abutments each. The Clarksville across the St. Joe River in Milford Township, and the Arrowsmith bridge over Lost Creek in Farmer Township, Defiance County, O. Clarksville bridge to be of one span, 165 feet between masonry, and must have a roadway 18 feet wide in the clear, and to consist of one span; height of truss not less than 26 feet; capacity, 80 pounds per square foot of floor. Arrowsmith bridge to be of one span, 76 feet between masonry, and must have a roadway 16 feet wide in the clear; capacity, 80 pounds per square foot of floor. W. T. Hill, Auditor, Defiance, O.

PUMPING-ENGINES.—Proposals will be received at the City Engineer's Office, Minneapolis, Minn., until November 17, for two horizontal compound condensing pumping-engines, with a daily capacity of 15,000,000 gallons each; also for building and erecting a pumping-station near Shingle Creek; also for furnishing about 12,000 lineal feet of 30-inch cast-iron water-pipe. Specifications for pumping-engines and cast-iron pipe, and plans and specifications for the building can be seen at this office. Andrew Rinker, City Engineer, Minneapolis, Minn.

Building Intelligence.

We solicit from each and every one of our readers information relating to projected buildings in their locality, and should be glad to receive newspaper clippings and other items of interest.

YOUNGSTOWN, O.—The A Y & P R R Co are going to erect a handsome depot here to cost not less than \$10,000. Work will be commenced at once.

SPRINGFIELD.—Off Pine, 4 ten br block; cost, \$8,000; o, — Webster; a, F S Newman; b, D J Curtis.

NEWPORT, R. I.—Swedish church; Pastor, Rev Mr Hanson.

HADDONFIELD, N. J.—A Roman Catholic Church will be built here. Address Rev John M Murphy.

RHINELANDER, WIS.—Johnson Bros & Co. will rebuild their wagon factory and machine shops.

NORTH ATHENS (or Athens), TENN.—Hotel, br, stone and slate; cost, \$40,000; Athens Land and Mining Company; a, Thomas C Veall.

SPRINGFIELD, MASS.—Maple, alt on br and fr house; cost, \$15,000; o, P P Kellogg; a, Richmond & Seabury; b, L H Scott and J S Sanderson.

HOLYOKE, MASS.—Mill: cost, \$12,000; o, Conn River Lumber Co; o, Otto Swatthen; b, not known.

Alt high school; cost, \$5,000; a, J H Clough; b, not known.

INDIANAPOLIS, IND.—N Delaware, br bld; cost, \$7,000; o, Henry Coburn; a, L H Gibson; b, M K Fotout.

N Delaware, br bldg; cost, \$6,000; o, C E Kruly; a, L H Gibson; b, Shover & Christian.

HUTCHINSON, KAN.—Nothing to report over \$7,000.

FREETOWN, MASS.—At a town meeting held in Freetown Saturday it was voted to build a new town hall.

JACKSON, TENN.—A spoke factory will b. built here.

CHATTANOOGA, TENN.—A \$150,000 hotel will be built on Lookout Mountain.

STAMFORD, CONN.—Bus block, Pacific st. o, John Ryle; contract let; m, Daniel O'Connell.

Bus block, Pacific st; o, C F Miller, m, Edward Willett.

Bldg, Main and Pacific sts; o, Mr Pitts; b, Eugene Mead and S A Gregory & Co.

Bus bldg, Main st; o, S Adams; a, Henry Woodman; cost, \$17,000.

EAST HARTFORD, CONN.—Dw; o, Benjamin Dart; b, J M Bragg.

GREENWICH, CONN.—Village: o, Dr L Mason; a, W M Coats, of Brooklyn, N Y.

STAFFORD, CONN.—Mineral Springs Co bldg; b, P B Johnson, steam heat.

SELMA, ALA.—New school bldg: address Mayor Haas.

WORCESTER, MASS.—Nothing to report this week over \$7,000.

MILWAUKEE.—The Montreal River Co are erecting a large saw-mill to cut 100,000 feet of lumber per day at Gile, on the Mil, L S & W R'way, in the town of Vaughn, Ashland County, Michigan.

SPRINGFIELD, MASS.—Mulberry st, fr dw: cost, \$12,000; o, H H Bowman and T W Ellis; a, Otto & Bellinger; b, J D Curtis, mason; Stuart, carpenter.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1887, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 16.
NUMBER 23.

PUBLISHED EVERY SATURDAY.

NEW YORK, NOVEMBER 5, 1887.

LONDON, NOVEMBER 19, 1887.

SINGLE COPIES, TEN CENTS.
Subscription, \$4.00 per year in advance, post paid. IN AMERICA
SINGLE COPIES, SIXPENCE.
Subscription, 20s. per annum in advance, post paid. IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, conducted by HENRY C. MEYER, is published every Saturday at 82 & 84 Fulton Street, New York. Its opinions upon all technical subjects are either prepared or revised by specialists.

TERMS, \$4 PER YEAR, IN ADVANCE.

Postage Paid.

OFFICE IN GREAT BRITAIN,
92 & 94 FLEET ST., LONDON.

TERMS, 20s. PER YEAR, IN ADVANCE. Postage Paid.
SINGLE COPIES, SIXPENCE.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York), and crossed — & Co.

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 20, Leipzig, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, \$5; China, Japan, Sandwich Islands, Mexico and Cuba, \$5; South America, \$5. The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us promptly of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

LINING AN AQUEDUCT WITH LEAD.

THE aqueduct of Arcueil, which brings the waters of the Vanne to Paris, giving a daily supply of about 110,000 cubic metres, has for some time been a source of anxiety, owing to the fact that numerous small fissures had formed in it, the leakage from which endangered the foundations. In the early part of this year M. Humblot, the Chief Engineer of the Service, decided to stop this leaking by lining the interior of the aqueduct with lead for a length of 690 metres, and this has been done.

The sheets of lead used for this purpose are two millimetres thick and measure 4.8x2 metres. They are placed so as to overlap and are molded to the interior of the tube, which is circular and 2.10 metres in diameter. The upper edges of the sheets are 0.10 above the surface of the water in the duct. This has proved effectual in stopping all leaks. The total cost of the work was 52,500 francs. The question as to whether this mode of treating the duct would give rise to danger of lead-poisoning on the part of those using the water was a very interesting one.

The French chemists consulted on the subject were of the opinion that the amount of lead taken up by the comparatively pure water of the Vanne, flowing in an almost constant stream through the tube, would be so small as not to be a source of danger, but M. Humblot decided, as an additional precaution, to cover the inner surface of the lead sheathing with a thin layer of Portland cement.

Dr. O. du Mesnil, in a paper on this subject in the *Annales d'Hygiene* for October, 1877, from which the above data are taken, states that after the completion of the work in July last careful tests of the water passed through the tube were made by a competent chemist, M. Schutzenberger, with the result that he was unable to detect any appreciable quantity of lead in 50 litres of such water.

The expedient adopted appears, therefore, to have been entirely successful up to the present time. The results as determined two or three years hence will be very interesting, for there is room for doubt as to the expediency of the Portland cement lining of the lead with reference to the production of erosion of the metal surface, and this trial is on such a large scale that it will probably settle the question.

DESTRUCTION OF A WATER-TOWER AT FRANKLIN, MASS.

ENGINEERS and others connected with water-works, especially those in which an elevated tank is used for a reservoir, will be much interested in the account on another page of the destruction of such a tank which occurred October 27 last at Franklin, Mass. The description was written by a representative of this journal who visited the scene of the accident very soon after its occurrence, and the illustrations are from sketches and photographs made by him on the spot.

What caused the disaster is not definitely known, but we are inclined to the opinion that the weight of water in the tank, which was being filled for the first time after being raised as described, compressed the green masonry and blocking on which the tank rested.

This settlement broke the rising pipe, probably in the bell of the elbow at the bottom, shown in the sketch, which was afterward found to be frac-

tured, and which would naturally be the part most strained by it.

This would account for the instant loss of about forty pounds of pressure at the pump, and the water from the tank and from the pump, until it was stopped, would rush out into the masonry chamber. If its impetus was not sufficient to destroy the green walls, with the great superincumbent weight upon them, it would very soon burst them by its pressure, as the only door leading from the chamber was closed.

With the destruction of the walls the tank of course would fall and be violently ruptured on striking the ground by what water remained in it, for not half of the water could have run out before the walls burst, if this theory is correct.

A sample of the plate-iron obtained from the superintendent of the works is somewhat laminated and crystalline, but is perhaps good enough for tank-iron, although we may investigate that point further. The tensile strain on the perpendicular joints of the lower sheets is much higher than we should consider at all safe, as may easily be calculated from the data given, but it is still so far from causing rupture that we are not inclined to consider that the proximate cause of the disaster.

By a curious fatality, another water-tank, erected and owned by the same party, burst on the same day in Seneca Falls, N. Y.

We have sent another representative to that place, and give our readers his preliminary report elsewhere in this issue. We expect to give more detailed information next week, and until then we shall postpone further comment.

THE last number of the *Gesundheits Ingenieur* contains a paper by Professor Dobrowslawin, of St. Petersburg, on the comparative use of gas and electricity for lighting theatres. Referring to the interesting experiments made by Professor Pettenkofer and Dr. Renk, Professor Dobrowslawin, with the assistance of Drs. Kowolkowsky and Bosaroff, made, last February, during the three days' carnival at St. Petersburg, when the largest crowds fill the theatres, experiments on the temperature and ventilation of the "Grosse" and "Alexander" theatres, lighted with gas, and the "Mariar" theatre, lighted with electricity. These three theatres gave, each, two performances daily, and each held about 1,600 people. The thermometers were so placed as to be on a level with the audience. The carbonic acid was determined by the Pettenkofer method. As every theatregoer knows, the temperature falls between the acts, and it was found that the temperature in the galleries did not fall as rapidly as in the parterre. As a result, the Professor thinks that people seated in the parterre are more apt to take a cold than those in the upper parts of the house. The highest degree of temperature by electric-lighting was 25° C., and with gas 33° C. The Professor does not think that the difference of air is noticeable with either kind of lighting. Finally, the Professor concludes that electricity is far superior to gas from the standpoint of health.

THE BOOM AT LOS ANGELES, CAL.

AS EVIDENCE of the large ideas now prevailing in Los Angeles, Cal., we find a description in the *Express* of that city of a proposed scheme of sewerage involving the construction of 200 miles of sewers at an estimated cost of \$2,000,000.

At a point eight miles from the city 6,000 acres of land are offered the city for use, without cost, as a sewage-farm, with a guarantee of \$100,000 profit from its sale after development. This portion of the line will require some 8,000 feet of tunneling through the hills. We hope this enthusiastic promoter may not be disappointed in his anticipated profits, and it is possible that in a country where irrigation is essential to success in agricultural matters his expectations may be well founded. It may be well to remember that the balance is almost always on the other side of the ledger. As Mr. Rudolph Hering has been called upon to report upon the plans, they will doubtless be thoroughly sifted before being put into execution. We shall watch further developments with interest.

CINCINNATI'S WATER-SUPPLY AND TYPHOID FEVER.

THE old story of typhoid and malarial fevers from impure water is being retold just now in

the most prominent men in the profession, yet he has died comparatively a poor man, and many of his friends think his claim against the United States Government for extra professional services should be pushed. This claim is based on the fact that Mr. Walter was employed for one specific work, and while in Washington designed and executed the other Government work, for which he never received one cent. This claim amounts with interest to the sum of \$113,000, and it has been favorably acted on by the Commissioners of Claims at Washington.

Mr. Walter has been for so long an honored member of the architectural profession of the country, enjoying a great reputation for his work, that it seems to us that the American Institute of Architects should appoint a committee to inquire into this claim, and having satisfied themselves of its justice, should then take steps to secure its payment by the United States Government as a just debt.

THE meeting of the American Society of Civil Engineers this week was of more than usual interest, the feature being Mr. Buck's paper describing the work of

and that in its columns was the entire feasibility of heating by steam from the locomotive first demonstrated.

The Emerson system has been adopted by the Atchison, Topeka and Santa Fe Railroad, and its cars are being fitted therewith as rapidly as possible.

The Gold system has been adopted for all cars on the Manhattan Elevated, the Suburban Rapid Transit, the Inter State Rapid Transit, the Hoboken Cable Railway, and the Providence, Warren and Bristol. Part of the cars on the Boston and Providence are being equipped with it, and orders for equipment have been received from the Long Island Railroad and the Central Railroad of New Jersey.

The Martin Anti-Fire Car-Heater Company has made a contract with the New York Central Railroad covering their entire system.

The Safety Car Heating and Lighting Company have received orders from the New York and New England Railroad for their apparatus for thirteen cars, and this road has concluded to adopt it for their passenger system. In addition, the Northern Pacific has ordered it for fifteen cars, the Wagner Palace-Car Company for twenty, the

RESIDENCE OF E. W. DAVIS, ESQ., NARRAGANSETT PIER, R. I.—BRUCE PRICE, ARCHITECT

press dispatches from Cincinnati with unusual emphasis. This is attributed by the Health Officer, Dr. Stanton, to impurities in the water-supply, which, as our readers know, is taken from a point on the Ohio River which receives the surface wash from several miles of thickly-peopled country and is said to be liable, through eddies, to be sometimes contaminated by the city sewage. This state of things is aggravated just now by a long season of low water, but it is only a question of time when the intake of the water-works will have to be moved to some other point.

THE LATE DR. THOMAS U. WALTER.

WE elsewhere give a brief account of the career of the late Dr. Thomas U. Walter, until recently the active President of the American Institute of Architects. It is a fit time to call the attention of the institute to a matter in which Mr. Walter's Philadelphia associates are deeply interested—namely, his claim against the United States Government for extra services. We are advised from Philadelphia that although Mr. Walter has been one of

replacing the stone towers by iron ones at the Niagara River Suspension Bridge, an abstract of which we give elsewhere in this issue. A pleasant incident was the tribute by Mr. Theodore Cooper, a specialist in the same branch of engineering as is Mr. Buck. He expressed his appreciation of the magnitude and difficulty of the unique work performed, the skill with which it had been done, and the straightforward modesty with which it had been described, so as to make it appear a very simple matter after all, which sentiment elicited enthusiastic applause. Mr. Cooper also alluded to the fact that showy but comparatively simple engineering feats were heralded through the daily press from one end of the land to the other, while this work of Mr. Buck's, unprecedented both in its magnitude and its methods, had received no mention.

CAR-HEATING FROM LOCOMOTIVE.

THE following items will be found of much interest, as showing what is being done to supply a just and widespread public demand for safety in winter traveling.

It will be remembered that it is now nearly six years since this journal first advocated this much-needed reform,

Chicago and North-western for eleven, and the Delaware and Hudson Company for eight, and a number of others have given sample orders.

We shall be glad to inform our readers, from time to time, of any other railroads whose managers avail themselves of any one of the several systems of car-heating from locomotive now on the market.

A REPORT of an unusual and very pleasant incident reaches us from England. It is announced, in connection with the shocking accident that happened, owing to the negligence of the driver and stoker of the train on the Manchester and Sheffield Railway, by which the company have become liable for a large amount, owing to loss of life, that the workmen in the company's employ have offered to forego one week's wages towards the expenses. It should be added that the company is not a prosperous one.

OUR ARCHITECTURAL ILLUSTRATIONS.

HOTEL POURTALES, PARIS, FRANCE.

RESIDENCE OF E. W. DAVIS, ESQ., NARRAGANSETT PIER, R. I.

THE ENGINEERING & BUILDING RECORD ILLUSTRATED SERIES.

HOTEL POURTALES. PARIS, FRANCE.

THE TRINIDAD PITCH LAKE.

THE control of this celebrated deposit of bitumen seems to have passed into the hands of Mr. Barber, of the Barber Asphalt Paving Company, and Mr. Greig, of London, under the style of the New York and Trinidad Asphalt Company, they having the sole right to export for a period of fourteen years on payment of an export duty of 6s. 8d. (£1.60) per ton, which shall produce a minimum revenue of £10,000 per annum. And it is further provided, that in case the export duty produces an aggregate of £168,000 during the fourteen years, the lease shall be renewed for seven additional years.

It was proposed to throw the exportation open to all on payment of the export duty, but, as noted, this was not done. Excepting a subscription of \$500 towards the Victoria Institute by the gentlemen obtaining the concession, no reason is given for the change in the plan.

It is probable that most of the large users of bitumen have made arrangements for this supply with the New York and Trinidad Company, because the annual purchasers of only 25,000 tons of bitumen, out of the 180,000 tons represented, objected to the contract.

UNWISE ECONOMY IN THE CITY OF LONDON
—A LARGE TRACTION ROPE.

(London Correspondence.)

THE economists of the Corporation of the City of London have just scored a success in the shape of a resolution which does them very little credit. At a meeting of the members of the Corporation it was decided, by a majority of three votes out of 172, that the post of City Architect, vacated by the decease of Sir Horace Jones, should not be filled, but that a surveyor should be engaged at a yearly salary of £800 (\$3,840), whom they considered would be competent to give attention to the general and minor details of architecture. In the event of any large public work outside aid could be sought, the remuneration being by commission. Notice was given of a motion to rescind this resolution at the next meeting, on the ground of surprise and the fact that eighty-three Aldermen did not vote. It remains to be seen whether this backward step will be confirmed. The idea of the economists is apparently that all the public buildings that are necessary in the city have been erected, and that therefore an annual saving of £1,000 (\$4,800), which would result from this change, would be justifiable. They have, however, lost sight of such works as the new Criminal Courts, the approaches to the Tower Bridge, and other imminent changes.

If the temporary triumph of these cheese-paring gentry is confirmed, we shall probably next hear of Colonel Haywood being deposed from his position as City Engineer, on the ground that the works of paving and drainage in the city have now been carried out and that necessary repairs could be effected by the means of ordinary builders and plumbers. However, the general body of members of the corporation have generally been credited with more sense than is indicated by this foolish policy.

The traction rope destined for use in the new cable tramway in Birmingham has just been completed and delivered by the makers, J. & E. Wright, of Birmingham. It consists of two coils, each two miles in length. The circumference is $3\frac{3}{4}$ inches, and the breaking strain 33 tons. The ropes are constructed of six strands, each strand of 19 wires. It is stated to be one of the largest wire ropes yet made by any firm.

The foundation stone of Liverpool University College has just been laid by the Mayor. In connection with this college there is a technical department, for which Mr. Thomas Harrison, of Liverpool, has endowed an Engineering Chair with £10,000 (\$48,000), and Sir A. D. Walker £20,000. No other town in Great Britain has a chair that has such magnificent gifts made by local men, or otherwise, towards technical education.

IRRIGATION IN SOUTH AFRICA.

SOUTH AFRICA is in general an arid country. The Boers, and the natives before them, practiced irrigation in a small way, but no large work was undertaken until Mr. John George Gamble, M. I. C. E., built a reservoir in the Northern Karroo, known as Van Wyk's Vley. This reservoir has a catchment area of 460 square miles, on which the annual rainfall was only six inches. To take advantage of a natural valley for an overflow, the reservoir embankment, which is of earth-work with a puddle-core, was raised so that the capacity of the reservoir is 35,000 million gallons, or equal to a 5-inch run-off from the whole

catchment area, more, it was thought, than is likely to be gathered while the reservoir is used for irrigation, unless several wet years occur in succession. The earth-work amounted to 80,000 cubic yards, and is faced with 12-inch pitching on 18 inches of broken stone, this depth being taken to prevent crabs working into and through the bank. The supply-pipes are taken through a masonry culvert sunk in the solid shale on one side of the valley, the culvert being plugged with Portland cement concrete from the valve-tower to past the puddle core. The total cost, without land compensation, was £18,000.

No irrigation was attempted in 1884, the first year after completing the dam, and in 1885 only twenty acres were cultivated experimentally, but the amount of land under irrigation has grown very fast, and where formerly but a few sheep could find pasture large numbers of farms are congregated, with thousands of sheep and cattle; and as 100,000 acres are available for irrigation a township will be laid out there. The water drawing for this season's crop seems to have very small effect on the water which has accumulated, and there is a call for additional reservoirs in that part of the Cape Colony.

As South Africa has, for a long time before the discovery of gold, imported grain and flour, the necessities of the gold-diggers, in addition to those of the Boers, will doubtless furnish a market for the produce of all the land that can be irrigated.

FAILURE OF A STAND-PIPE AT SENECA
FALLS, N. Y.

OUR representative sent specially to Seneca Falls to report on this disaster sends the following preliminary report, which we hope to supplement by further details in our next issue.

Thursday, October 27, at 3 P. M., the large stand-pipe maintaining head for the public water-supply of the town of Seneca Falls, N. Y., was destroyed by bursting. Our special survey and investigation at the scene of the disaster has developed all the facts and conditions necessary for its presentation.

The structure was a simple steel cylinder 30 feet in diameter by 130 feet high, without a suspicion of braces, reinforcements, guys or anchorage, made of boiler-plates $\frac{1}{4}$ -inch thick at top increasing to $\frac{3}{8}$ -inch at base, riveted to flanged bottom-plates and erected like a tall cheese-box, on a platform a foot or two greater in diameter, made up of three courses of rubble masonry; the lower two laid up dry, the top course and a 3-inch bed asserted to have been laid in Rosendale cement. This was the entire structure, a 12-inch hole in bottom plate serving as inlet and

feet above surface of ground there. Had the disaster occurred, as it well might have chanced, in a thickly-built neighborhood, the loss of property would greatly have exceeded the \$20,000 now estimated, and have been accompanied by loss of many lives.

The detailed description of materials, fractures, workmanship, etc., will be more intelligible when accompanied by the drawings of tower, map, and location of fragments, sketches of dismembered sections, fractures, etc., which are in preparation for our next issue.

This stand-pipe was built by contractor R. F. Hawkins, Springfield, Mass., for George H. Norman, Boston, Mass., who owns and maintains the water-works plant and receives payment from the town for its use.

DESTRUCTION OF A WATER-TOWER AT
FRANKLIN, MASS.

THIS steady-going town of 5,000 inhabitants is in Norfolk County, twenty-eight miles from Boston on the New York and New England Railroad, and is supplied with gas, water, and electric-lights. Straw works and shoddy mills are the chief industries of the place, and the Dean Academy furnishes the largest and most imposing building. Water-works were built in 1884 by George H. Norman, Esq., who is the principal stockholder in the Franklin Water Co. Water is taken from a well by three Knowles pumps and forced through cement-lined mains to a tank, built by the Whittier Machine Co., of Boston, forty feet in diameter, which before the recent alterations rose thirty-five feet above the hill on which it stood, this hill in turn being about 150 feet above the pumps.

The pressure on the mains having proved too light for fire service, the company decided to raise the tank forty-five feet. The work of raising and of building brick walls to sustain the tank in its new location was begun about eight weeks ago, and went on steadily and successfully until the morning of Thursday, October 27, when at 2:10 A. M. the structure fell and now lies a complete wreck. Briefly stated, the conditions at the instant the accident took place were as follows, as nearly as can be learned from inspection and inquiry on the spot. The tank was resting on the outer walls, which were sixteen inches thick, except at the bottom, where they were three feet in thickness, these walls forming a cylinder thirty-six feet outside diameter, with sixteen pilasters projecting four inches from the walls; it was resting on the inner walls, which were twelve inches thick, forming a cylinder twelve feet in diameter, and it was resting also on the jack-screws and blocking, which were as they had been for the previous three weeks—that is, with a slight strain upon the screws. The tank was held at the top by four wire-rope guys. There was about twenty-five feet

outlet, and the overflow gushing over the upper edges at will.

The collapse has been absolute, and a more complete wreck is unimaginable, the sections and fragments shattered, twisted, and hurled in great masses up to 175 feet away. There was no wind when the burst occurred, and an eye-witness says the explosion was followed by a gush of water on the north-west side (nearest him), 8 feet from the bottom, and then the slow swaying and fall of the upper part of the cylinder. A section of 90 feet of the top of the cylinder was cut off and thrown out so that the nearest part of the bottom is 27 feet from foundation-wall and lies there flattened and destroyed by the fall. The lower 40 feet of the cylinder was completely demolished and thrown in every direction in not less than sixteen principal pieces, which cut down trees and ploughed great furrows in the earth. Segments of the lower courses of plates struck the bottom of the tank and tore several gashes through the steel plates. The inundation was severest to the south-west, sweeping away much of the mortar-laid foundation of a frame house 350 feet away, and extinguishing fires three

of water in the tank, and the pumps were in motion putting in more water at the rate of about 400 gallons per minute, the water-gauge at the pump showing from 100 to 105 pounds per square inch. The pump had been running at this rate since six o'clock, Wednesday, P. M., and the gauge had been steadily rising, as it should, with no apparent shocks. At 2:10 Thursday morning the engineer, who was watching the gauge, saw it suddenly drop to 60, and the pump start off at a terrific speed. He shut off steam and notified the superintendent.

An inspection of the ground at the hill showed the main body of the tank torn, and lying unrolled across the field-stone underpinning (Fig. 1). The bottom is in five pieces, one lying on the west slope of the hill, about 200 feet from the foundation; the other four were on the eastern slope, and 50 and 75 feet away. The largest piece of the five—about one-half of the bottom—

was lying *upside down* about 150 feet east from the foundation, and was so covered with bricks and timber that it could not be thoroughly examined. The bricks and timber were carried in every direction down the hill, but no damage of any consequence was caused outside of the structure itself. The brick walls were completely demolished, a few patches of the first course being all that can be seen of the bricklayers' work.

The tank stood on a hill where an outcrop of rock afforded a perfect foundation, and the underpinning,

which was of field stone laid in cement mortar, was in no way affected by the accident.

The raising was done by Isaac Blair, of Boston, by contract, and the brick-work by Charles H. Corbin, of Franklin, by day labor. Before beginning the work of raising, the tank was emptied and the town supplied by direct

During the lifting the centre of the tank bottom "buckled" up an inch. The brick-work was carried along as the tank rose and when the walls were brought up to a bearing on the I-beams the bottom brick-work was four weeks old. The mortar was of cement, lime, and sand; in just what proportions could not be learned. After the accident at least one-half of the 180,000 bricks that were scattered about had little or no mortar on them, while to the others the mortar was reasonably adherent.

The upper courses of brick had been finished only a few days when the tank was allowed to partially rest upon them.

The tank was single riveted throughout. Some of the sheets forming the bottom near the circumference were $\frac{3}{8}$ of an inch thick, but most of them would measure only $\frac{1}{8}$ of an inch. The barrel was seven sheets high—35 feet

—the lower four being $\frac{1}{8}$ of an inch and the upper three $\frac{1}{4}$ of an inch thick. Midway around the inside of the tank was a ring of 3-inch T-iron, and the top edge was stiffened by a 2-inch angle-iron.

The bottom was joined to the barrel by 4-inch angle-iron, and a broken piece showed a thickness of $\frac{1}{2}$ -inch at the angle. In all of the bottom that could be examined the barrel sheets had been wrenched outwardly from the angle-iron.

At some places the barrel sheet was completely torn away; in others the tear was through the rivet holes, at others just above the angle-iron, and in others the angle-iron itself was broken.

pumping. Holes were cut in the underpinning to allow 18 jacks to be placed about the circumference, and by suitable blocking the tank was raised five feet from its original position. A flooring of hard pine planks $5\frac{1}{2}$ inches thick was then put under the bottom and supported by 16 9x4 I-beams, placed radially, and four of them tied diametrically, as shown in plan. These I-beams were kept apart by hard pine braces, and were supported by timbers so placed as to form a hexagon just inside the outer brick wall, and these in turn rested on 23 jacks and the blocking. From the 5-foot to the 25-foot level above the underpinning, seven men worked the jacks, but at that level three men were taken off, and four carried the tank to its 45-foot level.

Water was supplied to and drawn from the tank by a single pipe of 12-inch cast iron, which entered the structure on the west side, and was rigidly bolted to the bottom of the tank about six feet from the circumference. This pipe was broken off about two feet below the top of the underpinning at the bell of the bottom elbow, and the lower end was thrown out to the west with sufficient force to cause the top end to fall not more than ten feet east of the bottom elbow, and at the time of the accident the door of the new brick tower was closed.

[We take pleasure in saying that the superintendent, Mr. W. E. Nason, was exceedingly courteous and rendered our representative every aid in his power in the work of collecting the foregoing facts.]

THE CAPE COD SHIP CANAL.

THE Cape Cod Canal has been before the public for many years, and several companies have held charters for it, but have given up either for want of funds, bad management, or some other cause without leaving any traces on the ground.

A company, incorporated in 1870, came to trouble by a series of underlettings. About 1880 the job of digging the canal was started by sub-contractors with Italian laborers, but there was some difficulty about the pay, and this ended in a riot, which the militia was called upon to quell.

The present company succeeded to the rights and titles of its predecessors after paying all the damages caused by the riot and the labor bills. It has spent several years in building a dredge and making surveys. The dredge has been in operation some six months or more, having been considerably altered over, as it was found to be at first too light for its work.

When all was in working order it was found that the charter was so near expiring that capital could not be obtained to carry out the work. The Massachusetts Legislature has, however, just renewed the charter to the present company, and it is expected that the waterway will be opened within three years.

The site selected for the canal is a narrow valley (see Fig. 72) running across the peninsula from Barnstable Bay on the north to Buzzard's Bay on the south. At each end there is a small stream running through the valley, and for most of the distance the marsh is about three feet above high tide. The canal is to be 200 feet wide at water-line and 28 feet deep, being 75 feet wide on the bottom, with turn-out stations 150 feet on bottom. The bottom is to be 22 feet below mean low tide and 32 feet below high tide.

The line of the canal will present three curves of some 7,000 feet radius. It will be $7\frac{1}{2}$ miles from shore to shore, or about nine miles including the channel in Buzzard's Bay out to Wing Neck Lighthouse. The natural conditions are such that there is only one short section of cutting much above tide marsh. This cut is 39 feet above the tide for a short distance; most of the cutting will be from two to three feet above tide level.

At present the line of the Old Colony Railroad crosses the canal line at three points on the main Cape line and once on the Wood's Holl branch.

The Canal Company propose to rebuild a part of the railroad so as to have but one crossing, as shown in dotted line on plan, and have obtained the consent of the railroad company to the change. This will necessitate one draw-bridge and for public way some system of ferries will probably be established, with possibly one or two bridges. It will be necessary to build dykes at the Barnstable Bay end to keep the entrance clear, owing to the currents which follow the shore and are constantly changing the outlets to the different streams entering the bay. The United States Government has had under consideration a project for building a harbor of refuge somewhere on this coast, and the large tracts of low marshes near the line of canal present a very favorable location for it here.

The difference in tides of the two bays is about five feet of height and $3\frac{1}{2}$ hours difference in time, and it is estimated that the maximum current due to tide will not be over four miles per hour.

Mr. F. A. Lockwood is the builder and contractor for the dredge described above. Charles M. Thompson is the engineer having charge of all the work of surveys, soundings, etc. He has made a large series of tests by pits and wells, and finds that the material is marsh muck, sand, and clay. Some few boulders will probably be met, but no rock or ledge has been found or is likely to exist.

Total amount of excavation estimated, 11,500,000 cubic yards. At the present time the dredge has excavated some 1,200 feet of channel the full width and from 12 to 18 feet deep.

The officers and directors of the Cape Cod Canal Company are: President, Hon. W. A. Clark, Jr.; Treasurer, Samuel Fessenden; Directors, Edwin Reed, William A. French, Sidney Dillon, Gen. Charles C. Dodge, Thomas Rutter; Engineer in Charge, Charles M. Thompson; Contractors, F. A. Lockwood, Boston; Smith & Ripley New York.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

No. XXIV.

(Continued from page 582.)

THE LOCKWOOD DREDGE—CAPE COD SHIP CANAL.

Most of the harbors of this country are of natural formation, requiring comparatively small amounts of dredging, and this mostly for the purpose of removing bars, deposits brought down by rivers or sewers, and keeping the channels clear. This kind of work has brought out a quantity of different styles of dredges of the clam-shell and scoop type, having an intermittent compound motion by which a scoop or grab is lowered into the material to be removed—pressed into it—then raised and emptied into scows; simulating to a certain extent manual labor.

In Europe most of the large harbors are formed artificially, necessitating large amounts of dredging and excavating, and for this purpose continuous or bucket-dredges have been of almost universal use; but they are of comparatively recent introduction in this country.

The dredge now at work on the Cape Cod Ship Canal, at Sandwich, Mass., though an outgrowth of the Hercules type, differs from it in many essential parts. Being the first of its kind built, it naturally has been considerably altered in details from its first design. We present two general views, Figs. 73, 74.

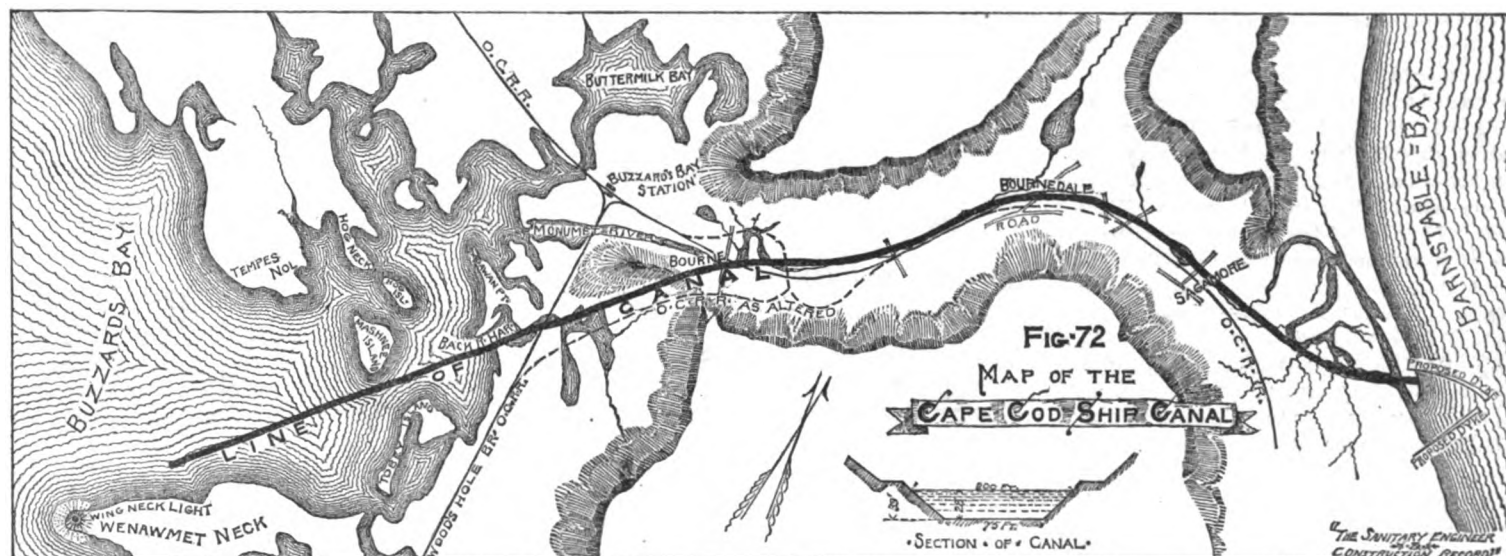

It was designed and built by F. A. Lockwood, of East Boston, under the patents of J. A. Ball, of Oakland, Cal.

In a general way it consists of a large flat-bottomed barge, decked over and containing all the boilers, engines,

it is carried to the shore by a system of pipes and water-carriage.

First—The first distinctive feature of the Lockwood dredge is the fact that the chain and buckets revolve so as to attack the material from the top on the *downward* motion, thus bringing the weight of the buckets and the laws

Second—Most other dredges and excavators have their chain revolving on a drum at top and bottom of a bucket-ladder, with intermediate rollers to support the chain. In the Lockwood dredge the chains are formed with a series of castors which run on a track like a train of cars, and the lower end of the bucket-ladder is simply a curved track in

and pumps for working the dredge. Fig. 75 is a general plan of lower deck of the barge. Fig. 76, a plan showing framing. Fig. 77, a general view looking down. Fig. 78, a sectional elevation. From the barge rises a tower with a raised platform, supporting an endless chain with buckets which, as it revolves, continuously scoop up the material and deliver it to the top of the tower, from which

of gravity to the help of the motive power, and carrying the load under water as far as possible, thus reducing its weight. The Hercules and the European dredges work in the opposite direction, cutting the material on the upward motion. The large European excavators used on land, many of which are at Panama, work, however, on this principle of the down stroke.

a vertical plane. The details are shown in Fig. 79.

Third—The bucket-ladder is in two sections, Fig. 78. That part above water is stationary, and only the part in the water is movable, and can be raised or lowered according to the depth of excavation necessary. Two positions of the ladder are shown.

Fourth—The material brought up to the top of tower may be delivered into scows by means of wooden shoots on either side, but is usually delivered into a hopper, where a strong stream of water breaks up the cakes and carries the stuff off through a pipe, which extends to the shore. No churn or cutter is used, the stream of water being sufficient to break up the material.

Fifth—One other novelty is the mode of propulsion of the dredge. At the extreme rear end of dredge is a projecting frame, on which are adjusted cast-iron sliding-collars. Through these collars is passed a large wooden spud, 18 inches in diameter and 80 feet long, shod with an iron shoe some 7 feet long. This being dropped into the bed of the canal, forms a centre post on which the whole apparatus can revolve, and by means of rack and pinion gearing the dredge can be pushed away from this spud (or drawn to it). When the collar has reached the end of the frame-work there is a second spud, just at the back of the dredge, which is dropped so as to hold the dredge in place, while the other spud is raised by means of a large pair of shears, then the collars are drawn in by means of the rack and pinions, and the spud is again dropped and the other one raised.

The Lockwood dredge, No. 1, is 80 feet long by 36 feet beam, and has a draft of some six feet. The working-deck overhangs the front of the barge some 20 feet, and there is a vertical slot cut in the same for the passage of the bucket-ladder.

The tower is some 60 feet above the bottom of the hull and is supported on six 12x12-inch wooden posts, with 12x12-inch braces from either side and ends.

The stationary track for buckets extends from top of tower to within 6 feet of the deck, and is formed of 8x8 and 12x12-inch joists and stringers. The movable portion, or bucket-ladder, is of iron; it is formed of two trusses, the top and bottom chords of which are converging, and are made of a 5x5x $\frac{1}{2}$ -inch angle-iron bent at the lower end on a circle of 10 feet diameter. At the upper end the lower chord is bent up on a $\frac{1}{4}$ -circle of 4 feet radius, and connected to top by a diagonal. The pivot on which the ladder hangs is located here. The panels of the truss are formed of 5x2-inch channel uprights and 3x2-inch angle-iron diagonals, and the two trusses are united by 3 $\frac{1}{2}$ x3 $\frac{1}{2}$ T-irons. That part of the ladder which passes through the opening in barge is made wider by extending the T-irons, and placing 5x2-inch channels outside of the angle-irons so as to steady it and keep the buckets clear of the sides of barge. The ladder has nine panels 6 feet on centres and is 63 feet over all, or 60 feet from pivot to point. The weight of the outer end of ladder is carried by chains, which pass over pulleys on the upper deck and connected by iron rods to an 8x8-inch timber on either side, which is 34 feet long. This timber has a rack on its underside which engages a pinion by which power is applied to raise or lower the ladder. Just above the location of the pinion is an iron roller which bears down on top of the 8x8-inch timber and keeps it in place. The rail on which the chain runs (the 5x5-inch angle-iron) has a bearing or wearing surface formed of plates of half-inch steel bolted on in short sections so as to be easily renewed.

The buckets, of which there are 30, Fig. 79, are of wrought iron, riveted to 3 $\frac{1}{2}$ x3 $\frac{1}{2}$ x $\frac{1}{2}$ -inch angle-irons and have a cutting edge of 6x $\frac{1}{2}$ -inch steel. They have a capacity of about 18 cubic feet. The bottom is separate and hinged to the chain, so that, as the bucket turns over the top drum, the material slides off of the bottom. There is an iron apron in front of each bucket to prevent material from dropping off as the bucket cuts into the bank. The chains, of which there are two each 234 feet long, are formed of plates of 4x1-inch iron in pairs alternately 16 and 11 inches long, riveted together by 1 $\frac{1}{2}$ -inch steel pins 5 $\frac{1}{4}$ inches long. Each set of 16-inch plates carry a 7-inch iron roller, or castor, on a 1 $\frac{1}{4}$ -inch pin. The two chains are connected by the roller-pins, which also pass through the different projections of the buckets, as shown in detail plans.

The power is applied to the chains by means of a pair of drums, or sprocket wheels, at the top of the tower. These are driven by bevel gears 30 and 20 inches on an 8-inch shaft 46 feet long, extending down to the engine-room.

The motive power is all located in the barge below deck. It consists of four boilers of the locomotive type set in pairs on either side, with coal-bunkers in the front end. They consume about one ton of coal each per ten hours.

The steam is supplied to two 75-horse-power reversible engines located amidships; cylinders, 12 inches, 24-inch stroke; speed, 75 revolutions in ordinary working. They are both connected to a single fly-wheel. Power is distributed from these engines by means of bevel gears to the different parts as required. The engines are connected to a 6-foot spur wheel, from which motion is transmitted by the 8-inch vertical shaft to the drums at top of tower. These gears are furnished with large friction cones and cast-iron friction boxes, so as to be slowed up as may be required. A counter-shaft carries power to the two sets of pinions, which by means of racks gives the sliding motion to the collar on the spud at rear of dredge. Another gear connects to the rack which raises and lowers the bucket-ladder. Still another carries the power forward to a pair of grooved capstans by means of which the front of dredge is made to revolve on the spud centre. A similar capstan is used in connection with the shears by which the spuds are raised.

The boilers furnish steam to three Blake pumps. These have a 10-inch suction and deliver 12 gallons of water per stroke at the rate of 60 strokes a minute. The supply of one of these pumps passes through the condenser, after which it joins the other supply and is delivered by a conical nozzle into the hopper at the top of tower. The force of the stream is sufficient to break up all the cakes of muck and clay so that it can be carried off by the water through an 18-inch iron pipe. There is also a small engine to furnish power to a dynamo for electric-light; this is to be used for night work and after dark in winter.

On the upper deck, twelve feet above the main deck, is located near the front the capstan mentioned above. This is formed of two grooved rollers over which a rope is passed four times and the ends made fast to shore. The speed of this is regulated so that each bucket strikes the shore just eight inches (laterally) beyond its predecessor. That is, each bucket takes a slice, two feet inshore and eight inches wide, the rope being drawn in on one side and let out on the other. By these means the dredge can swing around and dredge a channel of 125 feet. Just ahead of this capstan are the two pulleys over which the ladder chain passes. A painted scale on the deck shows the depth at which the

buckets are working. These chains allow the ladder to be lowered to a depth of forty feet.

The ladder is first set to dredge ten or fifteen feet deep, and when it has advanced as far as required it can work back and deepen the channel by lowering the ladder; or a second or third dredge may be started behind it, each cutting somewhat deeper. At the rear is the frame-work on which the spud collars slide in and out; also the capstan by which the spuds are raised. The lifting shears, which are twenty-five feet high, are held at the top by means of two iron braces bolted together at bottom and held in an iron frame made fast to the floor. This frame has a series

FIG. 77 GENERAL VIEW OF DECKS

DREDGE USED ON
CAPE COD SHIP CANAL

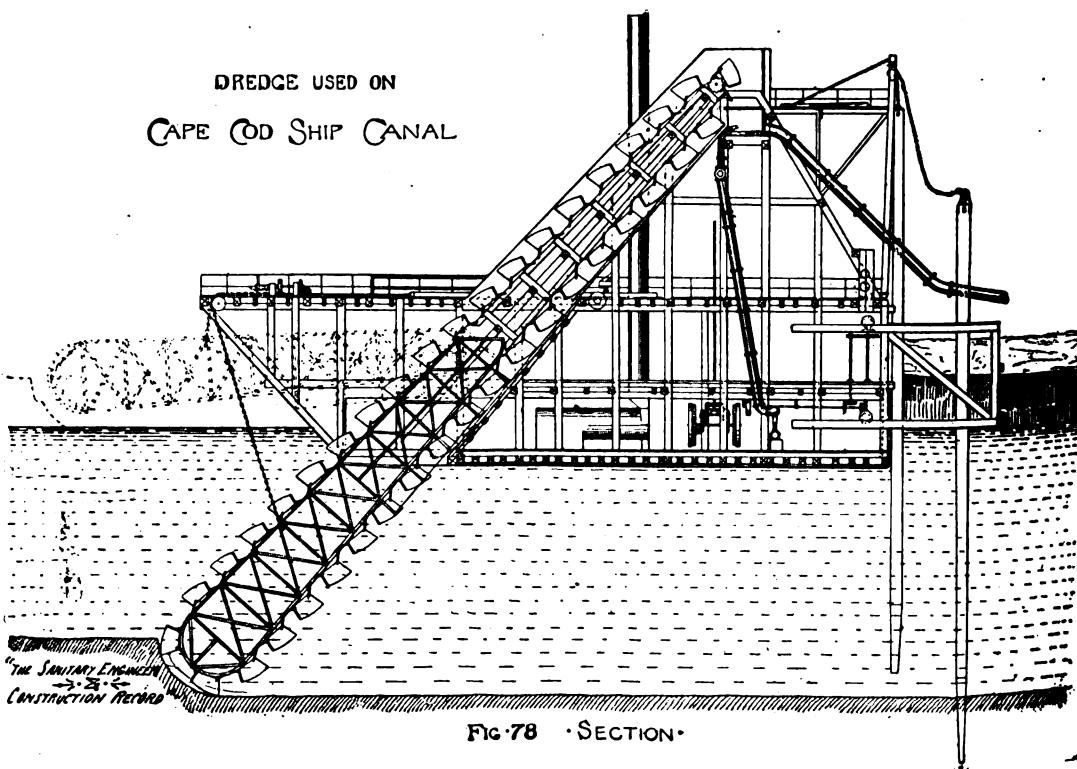

FIG. 78 SECTION

of hooks on which the bolt is caught so as to give the required inclination to the shears.

In ordinary work the buckets revolve at the rate of 14 buckets per minute and will deliver easily 4,000 yards per 10 hours.

The delivery pipe is eighteen inches diameter wrought-iron, with cast-iron flange joints and spherical unions. Each straight section beyond the dredge is placed on a float and the end carried over the top of the bank where the material is delivered, and the water flows away to some natural or artificial outlet. At Sandwich it is necessary through the marshes to prepare a small bank each side of

requisites of stability and strength; stability being the power of resisting forces tending to overthrow the structure, or to derange the parts of which it is made, from their proper relative functions; and strength, "the power of resisting forces tending to alter the figures of those parts or to break them in pieces."

It is evident, therefore, that the engineer to be proficient in his calling must inform himself on the special properties of the materials employed in constructions, whether earth, stone, brick, timber, iron, or other substance, as well as on the kind of treatment or workmanship to which such material may be subjected, and the form in which it can be most advantageously used. He must learn by practical experience of the action of materials under service and in all accidental conditions to which they may

the laws of river and ocean currents, the formation of sand-bars, etc.; the mining engineer requires knowledge of sinking shafts, of tunneling, must be familiar with geology, mineralogy, and chemistry; the mechanical engineer must be able to consider all questions of machines, motive power, etc.; the electrical engineer manages all matters in the application of electricity to the uses of man; the bridge engineer constructs bridges; and the building engineer, or, may we not say, the architectural engineer, takes up all questions in relation to the construction and strength of buildings.

Architecture, strictly speaking, is a fine art; as Fergusson expressed it, the "Queen of the Technic Arts;" "the art of ornamental and ornamented construction." While architecture has its "roots in pure utility," it is a question whether when the first shelters were constructed it was not engineering ability that accomplished it, architecture only developing when man began to ornament and to decorate his constructions in order to gratify his inborn "craving for beauty and love of proportion."

The pure architect begins where the engineer ends. Without the engineer the architect would give strength to his constructions merely by satisfying his eye and sense of proportion, leaving the rest to chance. So soon as he begins to work up the size of the parts for the loads they have to sustain, or to consider the strength of materials and the forces to be resisted, then he becomes an architectural engineer.

One may by study and experience become an expert on the subject of architectural engineering, yet never make an architect, lacking talent and artistic taste; but the field of the pure architect is a very limited one. All engineers cannot be architects, but all professing architects must be engineers, more or less, and the more ability one possesses in this line, the more chance for his success in the great constructions of the day. To quote Fergusson again: "It is not essential that the engineer should know anything of architecture, though it is certainly desirable he should do so; but on the other hand, it is indispensably necessary that the architect should understand construction." "Without that knowledge he cannot design." If he feels inability in this direction he should associate with one who can supply the deficiency and reserve to himself the artistic department of the profession. It is very seldom that perfect artistic and perfect mechanical ability can be found in a single person, though if one who is an engineer by education feels that he has this artistic skill, there is no reason why he may not make one of the best of architects.

It may be seen, therefore, that no strict line of demarcation can be drawn between engineering and architectural practice; that one merges into and becomes an essential part of the other, architecture being all the more beautiful and satisfying, as well as practically correct, when its lines correspond with the lines of engineering construction. "The one is the prose, the other the poetry of the art of building."

A NOVELTY IN BRIDGE ERECTION.

WE take from the *Wochenschrift des Oesterr. Ingenieur und Architekten Vereines* the following, contributed by Engineer A. Budau:

The machine works of Stabilimento forlivese (Italy) recently received the contract to build an iron road bridge, in one span, over the Montone River at a place called Passo del Braldo, about six kilometres from the city of Forli.

Material for temporary trusses not being obtainable, it was decided by the engineer, E. Forlanini, to build the bridge all on one bank, and then to push it across to the other side. It should here be mentioned that the Montone River is nearly dry in summer, but a flood of rushing waters in winter.

When the bridge was quite finished it was placed on two small cars, one under the river end of the bridge and the other under the shore end, as seen in the following sketch.

Long stringers supporting channel-iron rails were then placed on the bank and on the bed of the river for the car-wheels to run on. When all was ready, and the bridge ends fastened to the cars, the river car being surmounted by a scaffolding, the shoving or pushing of the bridge began. Two workmen armed with crowbars were at each car wheel, and they kept prying the structure across, no other power being used. The time taken for the work was seven hours. The bridge as shoved across weighed 59 tons.

the canal some three or four feet high over which the pipes are discharged. On the dredge the delivery pipe has a circuitous route, as it is necessary to pass around the spuds and yet leave the dredge on the centre line to allow of the swinging motion of dredge.

This dredge cost some \$125,000, of which about \$40,000 was spent in alterations and improvements. It is estimated that it can be duplicated from \$90,000 to \$100,000.

A force of twelve men is necessary to work the dredge, including engineers and firemen, and it is said to excavate at the cost of less than three cents per cubic yard.

(TO BE CONTINUED.)

WHERE THE LINE OF DEMARKATION BETWEEN ENGINEERING AND ARCHITECTURAL PRACTICE IS TO BE FOUND.

ABSTRACT of paper by Joseph M. Wilson, A. M., C. E., F. A. I. A., Mem. Am. Soc. C. E., Mem. Inst. C. E., London, Eng., read at twenty-first annual convention of American Institute of Architects, held in Chicago:

Engineering covers a broad field, said he. One eminent as a professor and writer on this subject, has said that "Engineering is the art and science by which the mechanical properties of matter are made to serve the ends of man," or, in other words, it is "the useful application of mechanical science to those ends." In the widest sense, almost every one is more or less a practical engineer—the man who makes a passage across a torrent by means of a fallen tree, as well as the man who constructs the most complicated piece of machinery, or rears a lighthouse on the most exposed rock of the ocean. Little or nothing can be constructed or built without encroaching on the province of the engineer.

The objects treated by the science of engineering may be classified under two heads, structures and machines, the latter being those "combinations of solid materials, whose parts are intended to have relative motion and to perform work." A machine may be a structure, but structures are not necessarily machines. In the words of the same writer, "The theory of structures, which is founded on the principles of statics, or the science of equilibrium, is divided into two parts, relating, respectively, to the two

be exposed, and by this experience he should be enabled to allow for all such conditions and for variations which may occur in the recognized properties belonging to these materials.

Engineering is an exact science and its application to any construction involves the principles by which the structure may be built, in the whole and in each part, according to the best design for accomplishing the uses to which it is to be adapted and for resisting the forces that must be sustained by it. The more nearly these conditions are fulfilled, the more efficient, durable, and economical the structure will be, and also to the educated or artistic eye the more beautiful, as the lines and proportions will be the best and truest to satisfy the purposes of the structure.

Engineering may be divided into two grand departments, civil and military. With the latter we need not now be concerned. Civil engineering, in its most general significance, may be said to involve those applications of mechanics and the arts of construction which treat of the formation and building of lines of transport for freight and passengers, whether by water, highway, or railroad; the construction of works for water-supply and drainage; the theory and practice of mining, and the formation of harbors and works for protection of the coast and for aid to navigation. All of these works comprise "combinations of structures and machines;" "structures in earth-works, as cuttings, embankments, and reservoirs; in masonry, timber and iron, as bridges, viaducts, aqueducts, tunnels, locks, basins, piers, and breakwaters; machines, such as carriages, locomotive and stationary engines, lock-gates, sluices, valves, pumping-engines, and dredging-machines." And in the "old days" the civil engineer was expected to be able to undertake all of these objects. In modern times, however, business has so much increased in each department that engineers can afford to devote themselves to particular subjects, and civil engineering is rapidly dividing into specialties.

One of these may be considered as involving "the laying out and constructing of lines of transport, and selecting the sites for works in the best manner possible with reference to the features of the country, so as to secure economy in execution and working."

Hydraulic engineering takes up the question of water-supply, and requires study of the laws of rainfall, the supply and flow of streams. Sanitary engineering comprises matters of drainage and ventilation; the engineer of coast works must understand the action of waves.

THE ENGINEERS' CLUB OF PHILADELPHIA.

A REGULAR meeting of the club was held October 15, 1887, Past President Frederic Graff in the chair; Mr. Howard Murphy, Secretary; 20 members and one visitor present.

Mr. A. Marichal presented a description of the Gileppe Dam, Belgium, illustrated by photograph and drawings, and followed by a discussion having for its object to prove that a saving of 50 per cent. of masonry could have been effected, together with an increase of stability, by adopting a profile taken from his "Diagram for the Construction of Reservoir Walls," presented to the club on May 21, 1887.

The Gileppe Dam was completed in 1879. The object of its construction was to supply the city of Verviers with water. The capacity is 3,173 million gallons. The dam is 49.2 feet wide at the top and 216 feet at the bottom; its total height is 156.6 feet. At the top the dam is 771 feet long and at the bottom 269 feet. It is built of rubble masonry, weighing $1\frac{3}{4}$ tons per cubic yard.

The dam is surmounted by an immense statue of a lion. This statue is composed of 183 pieces of sandstone. Its total height is 70.52 feet; the body is 16.4 feet wide and 52.5 feet long. One of the claws measures 5.31 feet and the length of the nose is 8.20 feet.

In concluding, Mr. Marichal made a graphical and analytical comparison between the profiles given by his above-mentioned diagram and those of some dams already in existence and designed by the most competent engineers.

Mr. A. Saunders Morris presented notes upon "Connections for Secondary Batteries."

Arrangements for connecting the elements of storage batteries have given some trouble, principally on account of oxidation. The best form of connection is one in which the joint is removed as far as possible from the acid, and which can be readily detached for the purpose of removing the element.

Several forms of binding posts or connections were exhibited, made of tough lead alloy. Both male and female threads are cast so that the castings are turned out of the molds, completely finished, at the rate of one per minute. The mold for casting the screws was also exhibited.

The Secretary presented, for Mr. W. H. Nauman, a description of tests for riveted joints, made at Watertown Arsenal, Massachusetts, for the Bureau of Steam Engineering, September, 1886, accompanied by very complete drawings and tables.

Mr. Henry Roeske, of Philadelphia, introduced by the Secretary, presented an illustrated description of a system of water filtration devised by him. He preceded this description by a historical sketch of the filtration of water and the various principal devices which have been used for the purpose of accomplishing it. Mr. Roeske's filter consists of a series of compartments so arranged that a large excess of water can be used for agitating and cleansing the filtering material in each compartment separately, while the rest of the compartments are furnishing a continuous supply of filtered water. The material in each compartment is designed to be cleansed at intervals of hours or days, as may be desired, by the action of automatic valves, which are operated by a lever formed of pipe, which fills with water at the designed intervals, and by its thus increased weight operates the valve. Sand and coke are the materials used. They are placed in separate compartments, the design being to protect the coke from the coarser impurities, so as to lengthen the time of its use. It is intended that the coke be used also as fuel after removal from the filter.

THE WESTERN ASSOCIATION OF ARCHITECTS.

THE next convention of the Western Association of Architects will be held in Cincinnati on Wednesday, November 16. A special rate of \$11.80 for railroad fare from Chicago to Cincinnati and return has been obtained. In order to secure this rate, it was necessary to guarantee that fifteen or more persons would go on one date and *via* the same line. The Monon route, L., N. A. & C. Ry., has been selected as the line to be used by the members and their friends from Chicago and the North-west. Special accommodations will be provided for ladies, and it is hoped that the delegates and their friends will bring the lady members of their families. J. F. Alexander, Lafayette, Ind., is the Secretary of the association.

THE WESTERN NEW YORK ASSOCIATION OF ARCHITECTS ORGANIZED.

A WELL-ATTENDED meeting of the architects of Rochester and vicinity was held in that city on October 29.

Among those present was a lady architect from Buffalo, Miss Louisa Bethune. Others were: Louis P. Rogers, James G. Cutler, John R. Church, Charles F. Crandall, W. H. Richardson, Orlando K. Foot, Jay Fay, W. C. Welder, W. Foster Kelly, O. W. Dryer, Otto Black, Thomas Nolan, Rochester; J. Q. Ingham, J. H. Pierce, Elmira; E. A. Curtis, Fredonia; E. M. Buell, George W. Baxter, Ellis G. Hall, C. E. Colton, J. H. Kirby, Asa L. Merrick, Syracuse; C. R. Percival, Cyrus K. Porter, W. W. Corlin, R. A. Bethune, Buffalo.

Louis P. Rogers, of Rochester was made temporary chairman, and R. C. McLean, of the *Inland Architect*, Chicago, temporary secretary.

After a report from the committee on by-laws had been received and approved, an organization to be known as the Western New York Association of Architects was perfected, with the following list of officers:

President, James G. Cutler, Rochester; Vice-President, Cyrus K. Porter, Buffalo; Second Vice-President, E. A. Curtis, Fredonia; Secretary, W. W. Carlin, Buffalo; Treasurer, C. E. Colton, Syracuse; Executive Committee, J. H. Pierce, Elmira; Louis P. Rogers, Rochester.

THOMAS U. WALTER.

THOMAS USTIC WALTER, designer of the extension of the United States Capitol, of the Girard College Buildings at Philadelphia, and other notable works, and for many years President of the American Institute of Architects, died in Philadelphia October 30, in the 84th year of his age.

Mr. Walter was born in Philadelphia September 4, 1804, where he received a fair education. When fifteen years of age he began his study of architecture, entering the office of William Strickland, who was the designer of the Custom House and the Mint in Philadelphia. He did not, however, complete his studies and engage in practice until 1830. The next year his design of the new County Prison was accepted, and but two years afterward he prepared the original designs for the Girard College building and was given charge of the construction. Previous, however, to commencing work on the building he was sent to Europe by the Building Commission, where he studied the architecture of Europe. On his return work at the college begun, and was finished in 1847, his plans having been followed throughout.

This work gained him a reputation, and he was employed by the Venezuelan Government to prepare plans for the construction of a breakwater at Laguayra, which he did. In 1851 he prepared plans, in competition with other architects, for the extension of the National Capitol buildings, which were accepted, and Mr. Walter was retained to superintend architectural construction, with General M. C. Meigs, U. S. A., as engineer. He removed from Philadelphia to the Capital, where he lived for fourteen years. While there he designed the extensions to the Treasury, Patent Office, and Post-Office buildings, and the great dome on the old Capitol, the Congressional Library, and the Government Hospital for the Insane.

In 1865 he returned to Philadelphia to live, and designed his own residence in Germantown, intending to retire from active practice. But financial misfortunes overtook him, and he was compelled to re-enter professional life, accepting the position of assistant in the architect's office of the Pennsylvania Railroad Company, where he remained until the commencing of operations on the public buildings of Philadelphia, when he became Mr. John McArthur's assistant, and so continued until his death.

There are many notable buildings in Philadelphia which he designed, among them being St. George's Hall, Preston Retreat. He always made a specialty of the classic antique style, and nearly all the buildings designed by him are of that style.

Mr. Walter was one of the original members and President, until the last meeting in Chicago, of the American Institute of Architects, at which time he was relieved of the duties at his own request, and the institute bestowed on him the office of honorary president.

He has been a member of the Franklin Institute of Philadelphia for nearly 60 years, and at one time was Professor of Architecture in it, and since 1841 has been a member of the American Philosophical Society. Besides

these he has been an interested member in a number of literary and scientific societies. In 1851 the University of Lewisburg conferred the degree of Doctor of Philosophy on him and Harvard College conferred on him the degree of LL.D.

Mr. Walter leaves a wife, two sons, and three daughters. The immediate cause of his death was a severe cold acting on the debility of old age.

ACCORDING to the *Deutsche Bauzeitung*, the "Krembsen Circus Building," in Berlin, which is built entirely of iron, was equipped complete in twelve days, with a hot-water heating apparatus. The pipes are so arranged as to run under each seat.

THE *Revue Industrielle* gives an interesting account of some recent experiments in England with the regular army powder and the Johnson-Barland smokeless powder. In one test a Martini-Henry rifle was used. The charge of ordinary powder used was 5.5 grammes, which gave the bullet an initial velocity of 400 metres. With the Johnson-Barland powder the charge was 3.9 grammes, which gave a velocity of 463 metres. A second test, made with two Martini-Enfield rifled cannon, showed that the regular powder fouled the gun so much that it had to be cleaned, while the Johnson-Barland powder hardly left a trace.

At the recent Manchester meeting of the "British Association," Mr. J. H. Greathead read a paper on the "City of London and Southwark Subway." From this we learn that the subway will be three miles long. The up and down lines will be in separate tunnels, placed at a sufficient depth to avoid all interference with sewers, etc. Except where the lines pass under the river and wharves, they will run under the streets their entire length. The cable system of traction will be used. The total cost from beginning to end, including land, buildings, stations, equipment, etc., he estimates, will not exceed \$1,000,000 per mile, a small fraction of the cost of the present underground London railways.

THE little railroad between Bienne and Macolin, in Switzerland, is described in the last number of the *Génie Civil*. The road was opened for traffic on the first of last June. Its total length is 1,645 metres, in which length it rises 450 metres. The building of the line necessitated important engineering problems. It crosses two iron viaducts, one 90 metres and the other 120 metres long. A train consists of two cars each, and three trains can be run an hour. Each car is supplied with four distinct safety appliances. The traction is by an endless cable. The construction of the road, not including land, was done under forfeit at a cost of 410,000 francs.

A WRITER for the *Architect* (English) holds that the testing of building stone is the only important one to which chemistry can be put directly in connection with building, and concludes that since it is possible without the aid of chemistry to select a durable building stone, while chemical experiments for this purpose must be supplemented by observation and practical experience, that it is inadvisable to add the study of chemistry to the course of the already overburdened student of architecture, especially since the services of an expert can always be obtained in special and important cases.

THE lead covering of the *fiche* of the Cathedral of Notre Dame, of Paris, has been seriously deteriorated by the action of the acetic acid developed by the rotting of the oak frame upon which the ornamented lead covering is laid.

THE Baltimore Society, aided by an appropriation from the institute, instituted an exploring expedition in Magna Græcia under the direction of Mr. Joseph Thacher Clarke, with whom was associated Dr. Alfred Emerson. The principal work of this expedition was on the site of ancient Croton. Unfortunately, the work here has been suspended on account of legal complications with the Italian Government. Mr. Clarke is now engaged upon the completion of his report on the investigations at Assos. The institute proposes during the coming year to limit its efforts to securing a permanent fund for the endowment of the school at Athens.

DOMESTIC ENGINEERING, ETC., IN THE
EQUITABLE LIFE INSURANCE BUILD-
ING, NEW YORK CITY.

No. V.*

(Continued from page 619.)

THE ELEVATORS.

THE elevating apparatus or machine illustrated by Figs. 5 and 6 has a number of new features.

The cylinder A is 33 inches diameter; the travel of the piston and also of the rope sheaves B is 14 feet; the piston is fitted with flexible leather rings of L-shaped section which are expanded outwardly by the pressure of the water. The sheaves C, five in number, are stationary as far as longitudinal movement is concerned. The sheaves B, also five in number, are supported on the shaft of the piston-rod cross-head F, therefore move out and in, from and toward the cylinder A, at every movement of the car. The cross-head with its sheaves is guided and sustained in its travel by the rails G, which are made of heavy T-section cast iron, planed smooth. A lip-piece is bolted to the cross-head and extends down under the outer member of the T-rail, serving to keep the cross-head from rising.

The piston-rod is composed of extra heavy wrought-iron pipe. A scraper is provided in front of the cross-head, angled so as to shove off any tools or other obstructions carelessly left on the rails. On the piston-rod is bolted a projecting arm (not shown), which about midway of its travel engages a small carriage placed on the rails and carrying a cross-shaft on which are strung loose pulleys, their office being to bear up the horizontal part of the rope that would otherwise sag when the water is turned off and cause the dancing motion so often observed in cars when suddenly stopped by the operator. The sheaves, both stationary and traveling, are 44 inches diameter, broad on the face and grooved to receive four $\frac{3}{4}$ -inch ropes. They run on steel shafts, and are each bushed with composition metal and provided with special oil-cups. The small bearing or carrying rollers H, on the ends of the

FIGURE 6.

FIGURE 5.

cross-head shaft are 8 inches diameter and turned smooth so that the cross-head may work out and in without jar.

The motion and velocity of the elevator is regulated by a horizontal piston-valve J having a longitudinal motion, operated by a rack and pinion, an endless wire rope $\frac{1}{2}$ inch diameter passing through the car and up over a pair of small sheaves at the top of the well, thence down the well and over a small guide-sheave to 30-inch sheave keyed on the rack-pinion shaft. This furnishes the means of stopping and starting from within the car at any part of

its travel. The cut of the elevator shown in Fig. 5 is a general view, hence the adoption of guide-sheaves and 30-inch sheave and rope, etc., suitable to Equitable Building is not shown. Between this main valve and the cylinder is placed an automatic stop-valve I, for the purpose of partially shutting off the supply of water and insuring an easy and gradual stopping of the car when it has reached a point about six feet from the limit of travel, both up and down. An arm K from the cross-head engaging a stop L, fastened on rod M, is the means by which this is accomplished, the rod being returned to normal position by apparatus N. In case of accident to the main valve or to the operator in the car this auxiliary valve completely stops the run of the piston when the car has actually reached the top or bottom landing, preventing the smash-

ing of the car or cylinder heads. An air-valve opening inwardly is furnished on the body of the regular valve-chamber, its object being to admit air and prevent a vacuum forming when the motion is reversed to discharge water. The discharge-pipe is furnished with a globe-valve at a point near the cylinder for the purpose of regulating the downward speed of the car. The weight of the car is borne by four No. 17 Roebling wire ropes, each taking a fourth of the weight, through the intervention of the equalizing levers P, Fig. 6. This composite rope passes around five multiplying sheaves, making the proportion of car travel to piston speed as ten to one.

The regular working load of the elevators is 3,500 pounds, but by an arrangement of direct pumping into the elevator cylinders Nos. 4 and 9, is made to raise loads of 8,000

*No. I. of these articles, containing the first installment of Sketches of Plumbing, appeared in our issue of October 8; No. II., General Description of Building and Plant, October 15; No. III., Details of Pumps and Boilers, October 22; No. IV., Smoke-Stack and Passenger-Elevator Water-Supply, October 29.

pounds, such as safes and heavy furniture. For this purpose a pressure of 200 to 240 pounds per square inch can be furnished if necessary. The small duplex pump shown at F in the cellar plan is connected for this service as shown on elevator No. 9.

THE CAR.

The frame-work upon which the car proper rests, shown in Fig. 6, contains novel features. The bottom consists of a frame-work of 4x4-inch ash supported by two 4-inch channel-beams *a a*, to which are bolted the cast-steel guide-shoes, *b b*, fitted with an automatic safety attachment, which is operated by the counterweight of the car. The usual overhead cross-beam consists of two wrought-iron plates, *m*, 8x½-inch section. The connection between the cross-beams and bottom is formed by eight bolts—viz.: one, ¾-inch diameter, running to each corner of the frame-work; two, ½-inch diameter, running to cross-bars on each side of the car placed underneath the channel-beams. Guide-shoes are bolted to the cross-beam, which, for purposes of steadiness, are provided with adjustable gibs.

The two bars that compose the cross-beam are held together at the centre by a casting, *n* of strong construction, made of composition metal; to this casting is fastened a system of whiffletrees that insure an equal strain being put upon each member of the composite hoisting rope; if from any cause one member of the rope lengthens more the others, a deflection of the cross-bar or whiffletree gives notice of such change, while the whiffletree, as a whole, is held in the upper part of the slot C, so long as the load of the car is sustained by the hoisting-rope. The counterweights of the car are suspended through the levers, *d d*, in such a manner as to drag the whiffletree to the bottom of the slot the moment the rope breaks. Such action brings the lever *f*, into play, and by means of the connecting-rod *g* the shafts *h h* are revolved sufficiently to bring the teeth of the spiral-surfaced segment *j* against the sides of the guide-rails *k k* with great force, thus holding the car from falling down the well.

FIG. 7.

The pin *p* carries two links shown in dotted lines; these links are connected at their lower ends by the pin *p*; resting on top of this pin are the long ends of the levers *d d*, while to their short ends are fastened the counterweight ropes *S S*. One end of the lever *f* passes under the same pin, but in its normal position does not touch it; the other end is connected to the lever *f*, by the connecting rod *g g*. Any downward action of the pin *p* through slot C—caused by the breaking of the hoisting rope, etc.—gives instantaneous movement to these levers to produce stoppage of the car, the motive power being the weight of the counterweights. A working car speed of 500 feet per minute is attainable, but the average working speed adopted throughout the building is 350 feet.

THE WELL (FIG. 6).

The several wells or shafts in which the elevators work were planned to accommodate two elevators each, so that a central guide-post serves for both, making three guide-posts in each well.

The central posts, 8x10 inches, are made of four pieces of white pine, 2x10 inches, nailed together; this has the advantage of bringing the joints at different places and providing against warping. The guide-rail is made of maple wood in pieces four feet long, tongued and grooved at their ends, and fastened by strong screws to the guide-posts. Coincident with each landing are placed I-beams, *u*, directly across the centre of the well around which the central post is built. This arrangement is shown in Fig. 7. The width of the beam being eight inches admits the outer planks of the post to pass without cutting; the space between these and the body of the I-beams is filled up by blocks bolted into place and made flush with the edges of the beam, thus providing a place for receiving the points of the screws that hold on the outer portion. The two outer guide-posts are built into the wall of the well and are held in place by means of bolts that pass through the posts and are held in the headed slots in cast-iron "bricks" built into the wall at suitable places.

The diameter of the hoisting-rope sheaves, placed at the top of the well and shown in Fig. 6 is forty-five inches. The method of mounting them in place is fully shown in the cut. The I-beams shown are 15-inch; 150 pounds per yard. The shafts are of steel and run in babbited boxes provided with good oiling arrangements. One sheave of the four is keyed to the shaft, while the others are loose to allow for irregularities of stretch in the rope. The diameter of the counterweight sheaves is forty-eight inches, so as to bring the counterweights as close to the wall as they will work. The counterweight is made of cast iron in several pieces and bolted together in place. It is made heavy enough to almost balance the weight of the car and arranged to receive additional weight while in place if found to be necessary. The counterweight rails are at the back of the car-well opposite the entrance doors.

The walls of the well are covered with white-glazed tile. The contractors for the elevators and appurtenances found it advantageous to have a man on the ground to watch the progress of the wells and place the cast-iron bricks with the tee-slots in proper places, and also to see that the I-beams across the well-holes were placed above each other in an exactly vertical line.

(TO BE CONTINUED.)

THE ATTEMPT TO DECEIVE A CINCINNATI BUILDING INSPECTOR.

It has been suggested that we make our account of the attempt to cheat the plumbing inspector of Cincinnati, published in our issue of October 15, more intelligible by a sketch. The accompanying has therefore been prepared to show what the plumber did. It will be remembered the pipes were to be subjected to the water test, and plugs were found in them so that the water could not reach beyond that point, hence the one or two joints above the plugs were all that it was thought necessary to make tight.

THE WINTER'S WORK OF THE NEW TRADE SCHOOLS.

The excellent work of these admirable schools, founded and maintained by Richard T. Auchmuty, Esq., of this city, is now well known to our readers. The instruction is entirely practical in character and adapted to fitting young men to make a living in several of the trades. The seventh season began on October 26. We note below the courses of study.

In Plumbing there will be a night class and a day class, and the instruction will be both practical in the shop and theoretical by lectures on the theory and practice of the art. The day class will take gas-fitting as well as plumbing.

In House-Painting the evening class will study preparing woods for painting, applying the different coats, flattening, polish white, use of various oils and dryers, and study of the harmony of colors. There will be also a day class in House and Sign-Painting.

In Fresco-Painting, instruction, in the evening, leads from the making of lines and shading to elaborate designs. Some of the designs of scholars of previous seasons have been exhibited at the American Institute Fair.

In the Bricklaying Class evening instruction is given in building walls, piers, arches, flues, fire-places, setting sills, corbelling, etc. Instruction is also given in laying face-brick.

The Plastering Class, beginning November 30 and ending March 2, studies scratch coating, brown coating, hard finishing, mitering, etc.

In Stone-Cutting there will be both day and evening classes, in plain and ornamental cutting.

The Carpentry Class will have instruction in carpenters' and joiners' work in the evening. There will also be given instruction in Wood Carving, with evening classes.

The class in Blacksmith's Work will study forgings and vise-work, with instruction in the management of fires, drawing down, welding, riveting, etc., and filing, fitting tongues and grooves, and other handiwork.

Under direction of the Merchant Tailors' Society of the City of New York instruction will be given in all branches of the tailoring trade.

Information in addition to what is given can be obtained by addressing the New York Trade Schools, Sixty-seventh and Sixty-eighth Streets, New York City.

A FIRE FROM GASOLINE IN A VAULT.

Our Milwaukee correspondent writes: "Fire nearly destroyed Jacob Winkler's plumbing and gas-fitting store. A boy went to a gasoline barrel under the sidewalk and lit the gas. The vapors arising from the gasoline caught fire and a fierce conflagration resulted. To make matters worse the lead connections at the meter melted and the escaping gas helped the fire. It was finally put out by shoveling loads of sand in the coal hole. Chief Foley thinks that all buildings should have a box to the sidewalk to shut off gas in case of fire."

SALARIES OF HOUSE-DRAINAGE INSPECTORS.

OFFICE OF THE BOARD OF HEALTH,
PHILADELPHIA, October 24, 1887.

SIR: Please inform me through your valuable paper if you have the data of what the different cities pay their inspectors of house-drainage and ventilation. By so doing you will confer a favor.

Yours respectfully,

INSPECTOR.

P. S.—Philadelphia pays one thousand dollars.

[In New York the inspectors of plumbing and drainage receive \$1,260 per annum, with the exception of two special experts who receive \$1,600. Each of said inspectors is required, in addition to plumbing and drainage, to inspect tenement-houses as to light and ventilation. The average number of houses in each inspection district is about 300. In the opinion of those well able to judge, the amount of salary is inadequate for the service rendered and the skill necessary to properly discharge the duties of the position.]

A WOOD-BURNING HEATING-BOILER WANTED.

FORT SHERMAN, IDAHO, October 18, 1887.

SIR: I want a wood-burning boiler for steam-heating a house of ten to twelve rooms, the same boiler to supply hot-water for bath-room. All the boilers advertised are either for hard coal, soft coal, or coke. These are not procurable here except at great expense. I request the benefit of your advice as to kind of boiler and the necessary arrangement of the system. The following is a rough sketch of first and second floor plans.

Two rooms in attic, cellar under whole house. Wood available, yellow pine. House faces south.

Please give this subject any attention you can and reply in THE ENGINEERING AND BUILDING RECORD as answer to correspondent. Respectfully, J. A. L.

[We cannot recommend the burning of wood for house-heating under a steam-boiler. It is next to impossible to control combustion and the pressure of the steam automatically and safely when wood is the fuel. If you wish to try the experiment use a pipe-boiler of some kind, such as the Nason & Blake, that has a long furnace, and see that the brick-setting and doors are absolutely air-tight. The latter can be planed and fitted, but to make the former tight two walls must be built: the first one, say eight inches thick, thoroughly coated with tar or bitumen; then one of four inches built against it. Opening the fire-door of a wood-fed boiler will not check the steam, hence you must depend entirely on the lower door. In other respects fit your apparatus as you would for coal.]

MAKING VERSUS BUYING SOLDER.

SIR: Would you kindly devote a small space in your paper to inform me, a constant subscriber, of the method of making solder from old joints, and also if it is any saving from buying from manufactories, and oblige,

JOHN BUTLER.

[We believe it cheaper for a plumber to sell the old joints to solder manufacturers and buy solder than to try to make it—at least in cities where there is market for the joints. The trouble in making solder from old joints is that the purity of the lead from which the lead pipe was made cannot be relied on, old lead often being used in manufacturing pipe. Manufacturers of solder on a large scale, however, have facilities for refining the metal they use that individuals do not possess.]

ON VENTILATING SOIL-PIPES.

BOSTON, October 21, 1887.

SIR: Suppose the basement drains in a building to be laid out as shown on accompanying diagram, 4-inch soil-pipes running down from closets on floors above at points *s s s*. A running trap is located at *t*. Now, if an air-pipe were run from drain at point *a*, outside trap *t*, up through roof, would not this obviate the necessity of carrying each vertical run of soil-pipes *s* through the roof? What advantages, if any, would the latter plan offer over that shown in the diagram, and if the plan shown in diagram is feasible, how large should the vertical air-pipe be?

INQUIRER.

[The pipe to run through roof from point *a* would be of no use to protect the traps on the branches *s s s*. If the pipes at these branches did not extend through roof they would be practically "dead ends"—that is, there could be no movement of air through them, and the seals of the traps could not be maintained. The fixtures should be placed on short branches from a vertical pipe which extends through the roof. The pipe at *a* may be dispensed with as a needless expense.]

A CASE OF FRACTURE OF TERRA-COTTA.

WE received the following inquiry from an architect of N. Y. City, which touched a matter of sufficient interest to justify careful investigation:

"Can you or some of your contributors inform me of the probable cause of the destruction of the terra-cotta work on the east front of the Produce Exchange in this city? It is especially noticeable in the voussours of the third-story arches, where pieces having an average area of some two square feet have seemingly scaled off, exposing the core and backing.

"Yours respectfully, ARCHITECT."

A representative of this journal has investigated the matter and reports as follows:

The abutting faces of the voussours, or arch blocks, are concave, a lip about an inch wide projecting all around the face nearly one-half an inch, giving a mortar-joint one inch thick or more at the centre, and a quarter of an inch or less between the lips. Mr. Armstrong, of Moran & Armstrong, who did the mason-work on the building, stated that this was nearly the last portion of the work completed, and that it was done in unfavorable weather, and while the terra-cotta may have been defective, he is inclined, for the above reasons, to believe that the failure is due mainly to imperfect filling of the joints, which, permitting undue pressure on the projecting lips, caused the fractures. Mr. George B. Post, the architect, says: "An examination shows conclusively that the main trouble lies in the fact that the blocks were not thoroughly filled with concrete before they were set. It may be in some cases that the terra-cotta was not perfect, but that is a matter which it is difficult to determine, even by close inspection after it is broken."

These statements, though assigning somewhat different causes for the trouble, are not contradictory, but mutually corroborative, as the ultimate cause is probably the same in each—viz., hurried work toward the close of a large job and bad weather.

The superficial scaling, which appears in some places, is due, according to the manufacturers, to an attempt on their part to improve the color of the blocks by coating the surface before burning with a wash of finer clay of better appearance, but not strong enough to form the body of the blocks. This has in some cases since peeled off, but does not in the least affect the strength of the work.

The lessons from this incident, however, are obvious. Terra-cotta requires careful filling and careful bedding; if either is deficient there will be trouble, and, in filling the blocks, it should be remembered that some cements expand in setting, and hence are liable to burst the terra-cotta.

PROTECTING WALLS OF BATH CELLS.

COLORADO SPRINGS, COL., October 19, 1887.

SIR: Can you inform me what kind of paint to use on wooden partition walls for bath-cells, where the paint or varnish cover is exposed to the hot vapor of water containing sulphurous and iron salts?

Or can you recommend any other kind of finish for such walls? I have been consulted in regard to the wall finish for a projected sanitary plant at Glenwood Springs and have recommended for floor finish "Seyssel" or "Neufchatel Rock Asphalt" and hard brick partitions with soapstone finish, but the management prefers at the latest date wooden partitions.

Any information you may favor me with will be duly appreciated by

TYRO.

[If wooden partitions are used we know of no paint or varnish which will give satisfactory results. Hard tiles or enameled bricks have been used for walls of steam baths with good results. Soapstone finish for walls has not been tried under such circumstances, but it would probably do well.]

IF "Old Subscriber," who inquired about dampness on inside walls, will give his name and address so that we can obtain further particulars, we may be able to answer his query.

PLUMBING IN PHILADELPHIA PUBLIC BUILDINGS.

(Special Correspondence.)

THE Board of Directors of the Master Plumbers' Association has elected William M. Wright president of the association to fill the vacancy caused by the resignation of Mr. W. E. Lindsley.

The work of fitting up the third floor of the new public building of this city is now being pushed rapidly forward and it will be shortly ready for occupancy.

A novel feature of the fittings of this floor is the use of polished granite for the back and sides of the urinals. This is said by one of the architects to be among the first used for that purpose in the country.

The architects have also discarded the use of traps on the urinals and water-closets of this floor and are ventilating the water-closets into a large chimney.

THE *Chronique Industrielle* contains an interesting account of the first electric-power vessel constructed in France. It is propelled by a dynamo-electric machine, the invention of Captain Krebs.

AMERICAN SOCIETY OF CIVIL ENGINEERS.

A MEETING of the society was held Wednesday evening, November 2, at which several resolutions for making changes in the constitution were presented, and the following were read by the Secretary:

At a meeting of the society, held at the Hotel Kaaterskill July 6, 1887, a resolution was adopted that it is expedient to create a grade of students of the society, said grade to consist of young men over eighteen and under twenty-five years of age.

Also the following: That a committee of five be appointed to consider and report at the meeting on the first Wednesday of October, 1887, the advisability of adding a new grade of membership.

A committee was then appointed by the President.

At a meeting of the society, October 5, 1887, the following report was received from the majority of the committee: *President and Members of the American Society of Civil Engineers.*

Your committee appointed under a resolution adopted at the meeting of the society held at Hotel Kaaterskill, July 6, 1887, "To consider and report at the meeting on the first Wednesday of October, 1887, the advisability of adding a new grade of membership to be called 'Students,' and what alterations of the Constitution and By-Laws will be required to establish such a grade," respectfully reports: That we have prepared and submit herewith amendments to the Constitution, and a resolution fixing the dues to be paid by those who enter the proposed grade.

In considering the advisability of creating this new grade of membership, we have taken into full account the only objection that has been raised to such action—that it would lower the standard of the society. If there be danger of such result, then your committee would certainly report that the proposed action is not advisable. If membership of the society is to remain as now established, then to add a lower grade would, in a certain sense, lower the average of the society, and so afford some ground for the objection. If, on the other hand, the creation of a new grade is made the occasion of an advance in the standard of qualification for the higher grades, then the spirit of the objection is an argument for the proposed action. Another consideration influences your committee, which is, that we find scant room for a grade of students below the requirements for the present class of Junior. We therefore say, decidedly, that if the society is unwilling to raise the standard of qualification required for membership in grades now established, then it is inexpedient and not advisable to create the proposed grade of students.

But if the society is ready to raise the standard for all grades, then we say the creation of the proposed grade of students is expedient and advisable.

To test the disposition of the society, and with confidence that it is ready for a step in advance, we report in favor of the adoption of the accompanying amendments and resolution. Robert E. McMath, Chairman; Robert H. Thurston, W. H. Paine, Robert Moore.

The active members of the society shall be divided into three classes, to be styled respectively members, associate members, and associates.

Associate members shall have all the rights and privileges of members excepting the right to hold office or to vote upon admission to membership. Associates shall have all the rights and privileges of members excepting the right to hold office or to vote.

There shall also be a preparatory grade, to be designated Students of the Society, who shall have the right to attend all meetings not strictly devoted to business and to use the library and rooms of the society under such regulations as the Board of Direction may adopt. They shall have by right the Transactions of the Society, and the privilege of presenting papers and written discussions.

Members of the Class previously styled Juniors shall, after March 7, 1888, be classed as Associate Members.

A Member shall be a Civil, Military, Mining or Mechanical Engineer, not less than thirty years of age, who has been in active practice as such for at least ten years, or has graduated at a School of Engineering after a full course of study and been in practice seven years, and who continues in actual practice at the time of application for membership, and who has had responsible charge of work as Chief, Resident, or Superintending Engineer for at least two years, not as a skillful workman merely, but as one qualified to design as well as to direct engineering works.

An Associate Member shall be one over twenty-four years who has had actual practice in some of the branches of Civil, Military, Mining or Mechanical Engineering for at least five years; or, if a graduate of a school of engineering, after a full course of study, who has practiced at least two years.

An Associate shall be one over twenty-five years of age, who is a manager of a railroad, canal or other public work; a geologist, chemist or mathematician; a proprietor or manager of a mine or metallurgical works; an architect or a manufacturer; or one who, from his scientific acquirements or practical experience, has attained eminence in his special pursuit, qualifying him to co-operate with engineers in the advancement of professional knowledge; but shall not himself be practicing as an engineer.

A Student shall be one not less than 18 years of age, who is engaged in the study of engineering with the intent to become an engineer and who has pursued that study at a technical school not less than one year, or who shall have been engaged in the study and practice of engineering under a competent engineer for not less than two years. A student shall not remain in that grade for more than seven years; if not elected to a higher grade his connection with the society shall terminate at the end of seven years.

In the event of the society adopting amendments to the Constitution creating the grades of associate member and students of the society, that the entrance fee and annual dues of associate members shall be the same as established for associates; for students no entrance fee shall be required, and the annual dues shall be, for resident students, ten dollars, and for non-resident students, six dollars per annum.

Report of committee stating reasons for the several changes and alterations in the constitution that are proposed:

Designation of Classes.—It will be observed that the designation of the several classes is similar to that of the Institution of Civil Engineers, and, we may say, also to that adopted by the recently organized "Canadian Society of Civil Engineers." Uniformity of designation and in the standard of qualification for the several grades ought to be aimed at by the leading engineer societies; we think these designations appropriate.

Definition of Rights.—We think it well to give associate members superior rights to associates, but materially less than members. The rights of students are secured.

Junior classes abolished; its members transferred to associate members.

This change will work no hardship, except to those who are enamored with the lower grade. The society should put pressure on such to move along. Some of the recent admissions to the junior class will get into associate membership under age, but this is no hardship to them.

Qualifications for Membership.—The age specified, 30, is thought by your committee to be a fair compromise between various suggestions, mostly higher.

The thought is, that admission to full membership is a final endorsement by the society of the man, and that his character should be fixed by experience under the test of actual life for several years. Membership will thus have a meaning and value, and its attainment will be an object to be sought. In the experience qualification the aim is to give decided preference to those who enter the profession with the advantage of a technical education. The extension of experience from 7 to 10 years and responsible position from 1 to 2 years is an intended advance in the required qualifications.

Qualifications of Associate Members.—This is a decided advance in age and experience over that required for the present class of junior.

Qualifications of Associates.—Except the requirement of 25 years, the qualification for this class is unchanged.

Qualifications of Students.—A decided advantage is allowed the student from a technical school, since there is now little excuse for any young man who would enter the profession without the advantage of a technical education. We have thought it well to fix a time, instead of age, limit to continue in this grade, otherwise those who graduate young and immature would have the advantage of older students. The grade of associate member should be fairly open to the student before his studentship terminates.

Nomination and Election of Students.—But one endorser is required, and he may be of any grade higher than student, because young men cannot be well known except

by those with whom they have been associated in the capacity of pupil or subordinate.

Their election is left to the Board of Direction to emphasize the fact that students are not members of the society, but are probationers, and subject to the Board of Direction for admonition and discipline.

Mr. Fred. Brooks, member of the committee, presented proposed amendments differing from those presented by the majority of the committee and retaining the name of junior.

A resolution was presented relative to admitting engineers not resident in North America who may not be personally known to five members, and may be endorsed by five members of Board of Directors who shall secure evidence sufficient to show that the candidate is worthy. This was signed by Theodore Cooper, W. R. Hutton, A. D. Foote, P. J. Sosa, J. P. Davis.

An amendment was proposed relative to balloting for members, which required that when a candidate had been rejected, and the Board of Directors should receive written application from eight members stating reasons therefor, and if deemed sufficient another ballot to be ordered. This ballot to be an open one and five negatives to exclude. Signed by Theodore Cooper, F. A. Calkins, D. McN. Stauffer, L. L. Buck, J. P. Davis.

The following amendment was also introduced, that members shall be elected by a two-thirds vote of the Board of Direction, which was signed by J. J. R. Croes, G. S. Greene, Jr., D. McN. Stauffer, O. H. Nichols, C. W. Hunt.

After the above were presented the result of ballot for members was announced, and the following were elected as members in their several classes:

For Members.—George Earl Church, Civil and Consulting Engineer, London, Eng.; Henry Stevens Haines, Chief Engineer and General Manager Savannah, Florida and Western Railroad, and Chief Engineer and General Manager "Plant System," S. F. & W. R. R., Savannah, Geo.; David Carlisle Humphreys, Adjunct Professor of Applied Mathematics in Washington and Lee University, and U. S. Assistant Engineer with Missouri River Commission, St. Louis, Mo.; William Datus Kelley, Jr., Special Assistant Engineer on New Croton Aqueduct, Tarrytown, N. Y.; Rowland Robinson Minturn, Assistant Division and Locating Engineer, Chicago, Milwaukee and St. Paul Railway, Milwaukee, Wis.; James Moylan, engaged in general practice of Civil Engineering, New York City; Cornelius Palmer, Superintendent of Bridges and Buildings Chicago and Northwestern Railway, Escanaba, Mich.; William Barclay Parsons, Consulting Engineer, New York City; Edward Fesser Playle, Assistant Engineer in charge of Shafts Nos. 21, 22, and 23 New Croton Aqueduct, Morris Dock, New York City; Albert Fowler Robinson, Bridge Engineer, Chicago, Burlington and Northern Railroad, St. Paul, Minn.; Orlando Belina Wheeler, U. S. Assistant Engineer in charge Triangulation party under Missouri River Commission, St. Louis, Mo.

For Associate.—Arthur James Moxham, President Johnson Steel Street Rail Co., Johnstown, Pa.

For Juniors.—Archie McLean Hawks, Assistant Engineer Randolph Bridge, Chicago, Milwaukee and St. Paul Railway, St. Louis, Mo.; Downing Vaux, with Department Public Works, in Bureau of Sewers, New York City.

REPLACING STONE TOWERS OF THE NIAGARA RAILWAY SUSPENSION BRIDGE WITH IRON TOWERS.

A paper was presented by L. L. Buck, Mem. Am. Soc. C. E., on "Replacing the Stone Towers of the Niagara Railway Suspension Bridge with Iron Towers." This bridge was completed in 1855, and the writer states that the stone towers rested on the rock which forms the banks of the gorge spanned by the bridge. On the New York side the towers were about ninety feet high and on the Canadian side eighty feet high. The base of the towers was very large, composed of rock-faced ashler, extending nearly to the level of the upper chords. The towers on each side of the river were double, and the portion above the base was fifteen feet square at base and eight feet square at top.

The stone used was limestone, quarried near the site of the bridge. A few of the first stones laid at the bottom of the towers were from the surface, and all remaining stones were taken from a stratum below, and did not bear exposure to the weather. This defect developed some time after completion, and irregular-shaped pieces would become detached, and cracks appeared in various parts of the surface. Painting was resorted to as a preventative and continued at intervals as long as the towers were retained.

While work of rebuilding the suspended superstructure was in progress in 1880 the writer noticed that the most defective portions of the towers were those located one-third of the distance from the level of the railway floor to the top, and the disintegration decreased as the distance

above and below this point increased. This could only be accounted for by supposing that the towers were being subjected to a considerable bending stress, which would be greatest at this point, that opened the joints and admitted water, coupled with increased pressure at the surface, and bad character of the stones would partly account for it.

The cause of this bending stress was the elongation and contraction of the cables between the towers and the anchorage, produced by live-load stress and changes of temperature. The maximum movement at the top of the tower produced by the live load is about $\frac{1}{4}$ of an inch, while that produced by temperature between extremes is a little over two inches. As these two forces act in concert only at the maximum temperature, it is evident that the greatest movement of the saddle at maximum temperature would be about $1\frac{1}{4}$ inches from its normal position and toward the river, while in the opposite direction it would move from the normal position to that at minimum temperature about one inch. In 1880 the greatest movement of the saddles with respect to the bed-plate was $\frac{1}{8}$ of an inch, and the repairs to suspended superstructure was completed at this time.

The only plan for repairing the towers that promised success was the cutting away of defective portions of the stones to various depths, or till the sounder portions within were reached, and then reface the towers with new stones, thoroughly anchored to the interior portion, and cement and grout all interstices. This refacing was completed in the fall of 1883, the last tower repaired being on the Canadian side. On returning from the West late in the fall cracks of a serious nature were found in the last tower repaired. One crack started at the middle of the top of the south side, and the other at the middle of the top on the westerly side both extended downward, gradually approaching the south-west corner, where they met at a point above the railway floor about one-third the height of the tower above the floor.

In September, 1885, the north tower on New York side was apparently in fair condition. The south tower on the same side had opened some of its joints slightly, and two or three of the new facing stones were slightly cracked. On the Canadian side the south tower had some open joints, and several new stones were cracked. A serious crack also started in the old stones on the east face, beginning about twelve inches from the north-east corner, thence extending upward and toward the middle of the face through three courses. As the old stones were larger than the new this was more serious.

The north tower was in a far worse condition than any of the others, as many of the joints of the new face stones opened, but on the south and west faces many of the stones were so badly cracked that some appeared ready to fall out.

At this time motion of the saddles on the rollers had nearly ceased. All of the rollers on top of one tower only covered an area of $3\frac{1}{4}$ inches by 4 feet 7 inches, equal to 17.18 square feet. The bed-plate could not effectually increase the area of distribution of the weight to more than 25 square feet. The maximum weight of about 900 tons resting on the rollers would cause a pressure of 35 tons per square foot on the masonry. The trouble proved of such a serious character that plans were prepared for replacing the stone tower with iron, of which the following is a brief description. Each iron tower is made up of four wrought-iron columns braced transversely and longitudinally by wrought-iron struts and rods. Each column is supported by a limestone pedestal resting on the rock and capped with granite. The outer portions of the old bases were cut away to make room for the new pedestal. The tops of each pair of columns were connected by a heavy web-plate secured to each web of the columns by angles and rivets. On the caps of the two pairs of columns rests the main bed, built up of wrought-iron plates and angles. It is in plan 9 feet 2 inches by 5 feet 3 inches, and weighs $9\frac{1}{2}$ tons. On this is placed steel plates with long side parallel with direction of cable, on which 18 steel rollers are laid each 4 inches in diameter, covered by a cast-iron plate 7 feet by 2 feet 4 inches by 18 inches in height.

The transferring-apparatus consisted of four cast-iron columns, two transverse and two longitudinal girders, six 125-ton hydraulic-jacks, wrought iron Shim plates, and No. 8 cast-steel wire.

The writer then gave a very interesting detailed description of the process adopted to erect the iron towers and

transfer the cables to them, and removal of the stone in the old towers.

The total weight raised by the six jacks was about 650 tons, each jack being operated by two men. In cutting away the faces of the old towers at the top, the stones were found to be cracked through vertically. In removing the three upper courses the interior stones were found to be sadly shattered in every direction. While the stones were thus broken up, the cement gave indications of having been excellent.

The old rollers were found imbedded in cement and iron rust; the spaces between them and between their ends and ribs of the bed-plates being filled with this cement, which had become so firm that a chisel-bar was required in extracting the rollers. Each roller was in a trough from which no water escaped except by evaporation. While this cement had originally allowed the rollers some motion, the corrosion caused by the water operating upon the iron surface kept clean by the heavy rolling pressure had flattened the bottom sides of the rollers more than one-thirty-second of an inch, and produced depressions in the bed-plate to the depth of three-thirty-seconds of an inch.

The removal of the old stone was a tedious process, and the writer did not know of any whole stones being found.

THE MINNEAPOLIS ENGINEERS' CLUB

At the last meeting of the club Horace E. Horton, of Rochester, was elected to membership, and the names of Peter Howe, John Brawley, and George W. Ferris were proposed. Mr. James Rigby read a paper on "Gas and Light." He showed how vast had been the progress in artificial lighting, and yet how little understood the subject is at present. He had with him some interesting drawings. The club will hold meetings semi-monthly during the winter.

THE NEW YORK ARCHITECTURAL LEAGUE

At the last meeting of the New York Architectural League, the following gentlemen were elected members: A. F. D'Oench, Superintendent of the Building Department, Mr. Bright, A. E. Barlow; non-resident members, J. W. Root, of Chicago; H. C. Burdette, of Buffalo.

THE NEW CHICAGO PUMPING-ENGINES.

The Commissioner of Public Works has received the following report from Committee of Experts on trial of the new Gaskill engine:

CHICAGO, ILL., October 29, 1887.

Hon. George B. Swift, Commissioner of Public Works, Chicago, Ill.

SIR: The undersigned, the committee appointed by you to make a trial of the new Gaskill pumping engines now in operation at the North Side pumping station, beg leave to submit the following report of the results obtained.

A trial of each set of machinery was made, beginning on Monday, the 24th inst. with the west pair of engines, the trials being of twenty-four hours duration each, that period having been adjudged by the committee sufficient to settle the questions referred to it by the city. A supplementary trial was also made of the engines first tested, to determine the efficiency of the boilers and the distribution of heat in the engines. The data obtained and the calculated results will be submitted in full detail later.

The conclusions of your committee are as follows:

The contract made with the Holly Manufacturing Co., of Lockport, N. Y., the builders of the engines, binds them to furnish two sets of pumping machinery, each capable of delivering 12,000,000 gallons of water per day of twenty-four hours, against a head of one hundred and fifty feet, the piston speed not exceeding one hundred and twenty feet per minute, and to develop a duty of not less than 95,000,000 foot pounds per 100 pounds of coal burned in the boilers, no allowance for ashes or any other wastes being made.

The contractors are also called upon to furnish engines of good design, construction, and material.

Your committee find upon test that the engines furnished by these contractors are of good design, of excellent workmanship, and, as far as they have been able to judge by inspection, of the best of material. This committee are also able to certify that the stipulated capacity has been secured and that the duty actually obtained is considerably above that demanded, exceeding 100,000,000 foot pounds of work done per 100 pounds of coal consumed.

Very respectfully,

R. H. THURSTON, J. S. COON, JAMES N. WARRINGTON, Committee.

THE LEVEL OF THE NEWPORT SEWER.

The committee of experts appointed to find out whether Newport's main sewer ran up hill anywhere have been able to report a very satisfactory negative. The sewer is at all points either level or inclined toward its outlet.

THE HARLEM RIVER IMPROVEMENT.

The work on the Harlem River improvement at Two Hundred and Twentieth Street, for which proposals are invited in our advertising columns, and for which Congress appropriated \$400,000 at its last session, is but a small portion of the whole work, which contemplates eventually the formation of a navigable channel from 350 to 400 feet wide, and from 15 to 18 feet deep, from the East River to the Hudson River, by the way of Harlem River and Spuyten Duyvil Creek.

The chief work will consist of a rock cut through Dyckman's Meadow connecting the Harlem River and Spuyten Duyvil Creek, and an earth cut through the meadow south of the rolling mill and Johnson's foundry on Spuyten Duyvil Creek, with such protection for the sides of the cut as may be needed to prevent the banks from washing away, but owing to the smallness of the appropriation, the present work will be confined to a portion of the rock cut.

The material to be excavated in the cut is dolomite, a limestone known in that neighborhood as Westchester marble, with a covering of mud, earth, sand, or loose rock, varying in depth from about 10 feet to nothing.

The present elevation of the ground varies from about 6 feet to 63 feet above the plane of mean low water at that point.

The work must be commenced within twenty days after the contract is signed, and completed by September 30, 1888.

THE NEW PENSION BUILDING.

The report of General M. C. Meigs, the architect of the new Pension Building, dated September 3, 1887, contains some interesting figures. The ground plan of this building includes 80,000 square feet, its floor areas 188,258 square feet, and the contents of the outer skin of the walls 8,211,502 cubic feet. There were 78,800 tons of material used in its construction, including 15,500,000 brick. Its cost per cubic foot of space was 10 $\frac{3}{4}$ cents. The space heated and ventilated, excluding the cellar, is 6,170,200 cubic feet. The ratios of heating surface to space heated are, in southern rooms, one square foot to 111 cubic feet; in the northern rooms, one square foot to 135 cubic feet; in the eastern rooms, one square foot to 123 cubic feet; in the great central hall, one square foot to 777 cubic feet.

The hall, containing four million cubic feet of space, is the regulating air-reservoir. The fresh air is introduced through the window-sills over steam-radiators placed in the window-breasts. The consumption of fuel has been about 700 tons per year.

While the external appearance of the building is not generally admired, and few architects would be willing to take it as a pattern, it seems well adapted to its purpose, being well lighted and ventilated, and conveniently arranged for the large force of clerks employed in it.

THE MYSTIC RIVER INVESTIGATION.

The Massachusetts State Board of Health has appointed Phineas Ball, C. E., of Worcester, H. A. Carson, C. E., of Boston, and Charles H. Swan, C. E., of Boston, a committee to investigate the sewage pollution of the Mystic River and means of prevention. The Engineer of the Board of Health is F. P. Stearns, C. E.

Gas and Electricity.

October 29.....	24.84	20.45	21.80	28.43	30.11	25.73	29.

E. G. LOVE, Ph.D., Gas Examiner.

The New York District Railway Company claims, in a circular letter, that the Court of Appeals has affirmed the constitutionality of the act under which it is organized. We note that a similar claim is made in the daily papers for the Arcade Railway. The money to carry out either of these schemes, however, is not forthcoming.

AN ACCIDENT AT THE NEW WATER-WORKS AT LITTLE ROCK.

PRESS dispatches state that the new water-works recently constructed by Colonel Zeb. Ward, at Little Rock, Ark., were to have been opened November 2, but, at 10 o'clock, the centre wall dividing the two new reservoirs, placed on a mountain 250 feet above the city, gave way, and allowed 10,000,000 gallons of water to run back down the mountain-side into the river. The lower reservoir was full, and the water from the upper rushed into it and caused it to overflow. The damage is \$10,000.

KIND WORDS FROM OUR CONTEMPORARIES.

WE are pleased to quote the friendly references of several of our esteemed contemporaries to our recent change of name:

[From the *Railroad Gazette*.]

"In noting this change of name we offer Mr. Meyer our congratulations on the success of his admirable journal, and assure him of our good wishes for its future. THE SANITARY ENGINEER has always been edited with a high ideal. No effort has been spared to make it the organ of the best opinion in the specialties it has treated, and it stands as a fine example of clean and able journalism."

[From the *Railroad and Engineering Journal*.]

"While a change in name of an established paper should always be avoided, if possible, there are in the present case some strong reasons for it. The new name expresses much better the real character and scope of the paper, while the old one was to some extent misleading, as indicating a more contracted field than that really occupied. THE ENGINEERING AND BUILDING RECORD is a paper whose excellence and independence merit continued prosperity, and should secure for it a wide circle of readers."

[From the *American Machinist*.]

"Our staunch and reliable contemporary, THE SANITARY ENGINEER, has changed its title, and will hereafter be known as THE ENGINEERING AND BUILDING RECORD, retaining the old name as a sub-title. We are more than persuaded that the character of our contemporary will undergo no change, so far as reliability and sterling integrity are concerned, and congratulate it upon having secured upon its editorial staff the services of Mr. H. W. Brinckerhoff, a member of the American Society of Civil Engineers, and a gentleman of well recognized talent, who will help to make the paper even more attractive than ever. We congratulate THE SANITARY ENGINEER upon the enviable position it has attained, and predict for THE ENGINEERING AND BUILDING RECORD still greater success."

PERSONAL.

MAJOR DALLAS BACHE, Surgeon U. S. A., has been transferred from Newport, R. I., to Fort Riley, Kansas.

LIEUTENANT OSCAR T. CROSBY, of New York City, resigned last week from the Engineer Corps of the Army.

HENRY B. HARRISON, architect, of Newark, N. J., died recently.

JOHN C. DAVIS, master builder for the Baltimore and Ohio Railroad, died November 1. He was born in Luzerne County, Pa., and was sixty-nine years old.

CAPTAIN F. A. HINMAN, Corps of Engineers, U. S. Army, for several years past in charge of the harbor improvements at Norfolk, Va., has been granted a leave of absence. He is the recipient of a letter enclosing a copy of very flattering resolutions, passed by the State Harbor Commissioners, showing their high appreciation of the services he has rendered the State in the work of harbor improvements carried on under his direction.

A REPORT is out to the effect that A. Gottlieb, of Chicago, of A. Gottlieb & Co., expects to buy an interest in the Mt. Vernon Bridge Company, Ohio, and locate there with them. The facts are that Mr. Gottlieb and his partner have become stockholders. He is the consulting engineer of the company, but remains in Chicago.

MR. E. F. FARRINGTON, of Brooklyn, Master Mechanic of the East River Bridge during the whole period of its construction, has accepted a similar position on the new dry-dock to be constructed at the Brooklyn Navy Yard by J. E. Simpson & Co., of this city.

MR. WILLIAM RUMBLE, of Bayonne, N. J., a member of the American Society of Civil Engineers, and for many years connected with the New York Steam Company as assistant engineer and superintendent, has opened an office at 22 Cortlandt Street, New York, as consulting civil and mechanical engineer.

E. TOWNSEND MIX, the well-known architect, of Milwaukee, is dangerously ill with an attack of congestion of the lungs. His work has given him a widespread reputation.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITIONS.

RAILWAY DEPOT AT HARTFORD.—The plans submitted by Shipley, Ruttan & Coolidge, successors to the late H. H. Richardson, of Boston, Mass., have been adopted by the committee for the New York, New Haven and Hartford Railway depot here, somewhat modified. The building material bids will be made on the basis of several kinds of stone, but some sort of granite in harmony with the surroundings will probably be chosen. The original plan presented a building to be built of red-veined granite, giving it a warm and stately appearance. It would have cost \$400,000 to have realized this plan, and so the change was made to fit \$150,000 or \$200,000.

SEE our "Proposal Columns" in regard to an advertisement calling upon architects to submit plans and specifications for the new New York City municipal building recently referred to in this column.

MADISON SQUARE GARDEN.—In the competition for plans for modifying this well-known resort of New York City, noticed recently by us, the prize plan has been ascertained to be that of Messrs. McKim, Mead & White, architects, of New York City. The estimated cost is \$1,500,000.

For works for which proposals are requested see also the "Proposal Column," pages 633-639-640-656.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE ENGINEERING & BUILDING RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

WATER. SEWERAGE, ETC.

HARRISVILLE, MICH.—Our correspondent writes: "There has not been anything done yet. Don't think there will be this fall."

WEST BRANCH, MICH.—Our correspondent writes: "There has been a little talk about water-works, but nothing done as yet."

MONTREAL, CAN.—Our correspondent writes: "On September 30, at a meeting of the Water Committee, the Superintendent reported in favor of laying larger water-mains in certain streets for improvement in the fire-service. The Committee resolved to ask Council for \$60,000 for the purpose, to be expended in accordance with Superintendent's recommendation, as follows: 1,200 tons of 12 and 10 inch pipe, \$43,200; 50 tons of specials, \$2,500; 4,000 pounds of brass tubing, \$1,200; 16,250 pounds of brass castings, \$4,062. Say, including contingencies, \$60,000. Council has not yet granted the appropriation asked."

NEW YORK CITY.—See our Proposals for reference to gate-houses on the New Croton Aqueduct.

ALBANY, GEO.—Water company here; capital stock of the Albany Water-Works Company will be from \$30,000 to \$50,000.

WEST DE PERE, WIS.—It has been decided to award the contract for boring an artesian well for water-works in West De Pere to Gray Bros., of Milwaukee. They offer to do the work for \$1.80 per foot, furnishing everything themselves, including the piping, etc.

GRAND RAPIDS, MICH.—We here give estimates of Consulting Engineer J. D. Cook's report to the City Council on better water-supply, which we have previously referred to:

Estimate 1—Briggs' farm reservoirs and pump-station, pumping-machinery, mains, settling reservoirs, etc., engineering and superintendence, \$328,500.

Estimate 2—Cost of low-service pumping-machinery at Briggs' farm, two 5,000,000-gallons low-service high-duty engines, with necessary appurtenances, including boilers, \$76,600.

Estimate 3—Cost of pumping-machinery for supplying the entire city from present sta-

tion, increasing capacity of present machinery to 10,000,000 per 24 hours, 5,000,000 high-duty pumping-engine, including boilers, etc., and superintendence, \$85,000.

Estimate No. 4—Stand-pipe construction, \$25,000.

Estimate No. 5—Revised distribution, including 275,480 feet of new pipe laid, special castings, Wyckoff log pipes, new hydrants, etc., \$330,000.

The summary of the plans in brief is as follows: No. 1, including the Briggs' farm pumping-station for supplying low-service district using present engine and plant for high service, including pipe distribution as per estimate No. 5, and stand-pipe as per estimate No. 4, total completed, \$775,100.

No. 2, Briggs' farm station as per estimate No. 1, pumping-machinery as per estimate No. 3, and pipe distribution as per estimates Nos. 4 and 5, total, \$768,500.

No. 3, Briggs' farm station, using present pumping-machinery for high and low service, 10,000,000 gallons capacity annex to boiler-room, pipe distribution and stand-pipe, total, \$703,500.

No. 4, Omitting Briggs' farm station and pumping from present station as per estimate No. 3, with capacity of 15,000,000 gallons, \$85,000; pipe distribution and stand-pipe, total, \$440,000. Omitting one engine, leaving pumping capacity 10,000,000 gallons, \$375,000.

City Council, October 27, voted to hold a city election to raise \$250,000.

SING SING, N. Y.—As to reports about water-works here, noticed by us some time since, our correspondent writes: "The Legislature of 1886-7 authorized the village of Sing Sing to raise, by bonding the village, the sum of \$150,000 for the purpose of constructing water-works. The act named five estimable gentlemen as commissioners to carry out the provisions of said act. From the apparent progress made thus far it would seem, that if it be true (as we were taught in childhood days), that this earth would eventually be destroyed by fire, that then, as now, there will go up from Sing Sing a long, lasting, but unavailing howl for water, water, water!"

ALBION, MICH.—Our correspondent writes in regard to the proposed water-works: "The matter is very new; only talked of. Have had plans, etc., made and committee appointed to ascertain cost of works."

JAMESTOWN, N. Y.—Charles B. Brush, C. E., of Hoboken, N. J., has examined the water-supply at Levant for the Jamestown Water Company and will report at once.

JAMESTOWN, N. Y.—Our correspondent writes: "The water company of this city have purchased about one hundred acres of land four miles from the city, and have put down four large wells which are flowing. The company proposes to supply the city from this source."

JERSEY CITY.—A 30-inch brick sewer will be built in Ogden Street, Kearney, November 28. Martin Fink is Clerk of Board of Public Works.

LEWISTOWN, ILL.—Incorporated is the Lewistown Water Company; capital stock, \$25,000. Incorporators, Lewis W. Ross, P. J. Stanard, and others.

LAKE, ILL.—The Board of Trustees held a special meeting, October 27, to take action on the water question. The board some time ago advertised for proposals for water-pipe, and it was for the purpose of awarding the contract that the meeting was held. The contract was awarded to J. B. Nichols, of the Shickle, Harris & Howard Iron Company, of St. Louis, at \$29.74 per ton of 2,000 pounds of 24-inch pipe. The amount of pipe required is about 27,000 feet and will cost about \$95,000.

WEST SUPERIOR, WIS.—We have made several references to the proposed water-works here. The contract has gone to the Superior Water-Works Company.

STRATFORD, CONN.—Our correspondent writes: "We have no water-works and none in contemplation."

PONTIAC, MICH.—Bids for constructing water-works here will be opened December 21. The works are designed by J. D. Cook, C. E., of Toledo, O.

SAN DIEGO, CAL.—The Coronado Beach Company has entered into a contract with S. W. Howland to sink a well on the North Island. He is, according to the terms of the contract, to secure a supply of water equivalent to 2,000,000 gallons in every twenty-four hours.

The Beach Company is also closing a contract with D. Schuyler, by the terms of which the company agrees to pay him \$30,000 if, after sinking a shaft 3,000 feet, he shall strike water, gas, or oil.

LANCASTER, PA.—At the meeting of the Special Committee on Water-Works Improvements, November 1, bids were opened for laying the new water-main from the pumping-station to the reservoir, as follows: B. Malone, 75c. per lineal foot; Kitch & Smith, \$8.24 per joint of 12 feet; C. Schwebel, \$1 per lineal foot; F. Hinden, \$7.20 per joint. The contract was awarded to F. Hinden at \$7.20 per joint, to be laid under the supervision of the Superintendent of the Water-Works.

PHILADELPHIA, PA.—Councils, Sub-Committee on Water on the question of granting authority to the Holmesburg, Pa., Water Company and the Diston Water Company to erect works and lay mains in the upper portion of the Twenty-third Ward, met November 1. One ordinance under consideration authorizes the Holmesburg Water Company to build works and lay pipes to furnish water for district known as Oxford and Lower Dublin townships, and the other authorizes the Diston Company to extend its mains in the section bounded by Leverick Street, Pognessing Creek, and the Delaware River.

SYRACUSE, N. Y.—The new bids for the building of a 60-inch brick sewer were opened by Council October 31, and the contract given to Martin Sprague & Co., at \$28,070. Mr. Dillon bid \$29,948, and Patrick Ready, \$30,768.

NEWARK, N. J.—Bids for constructing new basins on the Bloomfield Avenue sewer were recently rejected, and are readvertised for by the Sewer Committee of Council. Contract for sewer, except basins, has been awarded to James Coneroy.

MALDEN, MASS.—The ordinance to raise \$15,000 for a pumping-station at Spot Pond has been vetoed by the Mayor and killed.

EAU CLAIRE, WIS.—The village of Hayward, Sawyer County, is about to build water-works to cost \$15,000 or \$20,000.

ROCHESTER, N. Y.—First ordinances have just passed city council appropriating \$4,000 to the construction of the Genesee Valley outlet sewer, and some smaller sewers.

HAYWARDS, CAL.—William Hayward and Mr. Knox are sinking wells for water-supply for the town. Machinery is wanted, and a reservoir will be built. Immediate attention is necessary.

ELYRIA, O.—Our correspondent writes: "The Elyria Gas and Water Company are building a stone dam across Black River about one-half mile above their present dam, which will make a reservoir over two miles in length and contain about 100,000,000 gallons of water. Their present capacity is about 50,000,000 gallons. With the addition of the reservoir now building it would hardly carry us through the drouth we now have."

WATER-WORKS are proposed in the following towns: Barre, Ont., Can.; Cedar Falls, Mich., plans preparing; Hendersonville, N. C., cost \$12,000; Georgetown, Ky., franchise wanted; Bristol and Goodson, Va., surveys by Howard Murphy, C. E. of Philadelphia; Fort Valley, Kan.; S. B. Burr; Green Cove Springs, Fla.; J. S. Wright; Clarksburg, W. Va.; T. M. Jackson, Consulting Engineer; Georgetown, Ky.; Trenton, Ill.; Carlyle, Ill.; Missouri Valley, Iowa, \$25,000; Norfolk, Neb., A. C. Clark, et al.; York, Neb., A. C. Clark, et al.; Clinton, Ill.

SAINT SAUVEUR, QUEBEC, CAN., wants plans for water-works submitted to the Municipal Council by December 1.

GAS AND ELECTRIC-LIGHTING.

LYONS, KAN.—An electric-light plant is to be placed in Lyons for street-lighting.

MT. VERNON, N. Y.—At a meeting October 26 of the trustees of Mt. Vernon, it was proposed to make a contract with the American Electric Manufacturing Company for a plant of fifty arc-lights to be put up within a short time for lighting the principal streets and avenues. It was also suggested that proposals be invited from different gas companies for lighting the streets with gas.

HOLMES COUNTY, O. Gas and Oil Company has just been incorporated.

ERIE, PA.—The Columbia Gas-Light and Fuel Company (natural gas), with C. N. Payne as President, and James Miller as Secretary. A new pipe-line will be laid, and the main offices will be moved to Corry, Pa.

SAN JOSE, CAL.—The contract was let October 24 by the Trustees of the Hospital for the Chronic Insane at Agnews to A. F. Nye & Co., of San Francisco, to furnish a 500-light gas-machine for \$3,000.

SAN FRANCISCO, CAL.—Address the San Francisco Gas-Light Company about new works to be built for the Lowe process.

FORT WAYNE, IND.—Ordinance to grant franchise has passed City Council for the Standard Gas, Fuel and Steam Company, to establish works in the city and to lay mains through the streets, providing they furnish gas to consumers at not more than 75 cents per 1,000 feet.

ERIE, PA., Gas Company will enlarge its plant. Work on the receiver has been begun. When complete it will have a capacity of 210,000 cubic feet, and, with the smaller one adjoining, will hold 310,000 cubic feet. Superintendent Fish, representing Deily & Fowler, who have the contract for the iron-work, says the new receiver will be completed within two months.

SOVERVILLE, TENN., wants better street-lighting.

CHICAGO.—City Electrician Barrett is ordered by the Common Council to prepare estimates for a plant for lighting by electricity a square mile on the West Side of Chicago.

LAREDO, TEX.—A company (Ex-Gov. A. C. Hunt, of Colorado) has obtained a franchise to put in electric-lights.

MACON, MO.—The Standard Gas and Electric-Light Company, of Independence, Iowa, has put in gas-works here.

AMSTERDAM, N. Y., has contracted with the Thomson-Houston Electric Company, of Boston, for 100 street-lamps.

LOCKHAVEN, PA.—Chartered is the Lockhaven Electric-Light and Power Company; capital, \$20,000.

COLLINSVILLE, ILL.—County Treasurer Joseph H. Wickliffe has made the city a proposition to put up an electric-light plant. He asks a twenty-year franchise, the city to use his lights or not as they see fit, the prices charged for lights after the plant is in working order to be regulated by the average price paid for like lights in St. Louis, Kansas City, St. Joseph, Sedalia, and Jefferson City, Mo. The matter has been laid over for one month.

JEFFERSON, IOWA.—Private enterprise is developing gas wells and plant here.

GAS AND ELECTRIC-LIGHT COMPANIES, ILLINOIS.—Incorporated is the Eureka Gas and Oil Company, at East St. Louis; capital stock, \$3,000,000; incorporators, H. T. Mudd, W. H. Swan, and W. C. Bragg. The Edwardsville Light and Power Company, of Edwardsville, Ill.; capital stock, \$10,000; incorporators, C. L. Cook, W. P. Bradshaw, E. J. Jeffres. The Consumers' Electric-Light Company, of Chicago; capital stock, \$15,000; incorporators, J. C. Schumacher, M. Wilmersdorf, A. Melges.

LISBON, N. H.—Address the Town Clerk about a proposed electric-light plant here.

PORTLAND, ME., has contracted with the Consolidated Electric-Light Company for 168 arc lights and 250 incandescent lights, at \$25,000 per annum; \$1.40 per annum for each additional arc light, and \$18 per annum for each additional incandescent light.

BATTLE CREEK, MICH.—The Battle Creek Electric-Light and Power Company have been incorporated. W. A. Foot and others.

STEAM-HEATING, BUILDINGS, ETC.

WINFIELD, KAN.—The Missouri Pacific Railway Company has purchased land adjoining this city and completed arrangements with the Board of Trade for the location of machine and repair shops for the entire system of the Denver, Memphis and Atlantic Division in Kansas, embracing about 500 miles of road. The contracts entered into call for the expenditure of \$50,000 in buildings, exclusive of machinery.

THE ENGINEERING & BUILDING RECORD

AND THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1887, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 16. }
NUMBER 24. } PUBLISHED EVERY SATURDAY.

NEW YORK, NOVEMBER 12, 1887.

LONDON, NOVEMBER 26, 1887.

SINGLE COPIES, TEN CENTS.
Subscription, \$4.00 per year in advance, post paid. } IN AMERICA
SINGLE COPIES, SIXPENCE.
Subscription, 20s. per annum in advance, post paid. } IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD,
conducted by HENRY C. MEYER, is published every Saturday at 82 & 84 Fulton Street, New York. Its opinions upon all technical subjects are either prepared or revised by specialists.

TERMS, \$4 PER YEAR, IN ADVANCE.

Postage Paid.

OFFICE IN GREAT BRITAIN,
98 & 92 FLEET ST., LONDON.

TERMS, 20s. PER YEAR, IN ADVANCE. Postage Paid.
SINGLE COPIES, SIXPENCE.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York), and crossed — & Co.

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 20, Leipzig, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, \$5; China, Japan, Sandwich Islands, Mexico and Cuba, \$5; South America, \$4.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us promptly of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired both the old and new addresses should be given.

THE BURSTING OF THE LITTLE ROCK RESERVOIR.

THIS occurrence, which was briefly noticed in our last issue, and of which a more detailed account may be found on another page, almost excites a smile. Just two hours before the time fixed for the formal opening of the new water-works, the water-works spontaneously opened themselves on a much more extensive scale than was contemplated, and more than 10,000,000 gallons of water rushed roaring down the mountain side, leaving nearly \$10,000 worth of ruin behind them.

The contractor and owner whose work was thus suddenly swept away is reported to have said: "It was rather expensive entertainment, but it was undoubtedly the grandest sight I ever witnessed." It is to be hoped that it has ere this occurred to him that a few hundred dollars spent for the advice of a competent engineer would have made him a much richer man to-day both in pocket and prestige, to say nothing of the many lives that might have been sacrificed by his blundering had the accident occurred two hours later. Whether, however, the contractor takes this view of it or not, the citizens of Little Rock, if they wish to have a reliable water-supply and to protect their own lives and property, cannot do less than insist that the work shall not be rebuilt except upon plans that have been approved by some well-qualified engineer.

There is no evidence that the contractor intentionally slighted the work in the reservoir walls; on the contrary, their overthrow *en masse* would indicate that the masonry was good, but that either the design was faulty or the foundation defective, and it is precisely on these points that the "practical man" would be most likely to fail and that the engineer would be of most service. As to the design, it may be said that Trautwine's rules would require a breadth of base about 50 per cent. greater, and the leakage suggests defective foundation.

This accident and the fall of the water-towers at Franklin and Seneca Falls, the former of which we illustrated last week and the latter described in this issue, should serve to remind those who have to do with elevated reservoirs of any kind that if badly designed, built, or managed they are about as dangerous as dynamite and rather more certain, in the long run, to cause disaster.

We do not wish to say a word to hinder in any way the building of water-works. They are an inestimable blessing in many ways to every community fortunate enough to possess them, and it cannot be supposed that small towns can afford to build them in the style or solidity that should characterize those of larger cities, but they should at least be safe, and if contractors of the energy and enterprise displayed at Little Rock will remember the advice of Davy Crockett, and with the help of some good engineer make "sure they are right before they go ahead," this most desirable result will be accomplished.

THE NEW YORK QUARANTINE AND CHOLERA.

THE statement of Mayor Hewitt in his letter to President Cleveland, that "there is a feeling in the community that greater care and efficiency are necessary in order to protect this city and the country at large from the consequences of the landing of passengers who may have the

germs of disease which may be developed at a later date," is undoubtedly correct, and this feeling exists in all parts of the country. The report of the Committee of the College of Physicians of Philadelphia on the efficiency of our quarantine arrangements is a fair and candid document. It clearly recognizes that the quarantine establishments of Philadelphia and Baltimore are much less fitted to deal with imported disease than is that of New York, and it makes it very clear that the management of the New York Quarantine as regards the passengers of the cholera ship "Alesia" has been very unsatisfactory.

The practical question is, What is to be done about it? The Philadelphia committee recommends that all our maritime quarantines be put into the hands of the National Government. This is the course which this journal has always recommended, because we are satisfied that it is the only way by which both the business interests of the community can be protected and freedom from importation of small-pox, cholera, and yellow fever be secured.

Hitherto, however, the personal interests of about a dozen health officials and the opposition of the Treasury Department at Washington to the late National Board of Health have been sufficiently powerful to prevent Federal legislation on the subject, and it is probable that they will continue to be powerful until some widespread epidemic occurs. The action of Congress on this subject depends on the representatives from the interior and Western States, and, to a considerable extent, on the action taken by the health authorities of these States. Probably this matter will be discussed at the meeting of the American Public Health Association in Memphis this week. Meantime is there anything which can be done immediately to lessen the danger? Our suggestion is that passenger steamers from ports infected with cholera be not allowed to land passengers or freight on our shores. It is very possible that the Secretary of the Treasury has power to enforce such a regulation as this through the Custom-House authorities. Mayor Hewitt suggests to the President that a friendly representation made to the Italian Government might secure greater precautions in the clearance of vessels from the cholera regions. So far as the port of New York is concerned it would seem that the Governor of the State might well take some action in view of the facts brought out in the report of the Philadelphia committee. And, as has been hinted above, the health authorities of the interior States have a good deal of power to induce quarantine officials to do their duty. We hope that all these influences will be brought to bear in such a way as not only to avert the immediate and pressing danger, but to put the whole maritime quarantine of the country on a proper basis.

DESTRUCTION OF THE NEW YORK CITY HALL AND PARK.

WE have spoken with approval and admiration of the efforts of Mayor Hewitt to increase the number of parks in this city, particularly in the lower part of the city, which was laid out before the sanitary and moral necessity for breathing places in a large city was understood. We now again protest against the proposed appropriation by Mayor Hewitt and his colleagues of a large part of the City Hall Park to build-

A. PAGE BROWN, ARCHITECT.

ing purposes, as shown in the accompanying cut. This involves not only the loss of green-sward and trees in the only park, except the Battery, below Third Street, but also the dwarfing and, architecturally speaking, killing of one of the finest specimens of classic architecture to be found anywhere, by the erection of two large "wings" to the present City Hall building.

The criminal courts should, undoubtedly, as recommended in Alderman Conkling's resolution offered on November 1, be removed to the block now occupied by the old New York and New Haven freight depot, which is owned by the city, and the demoralizing spectacle, shown daily, by the transportation of criminals through our streets, be thus abolished. The city offices which require proximity to the City Hall could be transferred to the north side of Chambers Street upon the new block formed by opening Elm Street to Chambers, and the buildings other than the City Hall and the Court House should ultimately be removed from the park.

Now, however, that plans have been asked for and some fifteen thousand dollars are to be expended for them, we trust that this scheme will progress no further than the securing of them. This expenditure and the result of the competition in securing designs, will, we hope, demonstrate to those hitherto incapable of appreciating the fact that the present architectural beauties of the City Hall will be destroyed, together with the little breathing space yet left in the park.

SUBURBAN RAPID TRANSIT RAILROAD.

THE *Yonkers Statesman* says that "great indignation exists among the people of the Twenty-third and Twenty-fourth wards at the attempt of a few owners of property on One Hundred and Twenty-ninth Street to defeat the proposed improvements" of the Suburban Rapid Transit Railroad of this city. This corporation has set a good example in honestly building a road on property that it has paid for. It therefore deserves consideration and encouragement.

Factionous and unreasonable opposition on the part of a few property-owners in dealing with a corporation disposed to act fairly is not to be commended.

The Suburban Company needs extra land for the proper conduct of its growing business, and it is willing to pay a fair price for it. It is to be hoped, therefore, that needless obstacles to its acquiring it will soon be removed.

We desire to state, for the information of our esteemed English contemporary, *Iron*, that the Japanese have not stolen a march on Western civilization by the establishment, in the Imperial University of Japan, of a chair of sanitary engineering, as such a chair was established at Columbia College, New York, in 1885.

PROPOSED NATIONAL LEGISLATION ON FOOD ADULTERATION.

THE *American Grocer* announces that a convention is to assemble in Washington on January 19 next, in which representatives from the mercantile interests are expected to co-operate with representatives from the various sanitary associations of the country to secure concerted effort to induce the next Congress to enact a law against food and drug adulteration.

Our contemporary prints a draft of the bill prepared by the committee of experts appointed by the National Board of Trade some years since, which, it will be remembered, consisted of Dr. J. S. Billings, U. S. A., Professor Charles F. Chandler, of New York, ex-Chancellor Williamson, of New Jersey, and Mr. A. H. Hardy, of Boston. The draft of the bill submitted by these gentlemen and afterwards endorsed by the National Board of Trade is the basis of the food adulteration legislation of the States of New York, New Jersey, and Massachusetts. Massachusetts and New Jersey have done some good work under it, and at the last meeting of the New Jersey State Sanitary Association resolutions were adopted endorsing the proposed convention to be held in Washington. Several attempts were made a few years since to secure national legislation on this subject, but interstate commerce questions, upon which Congress was at the time divided, prevented the passage of anything like an effective measure. It is encouraging to see the commercial interests of the country moving in this direction, and if it is proposed to enact anything like such a law as that of which the National Board of Trade secured a draft from the gentlemen we have named, they deserve the co-operation and support of our sanitary authorities. While recent investigations

have shown that there is comparatively little food adulteration in this State dangerous to health, we don't believe as much can be said for the condition of the drug market, nor that so satisfactory a state of things exists in other States where there are no checks on dishonest manufacture. Congress should certainly take measures to protect the honest merchants in one portion of the country from the unfair competition of unrestrained trickery in another.

THE ARCHÆOLOGICAL INSTITUTE OF AMERICA.

FROM the eighth annual report of the Archæological Institute of America we learn that the institute has undertaken directly the prosecution of no great work during the past year. The American School of Classical Studies at Athens being founded by the institute, the

credit of work done by members of the school may be fairly in part given to the institute.

Members of the school, aided by funds presented by the institute, have investigated the remains of the theatre at Thorikos. They have also started the exploration of the more important theatre at Sikyon, which promises rich discoveries. The foundation-walls for the school building have been completed. Under the auspices of the New York society there have been given during the past year in aid of the endowment fund of the school, a representation by students of the University of Pennsylvania of Aristophanes' "Acharnians," four lectures, by Dr. Waldstein, Professor Gildersleeve, Professor Merriam, and Professor Goodwin; and two courses of lectures by Professor Lanciani, Director of Excavations for the City and Province of Rome, all of which have been financially successful. A very successful public dinner was given at which Mr. George William Curtis presided; the principal speeches were made by Mr. James Russell Lowell and Dr. Waldstein, the newly appointed Director of the School.

THE Milwaukee Common Council have passed a bill making it compulsory for owners of theatres to put in 3-inch iron pipes connected with the city water-mains and reaching to the stage, such pipe to have a valve conveniently located and sufficient size to supply a 2½-inch hose.

ARRANGEMENT AND CONSTRUCTION OF SMALL HOSPITALS.

THE Medical Officers of Schools Association has printed a paper by Dr. Charles E. Paget on the "Arrangement and Construction of School Sanatoria," in which are given some very good plans for small hospitals of from six to thirty beds. These are intended especially for boarding schools having fifty or more pupils, and one great object kept in view is to limit the spread of such diseases as measles, scarlet fever, etc., by providing means for the prompt isolation of the first cases. Dr. Paget is the Medical Officer of Health of Westmoreland, and his remarks on the site, construction, and sanitary arrangements for such small hospitals are concise and judicious. Those who are interested in the construction of institutions of this kind will find that a shilling is well invested in the purchase of this pamphlet, which is published by J. and A. Churchill of London.

CITIZENS of Charleston and other earthquake points will be glad to learn that earthquakes may be foretold, or, at least, so Professor Milne asserted before the Japan Seismological Society, according to *Iron* of September 30. Before a shock, which was felt in Japan last January, horses pranced in their stalls half a minute before it occurred. It has also been found that pheasants scream and frogs suddenly cease croaking, while geese, pigs, and dogs give the clearest indications of an approaching quake, though the Professor omits to mention how they do it.

A DEFICIENCY OF NATURAL GAS.

THE supply of natural gas at Wheeling, W. Va., is proving unequal to the demand, and the gas-works are in consequence being bored deeper, which it is believed will result in an increased flow.

THE State Board of Health of Ohio have published a manual for the use of boards of health, containing the State statutes relating to the public health and the decisions of the Supreme Court of the State on certain points connected with this subject. Many of the statutes were enacted years ago, but the board mildly states the case by saying that "it is not exceeding the bounds of truth to say that not sufficient attention has been given to their due enforcement."

OUR ARCHITECTURAL ILLUSTRATIONS.

THORNWALL ORPHANAGE, CLINTON, S. C.—A. PAGE BROWN, ARCHITECT.

THE subject of our vignette illustration is the Thornwall Orphanage at Clinton, S. C. It is built of local stone and brick. The second story of unstained cypress shingles; interior of oak and yellow pine; hardwood ceiling on

first floor. It is one of a group called the Thornwall Orphanage, and is in charge of Professor William P. Jacobs, D. D. It was the gift of Mrs. Cyrus H. McCormick, of Chicago.

OLD COLONIAL SKETCHES, FREDERICKSBURG AND ANNAPOLIS, MD.

(Continued from page 647.)

There are three boilers, shown at *b b b*, placed parallel in position and inclosed in a separate room, with ample space for storing all coal needed, as this shaft is convenient to transportation, being located only a short distance from railroad and Harlem River. The total capacity of these boilers is 210 horse-power. An Otis hoist is located

FIG. 90.

A partition extends from brick masonry inclosing the boilers to a point near door at 1, separating the engine-room from boiler-room.

The dynamo is favorably located at end of engine-room at *e*, and the air-receiving chamber of the duplex Rand compressor is better located for receiving pure air than at Shaft 22, as it is more than twenty feet from entrance *o*

The feed-pump *A* is also favorably located for safety near the boilers, and a similar location can be found in the feed-pumps at Shafts 12 to 20, except 19. The plant in Shaft 21 is not as compactly located as shown at Shaft 22, as the engineer can see only a portion of the machinery without climbing a flight of steps at *m*, which, in case of an accident to hoist or blower engine, would cause serious delay before he could give it attention, and a lazy man would neglect them. Had this plant been located ten feet further from the shaft, all the parts could have been set on the

FIG. 91.

At Shaft 13 the hoist is in one building and the boiler and engines in another. The engine and dynamos here are placed in a diagonal position from the compressor, but would have been more favorably located at the side. The Lidgerwood joist is 18 feet from head-house, and hoist 23 feet from the compressors, with about 20 feet space between the two buildings. The plant at Shaft 19 is spread out over a large area; the principal members composing this plant appear to have been arranged in the form of a parallelogram, the boilers at one end and a Dickson hoist about 38 feet from them at the other end, with only an engine on one side between them. A Rand compressor is placed on the side of this parallelogram opposite the engine and 26 feet from it and 22 feet from the boiler, which leaves a clear unoccupied space between them with an area of about 200 square feet. This useless space increases the area to be inclosed. At Shafts 16, 17, and 20 the dynamos are placed either over or under the

blowers. From South Yonkers to Harlem River the water-supply for the boilers is obtained from the Old Croton Aqueduct, but northerly from South Yonkers to a point where the New Aqueduct crosses the Saw Mill River near Shaft 12 the supply is obtained from Saw Mill River. The line of the Old Aqueduct is inclined westerly at South Yonkers to the heights bordering the Hudson River, which it continues to follow to the Croton Dam; his water-supply, therefore, is not available above the former place.

Water-tanks are stationed at Shafts 16 and 17 for the purpose of storing water, and feed-water heaters are used at Shafts 13, 17, and 19 to economize fuel by heating the water before entering boilers, which is principally accomplished by utilizing the exhaust steam.

(TO BE CONTINUED.)

BUILDING CONSTRUCTION DETAILS.

No. VIII.

(Continued from page 432.)

GRAIN-ELEVATORS.

THE huge, ungainly structures erected for the purpose of handling, storing, and distributing grain are almost unique to this country, being practically unknown in Europe, and their construction and internal dispositions are so essentially products of native genius that, as far as pure construction is concerned, hardly anything could be found which would be more typically American. In fact, such construction would be impracticable anywhere except in a country where lumber was cheap and available land very expensive, conditions which have been realized to a marked extent in the large cities of the upper Mississippi valley, the greatest wheat and corn growing country in the world. A grain-elevator is required to have a capacity for millions of bushels of grain, and yet to cover as little surface as possible; to be entirely open underneath, so as to permit of trains of cars being loaded and unloaded within the building; to be light of construction, capable of being easily, quickly, and cheaply erected, and yet of strength sufficient to stand all jars and disturbances from adjacent railroad traffic. That all these conditions have been fulfilled is due to the energy, pluck, and adaptability to circumstances which mark so many of our Western con-

Fig. 1.
Plan of Piling.

structions. The original of the present mammoth grain-elevator, with all its complication of bins, shoots, and lifts, was doubtless the split-rail corn-crib, so familiar an object throughout the West, built with long rails or logs lapped over each other at the angles and set two or three feet above the ground. The difference between that and the elevator, with its walls of lapped plank laid flatwise and nailed together, and raised on a trestle-work of heavy timbers, is a difference of extent more than of kind.

The various large elevators throughout the country are so nearly identical in construction, that for present purposes of illustration it will suffice to consider the methods in use in Chicago, where this kind of building has attained its highest development. From necessity, most of the elevators in this city have been built on the banks of the river, where no natural foundation can be found anywhere near the surface of the ground. Piling has consequently to be employed. Fig. 1 shows the arrangement of piles under the foundations of the new Rock Island Elevator, and Fig. 2 illustrates the construction up to the ground-level. The piles are from twenty to forty feet

long, being driven down to hard pan. The butts are twelve to fourteen inches across. From observations made at the time the piles were driven, it is safely assumed that each pile will sustain a load of twenty-five tons. The maximum load on the foundations, shown by Figs. 1 and 2, is seven and three-quarters tons per square foot or about 22.15 tons to each pile. Over the piles are laid continuous rows of 4x14 sleepers extended across the entire building and above these are similar rows of 4x12 timbers. The masonry pier foundations are started upon this double-timbered

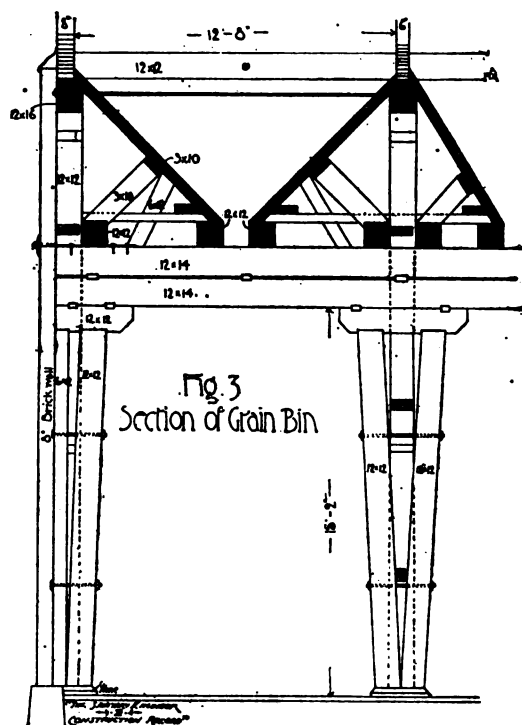

Fig. 2
Section of Foundations.

deck and the entire timber-work is covered with a closely laid floor of 3x12 plank. The masonry piers are carried up to a few inches above the street grade, where a second floor is laid over the whole area, sleepers for the railroad tracks being laid across between the piers.

Figures 3 and 4 illustrate the superstructure of one of the L. C. Huck Brewing Company's elevators, which is practically the same as the Rock Island elevator. The

interior of the elevator on the ground-level is entirely open except for the grouped posts for the support of the bins above. The trains of loaded cars are run in on tracks between the posts and the grain shot down into the space under the floor, from where it is raised by scoops, chains, screws, or some such contrivance, to the very top of the building. Thence it is distributed into the various bins,

and finally drawn off from the bottom into other cars for reshipment.

The bins are supported on double sets of 12x12 posts, as shown by Fig. 3 and Fig. 4, two of the posts carrying the double 12x14 timbers which are extended across the building to sustain the 12x12 cross-beams directly under the bins, while the other two posts run up by the flared bin bottoms and carry the partitions. The whole upper portion of the building is divided into separate bins corresponding to the spaces between the posts below. The partitions and walls are made of two-inch planks, four to ten inches wide, laid solid one over the other, and spiked

together. As the joints of the timbers are carefully broken the whole of the bins are tied together in the firmest possible manner, additional stiffness being secured by cross and diagonal rods through the bins at different heights.

As the grain is frequently piled as high as eighty feet in the bins, it will be readily understood what a tremendous load is brought upon the posts. In the larger elevators the posts are of necessity of oak, sometimes as heavy as 16x16, and to ensure an even bearing the stone cap on which they rest is covered with a sheet of lead. The necks of the bins are closed by iron valves.

Most of the elevators in Chicago are cased in brick through the first story, and occasionally the brick-work is

Fig. 5 Plan of a portion of Store House.

carried to the roof; but the masonry is a mere screen against fire or the weather, and the real supporting construction is in the posts. The brick walls never support anything but their own weight. Where the wooden walls are exposed it is customary to cover them with tin or gal-

vanized iron. The roofs are invariably of slate. The outward appearance of a grain-elevator is familiar to every one. The grain-bins extend as high as the first or lower roof. The central portion, rising like the clearstory story of a Latin church, is occupied entirely by the ducts, shoots, gearings, etc., used for distributing the grain to the various bins.

It is sometimes found desirable to store the grain by itself and keep the elevator-bins for transient traffic. In such a case a storehouse is built adjoining the elevator. Figure 5 shows the plan of the storehouse of the Charles Dole & Co.'s Annex D Elevator. The entire store comprises a rectangle of four times the area shown by this plan, being about 100x120, the whole divided into only three

Fig. 6 Part Section of Store House

huge bins, each of which is constantly filled with grain to a depth of nearly sixty feet. Figure 7 shows a section of an exterior buttress and elevations of a line of interior posts and of the braced partition separating the bins. The storehouse was built without any foundation whatever, and the floor is hardly more than a foot above the water in the

Fig. 7: Foot of an exterior Buttress

river. The ground was leveled as low as possible without striking water, all pockets and loose places in the soil carefully filled and the area covered with a thick layer of sand. On this railroad-ties were bedded, side by side, over the site to be covered by the building, and above these were laid 10x10 sleepers, about thirty inches on centres. A heavy plank floor and a matched upper flooring completed the foundation-work. The outer wall was started with 2x8

planks laid flat and nailed together. At a height of 22 feet 6 inches these were reduced to 2x6 and the upper twenty feet of wall were laid with 2x4 timbers. The interior posts ran from 12x12 oak at the bottom to 6x6 pine at the top, and besides being connected by four tiers of 10-inch cross-timbers, were tied together and to the walls by cross and diagonal iron rods varying from one inch to inch and seven-eighths diameter, arranged as shown by Fig. 5 and Fig. 6. The bin partitions were made with 2x6 and 2x4-inch timbers braced on either side with 10x10 and 8x8 struts, so that there would be no weakness in case one bin were emptied while the other remained full. And finally a gallery was carried around the storehouse inside, near the top, not shown on the drawings, and the walls and roof were covered with tin. The building has settled considerably in the centre, apparently as much as sixteen inches, but it is so firmly tied together in all its parts that the settlement has not affected it in the least for storage purposes.

All of the buildings above referred to were erected from the plans of Messrs. Baumann & Lotz, architects, of Chicago, to whom the writer is indebted for the drawings as well as for professional courtesies during personal investigations.

ON THE MANUFACTURE OF HYDRAULIC CEMENT FROM BLAST-FURNACE SLAG.*

In a paper entitled, "Hydraulic Cement from Cleveland Slag," published in the "Proceedings of the Cleveland Institution of Civil Engineers," No. 4, Session 1886-87, page 93 *et seq.*, Mr. J. E. Stead calls attention to two methods which have been applied to attain this object. One of these consists in taking 70 per cent. of slag sand, produced by Wood's process, and grinding it with 15 per cent. lime and 15 per cent. oxide of iron. The grinding is generally done wet, and the product requires to be used within a few hours of being made. Mr. Stead publishes an analysis of such a "cement," which shows: Lime, 22.90; silica, 21.61; alumina, 19.85; ferric oxide, 8.80; ferrous oxide, 4.00; magnesia, 4.36; water, 12.00. The rest of the analysis, which it is not necessary to quote in full, gives the usual non-essential ingredients. Of this so-called cement it may be remarked that it is, in point of fact, both by analysis and mode of manufacture, a mortar; and a very similar body might be produced by grinding burnt ballast, lime, and oxide of iron together. Nearly the whole of the lime present is there as free lime, and in no sort of really intimate combination with the silica and alumina. It is hardly necessary to say that such a manufacture would only interest ironmasters to the extent that they could use the product in repairs and building operations on their own premises.

The second process described is of greater interest, for it at least gives a product capable of being packed and sent into the market for sale. Briefly, it consists in grinding 75 per cent. of dry slag sand with 25 per cent. of dry-slacked lime, according to Mr. Larsen's patent. Great stress is laid upon the necessity of the most intimate mixture and minute pulverization of the ingredients, and a special machine, called by the patentee a "homogenizer," is used for the purpose. An analysis given on page 129 shows: Lime, 39.68; carbonate of lime, 4.07 = 41.96 total lime; silica, 24.34; alumina, 18.74; ferric oxide, 0.14; ferrous oxide, 0.27; magnesia, 6.59; water, 4.70. The rest of the analysis shows the usual non-essential ingredients and the two oxides of iron here mentioned may be classed in the same category. They are here merely quoted in order to make this analysis comparable with that given of the mortar made by the wet process.

The substance thus produced is shown by Mr. Stead to possess many very valuable properties, and he gives very full details of the various tests to which it has been submitted, and which it appears to have borne in a very satisfactory manner. In the discussion which followed the paper, the slag cement had, as might be expected, to bear comparison with the celebrated "Portland," a cement manufactured on a most gigantic scale from chalk and clay ground together wet, dried and burnt to incipient fusion, and finally ground for use. The general feeling of the meeting was that the test of time was the one thing requisite, and while Mr. Casebourne stated that he found that slag cement could, after three months' exposure, be scraped off with a knife, another gentleman considered that about ten years were necessary before a true judgment could be arrived at.

I am not concerned in this paper to dispute the necessity for a very long period for a fair judgment to be arrived at

* By R. J. Friswell, F. C. S., F. I. C., etc., in the *Engineer*.

in such a matter; for I consider that there are *prima facie* grounds for deferring a decision, and these are the very different chemical composition, as shown by analysis; and constitution, as shown by mode of production, of the two articles. Portland cement should consist of: Lime, 60; silica, 23; alumina, 8; the remaining 9 per cent. consisting of various non-essential ingredients. As a matter of fact, the above proportions are very closely adhered to by manufacturers, as shown by the analysis of the finished product. The substances above should be heated together in intimate mixture to a temperature approaching the melting point of cast iron. After this process scarcely any lime should exist as free lime.

Now, it is only necessary to tabulate the lime, alumina, and silica in either the dry or wet process cements described by Mr. Stead, together with "Portland," in order to show that there is a great difference in composition. For this purpose I have selected two Portlands varying very considerably:

	Portland 1.	Portland 2.	Wet Slag.	Larsen's Dry Slag.
Lime.....	59.90	55.57	22.90	41.96
Silica.....	24.07	22.92	21.61	24.34
Alumina ..	6.92	8.00	19.85	18.74

It will be seen that in the wet slag cement the lime is only about half that in the Portland poorest in lime, and even in Larsen's it is only four-fifths; the silica is about the same in all, while the alumina is nearly three times as much in the two slag compounds as in the true Portland. These differences are sufficiently large to attract attention, and though no one will pretend to say that a hydraulic cement cannot be made with such low proportions of lime, yet it must be admitted that the valuable properties which have made "Portland" a household word in every country under the sun are only exhibited by cements showing over 50 parts of lime to about 30 parts of silica and alumina. When we come to the constitution of the cement differences quite as important present themselves. In both the wet slag and dry slag processes only a portion of the lime, and that much the smaller, is in actual combination with the silica and alumina, by far the greater part—about three-fourths—is there as free lime. In Portland there should be little or no free lime, and, as a matter of fact, the semi-fusion of the mass insures this.

While Mr. Stead has thus dealt with two processes, both of them capable of yielding valuable products, there is yet a third which he has not noticed, capable of giving a more valuable cement than either. This is Ransome's process, which consists in an exact following of the Portland methods, save that slag is used instead of clay. Slag, sand, and chalk are ground together wet, and subsequently burnt to a true "clinker." The proportion of chalk used is in weight approximately equal to that of the slag, and this ensures a mixture such that, when burnt, it will closely approach in analysis the ratios of lime to silica and alumina shown by the Portland. Moreover, the burning causes that incipient fusion so requisite to secure a sound cement. On this, and kindred points, I may here quote a recent article by myself which appeared in the *Engineer* of March 4, 1887:

	Middlebrough slag.			Portland cements.	
	1	2	3	1	2
Alumina and silica.....	52.34	51.22	50.08	30.99	30.92
Lime.....	40.00	26.88	40.45	59.00	55.57

"From this it will be seen that in the slag the ratio of lime to the two other bodies is about 39.51, while in the cement it is 58.31. A simple calculation will show that on this basis the 39 + 51 = 90, or including the other bodies, 100 parts of slag requires the addition of 56 parts of lime = 100 parts of calcium carbonate—i. e., dry chalk or limestone—to give a substance yielding a good cement. The only difficulty is the hardness of the slag, but this is overcome by Mr. C. Wood's method of running it into water, when it disintegrates, and yields a slag sand, which is easily ground with the chalk after separation of a little entangled iron by sifting. Attempts have long since been made to produce this cement in the ordinary kiln, but have been abandoned, as the mixture has no coherence, and the lumps fell to pieces as soon as they got hot, and choked up the draught, putting the fire out.

"This friability, disastrous in the kiln, is no defect, but rather a virtue in the revolver, so that in this matter

the two inventions supplement each other, and the revolver thus brings a new cement material to the fore. It must, of course, be understood that slag cement cannot be made to compete with chalk-clay cement except in the neighborhood of iron-works. In the south of England the cost of carriage of the slag prevents it from being used, as clay is to be had on the spot. There is, however, every reason to believe that the slag cement may prove a profitable manufacture in the iron districts where the cement revolvers could themselves be fired by means of the blast-furnace gases, which are now everywhere being utilized as fuel.

"Careful tests of the new material have been made, from which it would appear that slag cement attains its strength more rapidly than does ordinary Portland, for it was found that Ransome's had a breaking strain of 1,440 pounds on an area of $2\frac{1}{4}$ square inches in twenty-eight days, while the Portland reached 1,325 pounds only in two years. The result is even more striking if short periods are taken, as the following shows:

Days.	Portland, $2\frac{1}{4}$ square inch area, 123 lbs. per bushel.	Ransome's slag cement, $2\frac{1}{4}$ square inch area, 129 lbs. per bushel.
	lbs.	lbs.*
2	510	740
3	608	870
7	818	1,170

* These tests were published in *Engineering* September 12, 1879.

"It is therefore evident that this process is well worth the attention of cement makers in our iron districts, while the revolver process of burning must before long come into universal use."

The method of burning mentioned as the "revolver" process is one of Mr. Ransome's inventions now attracting general attention among cement makers, and it will be sufficiently described here by the statement that it consists in heating the cement slurry crushed to a coarse powder in a revolving furnace, through which it passes in a continuous stream. The friability of the mixture of ground slag and chalk is thus an advantage, and not an objection, as is the case when kiln burning is in use.

The tests quoted were made upwards of seven years ago, and Mr. Ransome has in his possession slag cement made by his process that has been exposed on buildings for years, and yet compares favorably with Portland, and certainly cannot be scraped away with a knife. The test of time—not quite for ten years—it is true, is here offered, and the results are such as to demand the attention of ironmasters anxious to utilize a waste product. Fuller details of the "revolver" process may be seen, by any one interested, in the number of the *Engineer* mentioned above.

TESTING BERLIN'S WATER-SUPPLY.

THE testing of the Berlin water-supply is described in a recent number of the *Zeitschrift für Hygiene*. The cleansing of the water is done by the two large filtering works, one at Stralaw and one at Tegel. The water daily filtered is between 62,000 and 87,000 cub. m. The hygienic investigation of the water is done by the Hygienical Institute every Tuesday. Five tests are made at the water-works, two each from Stralaw and Tegel and one from the reservoir at Charlottenburg. At Stralaw and Tegel one test is made from the unfiltered water and one from the filtered. Five other tests are made with water taken always from the same places in the city. The preliminary tests of the water are made for clearness, color, taste, and smell. The chemical tests are for sediment, chlorine, chalk, and oxidation of the water. Qualitative tests are also made for sulphur, iron, hydrosulphuric, nitrate, and ammonia. Professor Robert Koch's test for bacteria is used. Water that contains harmless bacteria is allowed to be used, when it does not contain over 300 micro-organisms per cubic centimetre.

PAVEMENTS AND STREET RAILROADS. No. XVIII.

(Continued from page 520.)

WOOD PAVEMENT IN THE METROPOLIS.*

THE DISCUSSION.

MR. E. A. COWPER agreed that if blocks were creosoted at all they should be thoroughly saturated with creosote. It had been stated that the author had not dealt with London streets where there was a very heavy traffic, but he had actually given the first cost and maintenance of the pavement in Ludgate Hill, Aldersgate Street, Leadenhall Street, Fleet Street, and Oxford Street.

Mr. G. Allan did not think that wood pavement was a material to be recommended for further extension in the

metropolis. About fifteen years ago his attention was first directed to the question when the Val de Travers asphalt was brought before him. He first had it experimented upon in Bombay, where it was used to pave the footpaths of a number of leading thoroughfares, and it was in consequence of its success that he became the founder of the Val de Travers Co., and had the material introduced for the first time in London, their first contract being for Cheapside. When that contract was being carried out, Portland cement was used for the first time on an extensive scale. Lime was proposed, but upon his recommendation Portland cement was substituted in the contract, at an increased cost to the company of £4,000. No doubt it was to the excellence of that concrete foundation that the success of the asphalt was due. Wood should be regarded as simply a temporary material for paving; so perishable an article should not be thought of for a moment for permanent use. As granite sets had given place to wood, so wood would have to give place to an impervious material, as asphalt, or some future improvement upon it. Both frost and sunshine had a very destructive action upon wood, or any material of an absorbent nature, but asphalt had no absorbent qualities, so that whatever wet might fall upon it it was rapidly dried up by the atmosphere. The reason why the use of asphalt had not rapidly extended was owing to the inefficient arrangements of the metropolis. These had no doubt been improved of late years, but not sufficiently to justify vestries and other authorities in a further extension of asphalt. Asphalt pavement should be washed every morning as regularly as a stable or kitchen floor, and sanded if necessary, according to the state of the weather. If that were done, he believed asphalt would be everywhere demanded. In the case of wood sets there was nearly double the joint area of granite sets, and the joints were simply receptacles for dirt, mud, and horse droppings, which in dry weather were discharged in the form of dust. In asphalt there were no joints, and nothing to receive the droppings. All the dirt lay upon the surface, ready to be washed or swept away.

Mr. G. H. Stayton, in reply, said he had been glad to hear the various points discussed, particularly the criticisms of Mr. Isaacs; but he regretted the course he had taken, feeling convinced that his conclusions were wrong, especially as to cost, economy, and further extension. With regard to the question of absorption, he would only call attention to a block which had been four or five years in actual use in King's Road. It had been taken up from the centre of the road, and it showed clearly that the absorption had been practically nil. His experience had been that if the wood was sound there was no fear whatever of decay from absorption up to a certain point. He had no personal knowledge of the system of wood pavement referred to by Mr. Lawford as having been laid in 1841, neither had he ascertained the cause of its failure. The chief object of the paper was to draw attention to the modern system, as from its unprecedented extension within the last few years more advantage might be gained by a consideration of its merits than by going back a period of forty-three years. The remarks of Mr. Weaver were valuable from his great practical experience in the question, and considerable weight might be attached to his opinions thereon. It was satisfactory to note that he concurred with the author as to the advantages of the plain system, and the necessity for great care in the use of wood, but a few points demanded correction. In the first place it was to be regretted that Mr. Weaver should have fallen into the error of remarking that one of the author's statements was "that wood pavement was laid down better and cheaper in Chelsea than in any other part of London." The statements advanced in the paper did not in the least justify any such conclusion. He merely asserted that the Chelsea pavements comprised all the essentials of a sound and economical pavement, and that the result had been eminently satisfactory; but he readily admitted that the Improved Wood Pavement Company, Henson's Company, Messrs. Mowlem & Company, and Messrs. Nowell & Robson, had also carried out extremely good and creditable work. The net cost of the Chelsea pavement in Fulham Road was rightly stated to have been 10d. per square yard more than the Kensington part, but Mr. Weaver was in error in asserting that the former took forty per cent. longer time to execute. The Chelsea work had been commenced on the 5th of September, 1881, and was completed, and the road reopened, on the 15th of November, thus giving 149 square yards per diem as the result, whilst the Kensington work was carried on in two sections between the 28th of August and the 21st of October, giving 143 square yards per diem for each section. The Kensington pavement had a large proportion of old macadam in the concrete, and the system of blocking, which he considered objectionable, had been adopted; and there was little question that the cost would eventually be as great as that of the Chelsea pavement. The wood-paving works, executed in Chelsea in 1879 by the board's own staff, saved the ratepayers £3,160, which fact proved that the system might be attended with substantial advantages. Mr. Weaver's remark as to the difficulty of organizing an efficient staff was, in his experience, purely imaginary. The conclusion that when the cost of macadam exceeded 1s. 6d. per square yard per annum it was time to adopt wood, fully bore out the author's view, inasmuch as the 2s. 2d. mentioned in the first proposition included 8d. for cleansing, thus leaving 1s. 6d. for repairs only. Notwithstanding what Mr. Weaver had urged against the use of studs, the author's practical experience satisfied him that they were preferable to laths, as he had repeatedly seen considerable displacement of

blocks, and irregular width of joints, where laths had been adopted. The statements of Mr. Isaacs were fallacious and misleading. He challenged the accuracy of the author's conclusions, but failed to refute them by adducing a single reliable fact or figure as to annual cost of former or present maintenance, or records of traffic-weight, in justification of the position he had assumed. In a previous discussion in 1879, on street carriageway pavements, he also made certain statements at which Mr. Howarth expressed considerable surprise when correcting them. Mr. Isaacs must either have paid no attention to the paper and tables attached thereto, or he must have neglected to formulate statistics as to weight of traffic and cost in his district, otherwise he could scarcely have made statements which had no practical value. Mr. Isaacs contended that London traffic, in the strict sense of the term, might be seen in the Holborn district, but not in the districts of Chelsea or Kensington. To a certain extent this was correct, but subject to qualification. In Holborn itself the daily maximum traffic-weight per yard width was approximately 1,100 tons, in Brompton Road it was 648 tons, and in King's Road 603 tons. The author made due allowance for the variation in the traffic-weight in preparing the traffic table, from which it might be assumed that the annual cost of the wood-paving in Holborn, if spread over a period of fifteen years, would be 2s. per yard, besides cleansing and sanding 5d., or a total of 2s. 5d. Mr. Isaacs had made no attempt to supply figures upon this point, and without such information it could only be assumed that he had not given full attention to the subject. He had apparently intended to show that the experience of Mr. Weaver and the author was such that their opinions upon wood pavements with "London traffic" ought not to be indorsed, but he failed to adduce any serviceable information in opposition to those opinions. It might, therefore, be assumed that he had taken no pains to make himself acquainted with the statistics relating to his experience, which would certainly have been an easy matter in so small a district as Holborn, which had but fifteen miles of streets (of which three-fourths of a mile were macadamized, and 16,000 square yards were wood), whereas in Chelsea and Kensington combined there were 108 miles of streets, of which forty-one miles were macadamized, and 217,000 square yards were wood. But apart from this, the paper dealt with pavements subjected to "London traffic" in its broadest sense. Several instances were given in which the actual life of block had exceeded seven years, notwithstanding that the daily traffic-weight was upwards of 1,000 tons per yard width. Mr. Isaacs was evidently under a misapprehension as to the meaning of the item of 2s. 2d. per yard in the first proposition, as he deducted the 11d. for cleansing from 2s. 2d., instead of 2s. 10d., as explained previously, and in the foregoing reply to Mr. Weaver's remarks. The first proposition was, "That where the ascertained annual cost of maintaining and cleansing a macadamized carriageway exceeds 2s. 2d. per square yard * * * the substitution of wood is desirable." The figures (2s. 2d.) were arrived at by working out the cost of wood pavement, including first cost, interest on loans, repairs, renewals, and cleansing, for a period of fifteen years, in the following manner—viz.:

	s.	d.
First cost.....	10	6
Repairs.....	0	4
Renewals of blocks every seven years.....	12	8
Interest on loans.....	2	5
	25	11
Per annum.....	1	8½
Add cleansing and sanding.....	0	5
Total.....	2	1¾

If, therefore, the author's experience was of any practical value, he was satisfied that wood was undoubtedly a desirable and economical pavement as compared with macadam under the above-named circumstances. The observations of Mr. Rich respecting traction confirmed the statement in the paper as to the low resistance of wood pavement to traction. The author had not used the new dynamometer belonging to the Metropolitan Board of Works, but as regarded the average distance that a horse might be expected to travel without falling, Mr. W. Haywood, M. Inst. C. E., reported in 1874 that on granite it was 132 miles, on asphalt 191 miles, and on wood 446 miles, whilst the injuries to horses and obstructions to traffic were greatest on asphalt and least on wood. Mr. Matheson's remark that in many respects asphalt was better than wood coincided with the author's views which also explained why the consideration of asphalt had been excluded from the paper. Within the last month the entire carriageway of a street under the author's charge had been paved by the French Asphalt Company, this system of pavement having been adopted principally on sanitary grounds. The author did not agree with Mr. Allan that wood was likely to be superseded by asphalt, at any rate in the principal West End thoroughfares, unless the reputation of the former became damaged in consequence of their neglect, as described under the head of management. Obviously, both wood and asphalt needed constant attention in the matter of washing, cleansing, and sanding; but however suitable asphalt might be for footways, the author could only repeat, that nothing but downright neglect in the management of wood was likely to lead to its extension, on account of slipperiness and the cruelty to horses which its adoption entailed. Mr. Giles and Mr. Boulton made some remarks pertinent to creosoting. The author in no way desired to do injustice to the system, his experience of creosoted piles having been favor-

* A paper by George Henry Stayton, Assoc. M. Inst. C. E., and printed in the Minutes of the Proceedings.

able; but however desirable in theory it might be to creosote wood-pavement blocks, his experience did not convince him that it was good in practice. Some few years since he had seen wood pavement taken up at Westminster, where creosoted blocks had been used. Many of the blocks were internally as rotten as touchwood, and the sappy blocks had worn down greatly under the pressure of traffic. It was difficult to see that any advantage or economy could be gained by the adoption of creosote, and the author was strongly of opinion that the surface of blocks gorged at the rate of 10 or 12 pounds per cubic foot, would become so slippery, and the jointing so unsatisfactory, that the system would create dissatisfaction.

(TO BE CONTINUED.)

DOMESTIC ENGINEERING, ETC., IN THE
EQUITABLE LIFE INSURANCE BUILD-
ING, NEW YORK CITY.

No. VI.*

(Continued from page 650.)
PNEUMATIC SERVICE.

THE building is supplied throughout with a very complete pneumatic service, which was furnished and put in place by Charles Wolff, of Nos. 3 and 7 Rector Street, New York. The service is divided into three distinct systems, each working with different degrees of vacuum.

First.—The "general" system, for the exclusive use of the officers of the Equitable Life Assurance Society, whose offices are all located on the second floor. This system includes the following offices: president; first and second vice-presidents; comptrollers; cashiers; book-keepers' department; medical department; actuary's department; actuary's room; room of the President of the Mercantile Trust Company; president's private office in the tower; Mercantile Trust Company; Mercantile Safe Deposit Company; the law office of the company's counsel on sixth floor; the engineers' department; supply department; also a connection between this and the "central" system. This system is operated by the No. 5 Root blower, shown in cellar plan at J, the vacuum required being equivalent to three to four pounds.

Second.—The "central" system, which includes one line to each of the six floors above the "Equitable," or second, floor. This part of the service differs from the Equitable system in making all deliveries to a delivering station located at a convenient point on each of the various floors, instead of directly into each office. Messages are received and delivered by two hall-boys stationed on each floor for that purpose.

This system also includes a line of tubes from the kitchen—located on the top floor—to the restaurant on the ground floor; also a line to the Lawyers' Club, another to the Insurance Club; also a line to the central station. The vacuum required for this part of the system is equivalent to from four to five pounds, and is supplied by the No. 4 Root blower, marked K on cellar plan.

Third.—The "high-pressure" system, which includes a line from the central system to the U. S. Signal Service offices located on the highest point of the building, overlooking the New York Bay, with facilities for connecting with the Western Union underground system, whose pipes run directly into the building.

The vacuum for this system is furnished by a Knowles double-cylinder vacuum-pump, shown in cellar plan at L. The vacuum required for this service is seven to eight pounds.

In addition to these well-defined systems, there are a few independent lines, including one from the Western National Bank (in the building) to "central station," from there to the underground silver vaults and the offices of the Mercantile Safe Deposit Company.

METHOD OF OPERATION.

An explanation of the manner in which messages are sent by this service may not be out of place. A complete understanding of the principle upon which the carriers

containing the written messages are sent from place to place and back may be had by studying Fig. 8. Box A is one of a series at a "central station;" Box B may be located at any distant point; pipe C is connected to blower, hence there is a vacuum in both boxes, causing air to enter at D. The carriers are made of leather about six inches long, and made a loose fit for the tubes, which are of brass, and $2\frac{1}{4}$ inches diameter. It follows, if one of these carriers are dropped in the bell-mouthed tube D it will be deposited in the box B almost instantaneously. The boxes being made nearly or wholly of glass, the package is easily seen by the boy in waiting. He removes it by opening the self-closing and self-sealing door E; he examines the address of the enclosure, and quickly sends it by messenger to its destination. If there is an answer,

FIG. 8.

he encloses it in a carrier, opens door F, and drops it in bell-mouthed tube G, which is located in the box, and immediately it arrives at box A, from which it is withdrawn in the same fashion. It will be clear, from the above explanation, that each element, taken by itself, forms a complete circuit, and that the box B is simply a means of ingress and egress to the circuit, so that if the pipes leading to and from box B were united, as shown by dotted lines, the carrier would pass clear through the box and return to box A without assistance. The circuit is constantly kept intact or in good order by the self-closing and sealing doors in the fronts of the boxes, except at the moment of withdrawing or delivering a message. The above explanation serves to illustrate the whole, each member in the system being but a duplicate of this single element.

A central station, Fig. 9, consists of a number of boxes, A A, being placed side by side, and connected together by

FIG. 9.

short tubes leading to an overhead main, C, that is in direct communication with the blower or vacuum-pump. Fig. 1 (basement plan) illustrates the receiving and dispatching station (central station) of the Equitable system. Its location is on the "Equitable" floor, and just over No. 84, on the cellar plan. From this point radiate valves to the various offices already named. A similar station for the central system is located on the ground floor in a booth off the grand corridor close to the grand stairway, in close proximity to the post-office boxes, Western Union Telegraph offices, District Messenger service, express, railroad, steamship, and theatre ticket offices,

This plant of pneumatic service was put in the building to do away with the usual speaking-tubes, telephoning between offices in the same building, the calling of messenger-boys to carry telegrams, and their consequent running through the building, and to secure privacy, exactness, and dispatch in transmission to be maintained, as every important office is reached by the direct service on the Equitable floor, and in the remainder of the building by means of the hall-boys stationed on each floor for the special purpose of receiving and delivering the messages. It is the largest and most complete of any plant yet erected and has features that are new, among which may be mentioned the building up of central stations by uniting a series of single boxes as shown in Fig. 9, instead of using a large single box into which all the receiving tubes gathered as heretofore.

The advantages are that boxes can be added as the system is extended further than originally intended; also, in case a door in one of the boxes is hard to open on account of the vacuum behind it, then all that is necessary to relieve it is to shut off the quick-closing gate-valve H in the pipe connection between the box and the main, thus "cutting out" that single box without disturbing the others in the circuit.

Another feature applied here that has not been used before is that of carrying an independent vacuum-pipe to a distant part of the building which lies out of the regular route of the tubes. This arrangement makes that particular box a receiving, delivering, and central station all in one, and enables private correspondence being kept up between the two points without passing through the "central" station.

The first 20 feet of tubing leading from blower No. 5 is 16 inches diameter, of No. 4 is 14 inches diameter. The rest of each main is 10 inches diameter, the object being to form a small reservoir near the blower.

The size of the main pipe used for the high-pressure service is 4 inches diameter. The pipes are regular wrought-iron pipe, the 16 and 14 inch pieces being made of galvanized spiral pipe.

The tubes are put out of sight as much as possible, and where they enter the offices they are covered over with a small closet of neat design, on top of which are set the receiving and dispatching boxes.

Figure 10 illustrates one of these boxes set on its mounting. The sides of the boxes are made of solid brass of open-frame pattern polished on the outside. Glass is used as much as possible in the construction. The small doors are hung on hinges furnished with spiral springs to keep

FIG. 10.

them always closed. The joints of the doors are a very neat fit and cushioned with soft rubber. Within each box is a curved guide of grate pattern to guide the carriers to fall where wanted. The method of joining the tubes to the boxes is by inserting their ends into short pieces of tube brazed into the bottom of each box, and whose inside diameter equals the outside diameter of the regular tubes. Beeswax is used in making the joint. The bell-mouth is fitted in the same manner. The joints of tubes throughout the building are soft soldered. All the necessary bends in the tubes require to be of large radius to facilitate the passage of the carriers. The large tubes shown in the cellar plan leading from the blowers connect to 10-inch wrought-iron pipes that go direct to the central stations shown in Fig. 9. The parts of these pipes that are in full view are made of brass tubing.

The boxes were special, and manufactured by the Ashcroft Manufacturing Co. In connection with the pneumatic service is a system of electric wires and call-bells to give notice from the central station to the distant box that a message has been sent. An incidental benefit arising from the use of the system is the extra good ventilation in the neighborhood of the central stations, as the amount of displacement of air by No. 4 blower running at the medium speed of 125 revolutions per minute is 97,500 cubic feet per hour, while No. 5 running at the medium speed of 100 revolutions per minute displaces 138,000 cubic feet in the same time, making a total of 235,500 cubic feet.

(TO BE CONTINUED.)

* No. I. of these articles, containing the first installment of Sketches of Plumbing, appeared in our issue of October 8; No. II., General Description of Building and Plant, October 15; No. III., Details of Pumps and Boilers, October 22; No. IV., Smoke-Stack and Passenger-Elevator Water-Supply, October 29; No. V., The Elevators, November 5.

PLUMBING IN A MADISON AVENUE RESIDENCE.

THE illustrations represent the plumbing work recently completed in Mr. Francis Lynde Stetson's residence at 576 Madison Avenue, New York. The building is a four-story brownstone structure, which is now being remodeled.

The old plumbing has been removed and replaced with new, complete from the sewer. The general features of the pipe system in this house are noteworthy on account of their simplicity and directness. The water-supply pipes

The slop-sinks shown in the butler's pantry and a floor-waste in bath-room on second floor located directly over it have porcelain-lined bottoms and marble sides, the bottom of each being set slightly depressed below the floor. The top of sink in butler's pantry is 6 inches above the floor and is all marble except the bottom, the inner dimensions being 6x16x30 inches. The top slab in front has a width of 4 inches projecting inside the sink one-half an inch. The marble slab shown over it and on butler's sink is paneled on the top and made of one piece.

run direct from kitchen to laundry suspended from the ceiling; thence with a right-angle change in course to the point shown in ceiling of laundry, where it passes through the ceiling and floor, thence in a vertical line (through the hall closets exposed in them and accessible) to a point near the roof of fourth story.

The laundry shown in the illustration is located in rear of basement hall opposite the kitchen; a butler's pantry is on parlor floor; bath-rooms on second, third, and fourth floors in the rear hall-rooms, with a water-closet in each bath-room. The wainscot in the kitchen, butler's pantry, and bath-room on second floor consists of glazed buff tile

*A Bath Room in Residence of
F.L. Stetson Esq. N.Y.*

6x6 inches, with a border in butler's pantry of black walnut, and in bath-room of ornamented tile, and the latter room has a base-board of tile with similar border. The wainscot of the laundry and bath-room on third floor is black walnut and ash; and in bath-room on fourth floor the material is all ash. The bath-tub on second floor is porcelain-lined, with marble top and sides, but the water-closet seat and hip bath are trimmed with maple. The bath-tubs on third and fourth floors are planished copper.

The space over slop-sink has a width of 20½ inches and a length of 27 inches.

The nickel-plated faucets are set 18 inches above bottom of slop-sink, and the end of waste-pipe from floor-waste on second floor is shown near them. The floor-waste on second floor is at end of bath-tub, having a width of 29 inches and length of 24 inches, with bottom nearly flush

Diagram Showing Arrangement of Pipes in Laundry and Kitchen.

with the marble-tiled floor. The faucets are similar to those described on floor below. The waste from floor-waste discharges into the sink below, and then passes through waste-pipe O in laundry.

The flushing cistern for the kitchen closet is secured to wall over laundry tubs.

The cisterns for flushing closets on second and third stories are set on the floor above the closets they flush, between the bath-tubs and closet seats. The closet on fourth floor is flushed from a large tank suspended over it. This tank is 28x56 inches and 20 inches deep, which contains 123 gallons of water. The large or house tank is located in hall closet on fourth floor, and has an entrance to it from the roof. The dimensions of this tank are 3½x5 feet and a height of 7 feet, and will contain 88½ gallons. The

large tank in bath-room on fourth floor, previously described, receives its supply from the overflow of house tank only, which explains its large size, and is intended to furnish a supply for flushing whenever house tank is not kept full, but the flushing-cisterns on the floors below receive their supply from the house tank. The pipe M, shown in laundry, is the overflow-pipe from this house tank, and extends down to cellar, discharging into a sink.

The tell-tale pipe, J, also runs from house tank to the sink in cellar. A gas pumping-engine is located in the cellar; that supplies the house tank with water through the pipe L, and this supply is utilized for a high-pressure system. The low-pressure system comes direct from street supply, and extends only to the second floor, where a cut-off is located to permit the latter to be separated from high-pressure system, if desired, and would be utilized whenever the supply is cut off from the street-main.

The main supply-pipe from the street main is lead, 1¼ inches in diameter, and has two branches near the rear of the cellar—one extending up through the laundry to cut-off on second floor, and is shown at A. This pipe is continued with lead to joint shown under laundry tubs, where a branch is taken from it which extends to butler's pantry, and is indicated at N. All drinking water is supposed to be drawn from the butler's pantry, and, therefore, to obviate any objection that may be made against the use of galvanized-iron pipe for this purpose, a lead pipe is carried to this point. The other branch runs to kitchen and is connected with jacket of grease-trap, shown at B, with a branch from it under kitchen sink connecting with C, and then extends to faucet over sink, and from branch described up into top of outer boiler. The boiler is made of copper and is a double one. The pipe D branches from C and extends up connecting with centre boiler, thence running to laundry and up to house tank. The pipe E is hot supply and runs from centre boiler to laundry, thence up above house tank, with its upper end utilized as relief for excess of air-pressure of boiler. The pipe F runs from faucet over kitchen sink and thence up, connecting with outer boiler, thence to laundry and up to above house tank, and there also becomes a relief pipe. The pipe H extends from kitchen range under boiler, thence down through floor, forming a waste from boiler below the valve near floor, but branches are taken from it and extend up to outer and inner boilers. A third branch G runs up and through laundry to cut-off previously described, and is

utilized as a circulating pipe by a connection through the cut-off with pipe A, and also connecting with high-pressure system through the pipes F and D direct from house tank, but when cut-off is closed connection with high-pressure system ceases. Two check-valves are set in pipes C and D at R to prevent water from high-pressure system from extending into low-pressure system when cut-off on second floor is closed. Soft seat-metal valves are used in place of stop-cocks, above and below the boiler to control the flow. The pipe K, shown in laundry, branches from E on second floor and extends down for hot-water supply to lower slop-sink and butler's pantry. The cold supply for this slop-sink branches from A in laundry. The pipe I in kitchen extends to roof and ventilates the grease-trap. The pipes in laundry indicated by M, L, A and J have a short offset

on second floor to bring them in a vertical line with the pipes coming from boiler.

A 4-inch soil-pipe and a 2-inch vent-pipe extend from cellar to top of house, back of closet-seats at rear end of bath rooms, inclosed in a box above kitchen floor. The safe waste is inclosed with them also.

A sink is located in the cellar, which receives the discharge from all waste-pipes required by plumbing law. The tell-tale and house-tank pipes discharge here also. Mr. John Renehan, of 163 East Thirty-fifth Street, New York, was the master plumber; the work was done in accordance with plans of Mr. Charles F. Wingate, under the direction of Mr. Henry Rutgers Marshall, the architect.

THE WASHINGTON PLUMBING REGULATIONS.

THE Washington *Star* recently reports an interview with one of the Commissioners of the District of Columbia and Plumbing Inspector Robinson, as follows, on the decision of Judge Bingham on validity of certain plumbing regulations noticed in our issue of October 29:

"We thought we had the power to make those regulations," said Commissioner Wheatley to-day, referring to the decision rendered by Chief Justice Bingham, in the Court in General Term yesterday, that the District Commissioners have no power under the law to make regulations for the examination and registration of plumbers.

"We acted upon the advice of our attorney," continued the Commissioner, "who believed we had the power under the law." He considered it of great importance to the health and welfare of the community that such regulations should be made, and it was this reason that inspired our action. A man is not allowed to compound a physician's prescription or to practice medicine without a certificate or diploma, and it is quite as important that the plumbers should be competent to practice a trade or profession that is so intimately connected with the health of the people. The court very reluctantly gave that opinion," continued Mr. Wheatley: "they evidently recognized the fact that some such regulations are necessary." He stated that the commissioners will ask Congress at its next session for the power to do this.

Mr. S. A. Robinson, Inspector of Plumbing, was asked by the *Star* reporter what effect the decision of the court yesterday will have upon his department. Mr. Robinson replied that it does not change or annul the regulations as in force prior to the amendments made by the Commissioners on April 23 last. He said that even as it is the regulations which the court has declared void and illegal have accomplished much good. They have had a beneficial effect upon both the general public and the plumbers, because they have caused men to study and to look on the moral side of the business, and to give the trade an attention they had never before thought of applying to it. Books have been placed in their hands for study, which is something that was never thought of or done before the amendments were made to the regulations by the Commissioners. Mr. Robinson said that the rules caused the plumbers to take a greater interest in their business, and those who have commenced to study and improved themselves will continue the good work. "Why," said he, "I have had apprentices, as well as master plumbers, come to me and ask to be given the names of books to read upon the subject of plumbing."

"What did the trade generally think of the regulations for the examination and registration of plumbers?" asked the reporter.

Mr. Robinson replied that the majority of the plumbers were greatly in favor of their strict enforcement, and were much pleased with their practical working. They believed the regulations would have a tendency to elevate the trade in the minds of the general public, and be the means of improving the condition of business. They also were in a fair way to weed out of the business all those incompetents who bring the trade into disrepute. About ninety master plumbers have been examined, of which number only seventy passed. They are about one hundred and twenty plumbers doing business in the city.

Commissioner Webb telephoned District Attorney Riddle to-day for a certified copy of the opinion. He also asked: "Shall the Commissioners issue permits to open the streets to any bonded plumber?" Mr. Manogue replied for Mr. Riddle that the writ of mandamus did not issue, and that it would be best to refuse permits to Hannan and other unregistered plumbers until the matter is decided or until Mr. Riddle has had a chance to reply.

THE PLUMBERS' SIDE OF IT.

WHY THEY OBJECT TO THE CONTESTED REGULATIONS.

THE objections to the recent plumbing regulations on the part of certain plumbers are thus reported in the Washington *Star* of November 4:

Passing along F Street yesterday a *Star* reporter happened to meet Messrs. C. G. Thorn and E. A. Ridgway, the well-known and old-established plumbers, in conversation together.

"Well, good morning, gentlemen. I am anxious to know if you plumbers and the commissioners have settled your difficulties yet?"

"No, sir; we have not," replied Mr. Ridgway, "and I am of the opinion that the action of the Commissioners

in refusing to grant Mr. Daniel Hannan permits to open streets for the introduction of water and sewers is a great piece of injustice. Why, sir, this man is a veteran in the business. He is one of the most thorough workmen in the business. The District itself, with all its high-salaried employees, has not his equal for thoroughness in street-work. It is always done properly and with dispatch. As to his general house-plumbing, it is always carefully and intelligently performed. Yet they attempt to shut out this man and paralyze his business simply because he won't pass a certain kind of civil-service examination required by them."

"Well, if he is competent, why doesn't he comply with the new additional regulations?"

"My dear sir, it is not a question of competency with Mr. Hannan. Nobody that knows the man and his work would question that in the least. It is purely a question of principle with him. It resolves itself into this, that here is an unreasonable demand, unwarranted by common law and common sense. Why should a plumber pass an examination any more than an architect or builder? The architect is required to submit his plans of a building before he is given a permit; this plan has also the plumbing laid out on it, both being passed upon and indorsed by the building and plumbing inspectors. The matter does not end here, for if it did the houses and plumbing might be built and done entirely different from what the plans call for. There is an official inspection of the work as it progresses, made by the above officers, and it is their duty to see that everything is done in obedience to the regulations governing house building and plumbing. What does the proposed examination amount to? Nothing. It is simply an inquiry into the applicant's knowledge of how plumbing should be done as required by the rules and regulations. Is this knowledge any guarantee that the plumber will do the work as called for by the rules? Will the public health be benefited by the plumber's simply possessing this information and not applying it to the work? Would the health office set loose all the plumbers that have submitted to the examination and passed to do plumbing simply on the theory that as they 'know all about it' they will not require any supervision or inspection? As the house is planned, the house should be built (as far as safety is concerned), and as the plumbing is shown on the plans it should be executed in the house, and it is the duty of the inspectors to see that such is the case. It is here that the competency of the plumber is shown. His actual work is the best evidence of his skill. I will also add that I fully sympathize with, endorse, encourage, and will assist Mr. Hannan in his efforts to defeat these unreasonable rules."

"Then, Mr. Ridgway, you don't intend complying with the last regulations issued?"

"No, sir; I don't. If my age and experience from boyhood, my work and my dealings, are not a sufficient guarantee that I understand my business and I cannot carry it on without submitting to indignities and oppression, or the Commissioners will not allow me to carry it on, I will have no alternative but to close up. This point, however, I shall contest. They will have to show cause, and this they will be unable to do, as my record of twenty-two years, both with the old municipal government and the present one, has been of such a character that they have never had reason for charges against me."

"Mr. Thorn, what is your position in the matter?"

"Well, sir, I fully concur in and indorse the sentiments expressed by Mr. Ridgway. I will add, however, that this is not a fight between the Commissioners and Mr. Hannan alone. I have been denied permits on the same ground as Mr. Hannan—that is, my refusal to comply with the last regulations. Why, sir, these new regulations, that so much fuss has been made about, are the worst kind of bosh. There is nothing good in them. They are merely a hobby of some person or persons. Here are some things they include: 'State age, full name, residence, place of business, whether married or single, past history, experience in the plumbing trade or business, with whom he has worked.' Then an examination of the plumber as to his knowledge of physics and hygiene, the obnoxious and illegal \$3 registration fee, and letters from three disinterested, responsible citizens of the district certifying to the intelligence, good habits, and character of the applicant. Think of such men as Ridgway, Hannan, and other well-known, law-abiding, responsible citizens, being compelled to go out and ask for a certificate of character from people among whom they have lived all their lives! Neither the public nor the public health is benefited by all this nonsense. The house builders and the general public are fully protected by regulations issued in 1882. We are not opposed to nor fighting against the plumbing regulations. We have always cheerfully complied with these rules, and if there has been defective plumbing work done it is because the laws have not been rigidly enforced. The plumber doing defective work is punishable under the law by fine or imprisonment. The Commissioners have all proper redress and authority in their hands, and I am of the opinion that the courts will sustain them in punishing offenders. As Mr. Ridgway says, the plumber's work executed by him should be his passport. If the inspector sees that a workman is not competent and don't understand the principles on which the work should be done, he should have him suspended, while a plumber knowing better and yet doing bad work should be punished and either compelled to do the work properly or be driven out of the trade."

"We do not oppose legal and reasonable regulations for our business, proportionate to what is applied to other business of like kinds. There is no question now between

Mr. Daniel Hannan, Ridgway, or myself, and the plumbing inspector, his assistant, or the health officer. They know that we have always cheerfully co-operated with them and have done our work intelligently and without any annoyance to them. *We are all bonded and registered, and have been since 1882*, as the regulations then required. Why, sir, the old regulations are all right. There was no need of tacking on to them the last foolish amendments. The Commissioners have partly seen their error since the suit in court, as you will notice on reading Captain Symon's report."

"As another objectionable feature, we don't like the composition of this examining board. They are very nice gentlemen personally, but we protest against their sitting in judgment on old and experienced practical plumbers. In fact, we object and are opposed to the whole plan of crediting a kind of professional monopoly in the plumbing business. Why, sir, it would be quite possible for these examiners—I don't say they would do so—to limit the number of plumbers to a choice few."

"We think," said Mr. Ridgway, "that any citizen having the capital and enterprise should be free to engage in plumbing as in other business, and that his lack of special training should not keep him out of it, provided, of course, he employs competent workmen and abides by the rules governing house-plumbing. I may add that the largest plumbing houses in this city to-day are carried on by men who have never worked a day or served any apprenticeship at the business, but it is to be presumed, of course, that they have competent foremen and workmen to attend to the details."

"Considerable is said, I know, about the importance to the public of plumbers' work, not only in houses, but also in excavating the streets for the introduction of water and sewer pipes. The Commissioners, of course, should not grant excavation permits to every irresponsible person that might apply; but certainly this civil service examination is not necessary for such work. The fact is that a deposit of \$10 is required of every plumber, in addition to his other burdens, before he can disturb a pavement, and the cost of relaying the pavement is charged up against that deposit. As to water-mains and sewers, the plumber simply lays the lateral pipes. The District government has always tapped the sewers and water-mains. If there has been any bad work and leakage at those points its own employees, not ours, have been to blame."

"Then, sir," said Mr. Thorn, "articles have been published giving the idea that those who protest against the new regulations are men who would be properly driven out of the trade by their enforcement, and, therefore, are not worthy of attention. Well, here are three of us who protest—Daniel Hannan, whose record goes back to 1857, Ridgway's to 1865, and my own to 1866, irrespective of our time of apprenticeship. If we are incompetent or do bad work, it would have appeared before this, without a schoolboy examination."

"We know there are others just as indignant as we are, but who have taken the easier course of submitting to what they thought wrong rather than engage in a legal contest. As it is, we are the sufferers. Our work is suspended indefinitely."

"The Commissioners, their attorneys, and subordinates seem to be angry because they have not had their own way. They treat the order of the Court with very scant respect and talk about 'keeping up the fight.' If defeated in the courts, they threaten to go to Congress and get additions to their already large authority. Now, we do not covet a 'fight,' but simply to be relieved from exactions which we deem ill-advised, oppressive, unwarranted by existing and, we hope, by any future law."

"We come in contact all the time with the District officers, and would rather be on good terms with them," said Mr. Ridgway, "but not at such a cost as submitting to these new rules would imply. As citizens and business men, we want to be put on a par with others in this community, in being free from hampering restrictions, and being regarded as honest and capable until we act to the contrary."

"These are our views, and you are at liberty to make use of them in any way you seem proper."

Novelties.

Under this heading we propose to describe and illustrate appliances of probable interest to our several classes of readers. The selection will be made without reference to the wishes of agents or patentees, being governed solely by considerations of novelty, ingenuity, and probable interest to readers, and especially the fact that they have not been elsewhere described. As a rule we shall make no comments, and it is to be distinctly understood that a notice does not imply approval. No charge will be made for these notices, and any offer of pay for their insertion will insure their omission. We shall be glad to have our attention called to novelties suitable for this section.

AUTOMATIC FLUSH-TANK.

THE accompanying cut shows an automatic flush-tank, constructed as follows: In a cistern or tank T, is a syphon A, with which is connected a small pipe B. The connection between A and B is made by a "division tee," as known in the trade, having a small projection D. The pipe B has at its top an ordinary plumber's ball-cock F, with lever and float G. The float has inside a piece of small bent pipe H, forming a syphon, and has also openings on the top as shown by the arrows. Its shape is immaterial, as it acts like the ordinary ball-cock float. The tank is filled by a supply-pipe S, choked down to fill the

tank at any interval, from a few minutes to several hours or days. Below the syphon A is an ordinary plumber's trap E, having considerable depth of seal. The tank operates as follows:

Supposing the tank to be empty, the float G will fall to a position indicated by the dotted lines D L, and the ball-cock F will be open. Of course, as water runs into the tank, the float G rises and closes the ball-cock. The trap E becomes sealed as water begins to run over the bend of the syphon A. Then the air in syphon A cannot escape and the water in the tank rises to the water-line W L before syphon A begins to operate. Then water runs into

float G through the syphon H and holes in the cover, the float sinks, the ball-cock opens, the air in the syphon escapes, and syphon becomes charged with water and empties tank T. Air entering (after the discharge of syphon A) through pipe B, prevents partial action of the syphon when the tank is filled again, and the operation goes on indefinitely; the float G having emptied itself through syphon H.

The tank is patented by Mr. David W. Brown, of 11 West One Hundred and Twenty-fifth Street, New York.

E. G. LOVE, Ph.D., Gas Examiner.

THE *Journal of Gas-Lighting, Water-Supply, and Sanitary Improvement* of October 11 contains the following description of a new process for the manufacture of steel, which is stated to combine, as far as practicable, the best features of the Bessemer and Siemens-Martin methods, and to eliminate their defects, that has lately been introduced by Mr. B. H. Thwaite, C. E., of Liverpool, and Mr. A. Stewart, of Bradford. It consists in melting the pig-metal in what is known as a "rapid" cupola, and collecting it in a receiver, from which it is run into a vertical converter, and from thence drawn off in the ladle. In its passage through the converter, the metal is subjected to the blast from the cupola-blower. As soon as the metal is collected in the ladle, the latter is raised from its trunnions and rapidly revolved. Stirrers effectually mix the metal; and the steel is then ready for molds. It will thus be seen that the process is rapid and the plant very simple. The system can be applied to existing open-hearth furnaces, in which case the special converter is placed in the centre over the furnace-roof. The metal is run from the cupola either by means of a runner or a ladle; and in its descent into the open-hearth furnace, it is subjected to annular jets of air from the cupola-blower.

THE WRECK OF THE SENECA FALLS STAND-PIPE.

As THE result of our representative's visit to Seneca Falls, we are able to present our readers with the following facts:

This water-tower was completed the 1st of July last, and from that time until its destruction, October 28, was in constant use. It stood about one mile north-east from the centre of the village.

The pumping-station, about $2\frac{1}{2}$ miles beyond, is equipped with two double-acting pumps, each having a capacity of 1,000,000 gallons per diem.

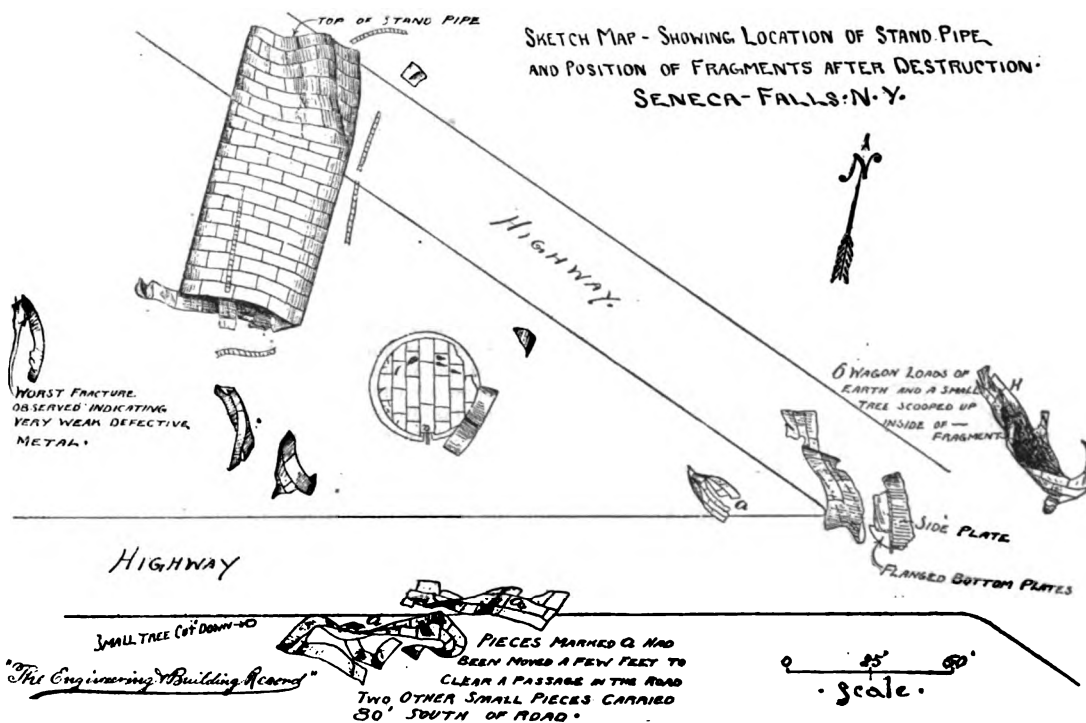

The tank, although not the highest, is said to have had, from its unusual diameter, a greater capacity than any similar one in this country—viz., 630,000 gallons. It was steel throughout and rested on a very shallow rubble foundation. A person present when it was built states that a circular pit two feet deep was dug in the stiff clay soil and the required amount of rough stone dumped in from carts; later, when the masons arrived, the heap was simply raked

over approximately level, and one course of stone laid in Rosendale cement to form the surface for bedding the bottom plates. Upon this platform the bottom plates and first four courses of the tank were riveted up, then they are asserted to have been jacked up and the surface covered three inches thick with Rosendale cement, upon which the tank was lowered. Each course consisted of ten plates 4 feet 8 inches wide, the top of each ring lapped outside the bottom of the next higher. All rivets were $\frac{3}{4}$ -inch diameter and spaced approximately $1\frac{1}{2}$ inches from the edge. All vertical seams were double riveted; the rivet lines were 3 inches apart, and the rivets were staggered and placed 3 inches C. to C. in each line. All horizontal seams were single riveted, the pitch varying from 3 inches for the heavier sheets to $2\frac{1}{4}$ inches for the lighter.

The metal weight of structure was about 270,000 pounds. The total weight sustained by the masonry when the stand-pipe was full was about 5,520,000 pounds. This gives a pressure of about 8,000 pounds per square foot on the foundation.

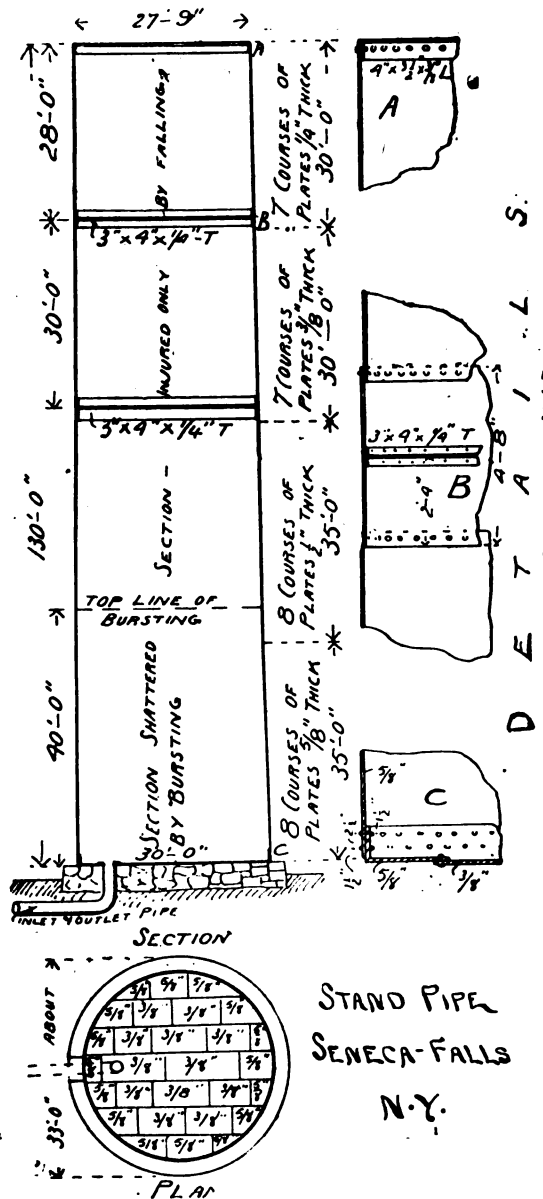

• GENERAL VIEW OF TANK AFTER ACCIDENT • SENECA FALLS • N. Y.

• VIEW OF BODY OF TANK AFTER ACCIDENT • SENECA FALLS • N. Y.

When the stand-pipe was full, the bursting pressure at the bottom was $8,000 \times 30 = 240,000$ pounds, resisted by a section of plate 12 inches high on each side. This gave a strain of 16,000 pounds per square inch of gross section, but the $\frac{1}{8}$ -inch rivet-holes at 3 inches pitch diminished the effective section so as to give a strain of 23,000 pounds per square inch of net section. The maximum shearing strain on the rivets is 25,000 per square inch. The stability against wind pressure, even when empty, was fairly good. An examination after the disaster showed that the steel plates were punched and not reamed; the metal, when tested by chisel and file, was fairly soft. The fractures indicated a coarse, poor grade of steel, in all cases very much underworked, and in some overheated, and an unusual brittleness, with great lack of uniformity. The riveting was excellent.

The foundation masonry appeared very poor and ill-laid, and, where visible through rents in the bottom plate, little or no cement, but considerable dirt, was found.

The burst shattered the lower 40 feet of the stand-pipe, hurling it in 16 principal fragments in every direction; the upper 90-foot section was carried nearly 30 feet clear of the masonry and remained in one piece, considerably flattened. Two whole sheets of the bottom plates were torn out, the disk being moved on the foundation about 5 inches north-east and cut through in five places by violent blows from corners of plates of the falling cylinder.

About three-sevenths of the flange was torn away at the angle, and it showed all round numerous open cracks from 6 inches to 30 inches long. The plates, besides being torn apart at the laps, were greatly shattered, many of them broken across the corner or through the centre, rather more of them in a vertical than horizontal direction. Cracks and gashes extended from 6 inches to 4 feet into the body of the plates from all lines of severed rivet connections. The appearance of all cracks in plates is emphatically not of tearing, but of sharp snapping.

About seven-fifths of the rivets in laps that were torn open were not broken or sheared, and most all the plates, except the flanged bottom ones, tore through the rivet lines. From the projection of the principal fragments to the east

the removal of the top section to the north-west, and the gush of the water south-west, as well as the fracture of one of the smaller fragments found west of the foundation which presented the most defective appearance of any observed, showing very poor, weak metal, it may be surmised that the break commenced on the east side in the third or fourth course or else at a vertical lap just above the flange.

A witness passing within fifty feet of the stand-pipe ten or fifteen minutes before its destruction positively states that the water was then overflowing the top. Manager A. C. Martin, who was in the pumping-house at the time, states that the pressure-gauge indicated only 70 pounds at that point, which he considered equivalent to about 100 feet height in the stand-pipe.

According to the superintendent's statement, the structure was subject to no specifications or inspection of material or workmanship, and was neither designed nor its erection superintended by an engineer.

As stated in our last issue this stand-pipe was built by contractor R. F. Hawkins, Springfield, Mass., for George H. Norman, Boston, Mass., who owns and maintains the water-works plant and receives payment from the town for its use.

SUGGESTIONS FOR A NATIONAL SOCIETY AND OTHER MATTERS.*

TO EXIST, art needs sympathy, and to grow it needs that sort of criticism which ennoble both artist and critic. Therefore, kindly intercourse among architects is useful and should be cultivated; the more because social life both spurs to effort and helps one to keep a check upon his selfishness. A man when tempted may wrong his fellow, but is less likely to when both are of the same society, in which he must endure the reproachful looks and scorn of mutual friends. Members of any organization hate to fall below its average beliefs, no matter what its practice may be.

There is growing need for better training of draughtsmen than our practice now affords, yet there is little chance but in offices for most of these boys to learn. They need schools or lectures, or both; but having neither they fall far below their own possibilities. The work of changing this state of things should be ours. Where there are no technical schools we ought at least to establish some systematic method of training, perhaps by lecturing ourselves, no matter how slight or imperfect results may at first be obtained.

Since the schedule of fees was first printed our methods of work have improved. The amount of drawing alone then done on a given job in the best office would now be regarded as shamefully superficial in the poorest. It costs, not twice, but many times the sum it used, to complete the office work of any building. We are more thorough now and should be paid in proportion.

Our efforts to throw open the Government work to the profession should continue, for the public surely has a right to the talent of its greatest architects, and the profession has a right to the work. Besides, it is a fact that public buildings badly designed depress and injure the artistic sense of the whole people, instead of inspiring to better taste as good ones would. The national structures are the landmarks of our professional horizon; they are most prominent where most men are gathered together, and no one can help but see them. So for good or ill we are all profoundly affected by them.

Statutory revision is necessary, not by Congress alone, but by the Legislatures of every State in which the practice of architecture is not already restricted to licensees possessing competent diplomas, or who have passed examinations before State boards.

But more important than anything yet attempted to be done by any society is the compiling and publishing of a code of ethics for architects, which, of course, shall show what is good, but especially what is professionally damnable in our dealings with each other. Let this be rendered in strong, clear type, and put upon the desk of every one, and it will at once have a most salutary effect upon the fee-cutting, backbiting, backstair-climbing crowd, and remove temptation from the lives of those yet uncorrupted.

As a whole the architectural societies have had plenty of time to show what they can do. But if measured by our hopes or what we have expected, their work has not been satisfactory. We have strength enough, but it has not been brought to bear at the right place and time. No one can doubt that we have tried hard, but taking the entire record we have only won that kind of success most near akin to failure. And now three courses are left to us: To give up entirely, to go on as we are, or to reorganize. The first we cannot think of, the second we are dissatisfied with, and we must look to the last for the only chance to justify continued existence. If the latter way be chosen it is plain that some if not all of the old societies must dissolve and pass away. There have been too many, and their chief faults have possibly arisen from this. Since some must go, to avoid wounded pride or vanity would it not be better for all the old societies to give up their charters and for the members to join together in a single new body where shall be centered all their social activities,

* Abstract of a paper by D. H. Burnham, F. A. I. A., read before the American Institute of Architects at their twenty-first annual convention, held in Chicago, October 20, 1887.

their art discussions and displays, their reform agitations, and finally their full authority? In this case there will be some hope for effective work on the lines of activity proper to architectural associations, and we shall have the chance to finish some of the many things we have commenced.

I do not know, in view of fresh organization, that there is to-day a single society or name to be kept, unless perhaps it be the title "American Institute of Architects," and this only because its dicta are the basis of so many court decisions in every State, and because its name and reputation are incorporated in the records of many foreign societies. This question, however, is for some future committee to deal with. The matter of naming is of little consequence compared to what the constitution and by-laws shall be. If the name of the American Institute or any other society be retained, it must not mean that their organization shall be kept as it is to-day; it must be radically different. The present condition of things is as follows: We have many societies scattered through the country, whose members have the privilege of attending the annual conventions of either one or both the national gatherings. The change should not do away with the system of local societies nor the valuable work they are capable of for the localities in which they are established; but there should be a national controlling body in general things of practice, the members to be elected from the local ones. The annual meetings of an elected body would not be mere pleasant gatherings, no man feeling any particular responsibility, but earnest meetings of those best qualified to act, each one having a sense of responsibility, a clear purpose, and the obligation upon him to do hard work.

A small body of carefully selected men meeting annually for definite purposes, and entrusted with full authority, is what is needed. It is not in the scope of this paper to particularize much about it or its dependent societies, any more than to say that the first should act in matters applying to all architects throughout the country alike, and the latter in matters of social, artistic, and local work. How the local organizations should be formed, where and when the members of the controlling body should be elected, is matter for others to consider.

There should, and undoubtedly will be, a memorial hall, where may be gathered the portraits, busts, and mementoes of our mighty dead, and in which shall be our national archives and library. The only place where this building can be erected without raising local feeling is at Washington, and there it should be.

The office of representative at Washington should be difficult of attainment, and of high honor. I believe the men should be elected for a long term, and that all elections in architectural societies, whether national or local, should be absolutely without nominations being previously made. Men ought to ballot without being prompted or checked by any committee or clique, and it should be cause for expulsion for any man to be found, directly or indirectly, soliciting office for himself, and there should be some penalty attached to his friends doing it for him. The judgment of a society is always best as to who is fitted to serve it, if the men are left to themselves.

A committee should be appointed by this meeting to act with another from the Western Association. These two should be empowered to meet and prepare a plan and recommendation to be submitted for consideration of both bodies in 1888. They should go into the matter of advisability of a complete new organization, and of how it could be brought about; of what, in the main, its form should be; how first elected; how the local bodies might come in and be used; and, finally, should give an outline of the constitution, its work, and the chances for its being successful in the direction we shall want decisive action in.

Correspondence.

All correspondents should send us their names and addresses, not necessarily for publication, but as a guarantee of good faith and because it is often necessary to communicate with them for additional information before printing their communications. Anonymous letters will not be noticed.

PROTECTING WALLS OF BATH CELLS.

NEW YORK, November 5, 1887.

SIR: Your correspondent "Tyro" requests information on some kind of paint for wooden partition walls for bath cells, and I recommend very highly Charlton Enamel Paint, an English production that I have used and had under observation for many years. Russian and Turkish bath-rooms and many hospital wards have been coated with it, and repeated washings with soap and water do not mar its color or gloss.

Yours truly,

HOWARD FLEMING.

THE ARCHITECTURAL LEAGUE OF NEW YORK.

THE Architectural League held its regular monthly meeting at Morelli's on Monday evening last, forty-five members being present.

The most important business was the election of the jury for the coming exhibition. It was decided that the jury should consist of five, three of these being non-members of the league, and all chosen from twenty-five names nominated by the Executive Committee. The jury as selected consists of Richard M. Hunt, Charles F. McKim, Augustus St. Gaudens, non-members; Clarence S. Luce, Edward H. Kendall, members.

Mr. H. O. Avery read a paper on "A Trip through the Valley of the Loire," which was supplemented by some remarks on the same subject by Mr. E. H. Kendall.

THE BURSTING OF THE LITTLE ROCK RESERVOIR.

At noon on Wednesday of last week the new water-works at Little Rock, Ark., were to have been formally opened. About two hours before that time the contractor, Colonel Zeb Ward, accompanied by his son and the watchman, were walking on the wall which divides the upper or settling reservoir from the lower or supply reservoir when Colonel Ward felt the wall giving way. He ran to the outside wall and shouted to his two companions, who barely reached a place of safety when the dividing-wall fell over bodily, liberating some 10,000,000 gallons of water, which flowed into the lower reservoir, and as that was already full, overflowed its walls and poured down the mountain-side in a torrent ten feet deep. Some men and teams were engaged in repairing the road leading to the reservoir; the men escaped, but the teams were ruthlessly tossed about and one is said to have been landed high up in a tree. The buggies of Colonel Ward and his son were swept away, and their horses took fright and have not been heard from since. It is very fortunate that the accident happened when it did, as a large crowd was expected to come out to the opening and Colonel Ward had made preparations to entertain them just below the lower reservoir and directly in the path taken by the escaping waters. The loss of life, had the accident occurred then, might have been very great. The wall that gave way was thirty-five feet high, six feet thick at the top, and twelve feet six inches at the bottom. It was built of stone laid in cement and plastered with a thick coating of the same material, and appeared to be well built, although a small leak was discovered in it the night before the accident.

Colonel Ward has determined to rebuild at once and expects to have everything all right again within six weeks. At the lowest estimate it will cost from \$6,000 to \$7,000 to repair the damage. Some citizens of the town offered to raise a subscription to assist in doing the work, but Colonel Ward declined the offer. The following letter from him will be of interest:

"To the Editor of the *Arkansas Gazette* :

"Allow me to express my heartfelt thanks to our citizens in general for their sympathy so generously extended to me in the misfortune of the loss of the centre wall to the new reservoirs to-day. This is not only a great loss to me, but to the entire city, yet it can be repaired, and while it cost me considerable money and much more hard work, I feel that I am more than paid for it all by its falling as soon as it did and before those invited to be present at 12 M. had arrived, as doubtless many would have been killed or maimed. In conclusion I will say, notwithstanding this great misfortune, the water will be given the city on to-morrow from the new works and continue for the future. Should it not prove as clear as everybody had expected, bear with it for a few months and I assure you it will all come right. Respectfully, ZEB WARD."

NEW LONDON'S WATER-SUPPLY.

From the report of the Water Commissioners of New London, Conn., for the year ending September 1, 1887, we learn that the income for the year was \$23,182, being an increase of about 7 per cent. on the previous year. The expenditures on maintenance account were \$4,087, and on extensions \$5,730. Net cost of works, \$337,308. Population, 13,000. Consumption, 1,100,000 per day.

The rainfall for the year has been heavy, amounting to 53.78 inches, and Lake Konomac, from whence the supply has been drawn, was filled. Trouble was experienced in the spring from a fishy taste in the water lasting from the 20th of May for twenty days. A report from Professor Leeds upon the subject shows that the lake covers an area of 976 acres, and was formed artificially by a dam across the outlet to a natural pond, setting the waters back over grassy land when the lake is full.

The lake or reservoir is divided into two parts by a "filter-dam," which removes a large percentage of the "peaty" color. Examinations made by gelatine peptone cultures showed also that a cubic centimetre from above the filter-dam contained 15,840 microbes, while none were found below, but this was after the bad taste had disappeared.

Professor Leeds recommends a more complete filtration by the addition of more and finer filtering material above the filter-dam, and an improvement of the banks of the lake by cleansing and embankment, so that at no time shall the water at any point be less than 5 feet in depth. A further examination is to be made whenever the bad taste reappears.

The Engineer and Superintendent, Mr. W. H. Richards, reports 40 meters in use, and recommends the substitution

of lead pipe for the cement-lined service-pipe formerly in use.

The use of the water is extending rapidly, and a special report is appended by him, showing, by comparison with other cities, the great waste going on, the supply per tap being 495 gallons and per person 91½ gallons, with but few manufactories or large users. The result is a great loss of pressure at times.

He then enters into a discussion of the various methods for detecting and preventing waste, the reclassification of water-rates, fines, etc.

He states the loss from a common sink-faucet through a ¾-inch pipe 110 feet long running free, to be under 26 pounds pressure 10,512 gallons, and under 68½ pounds pressure 17,280 gallons in 24 hours.

A NEW PAVEMENT.

OUR Milwaukee correspondent sends a newspaper clipping which says: "The North Chicago Rolling Mill Company has completed an order for fifty tons of steel rails, of a peculiar pattern, to be used in paving a block in Chicago. The rails were rolled in the Merchant Mill of the Bay View Works. They are 16 feet 10 inches in length and have a grooved surface on top, to render them rough, so that horses will not slip upon them. The rails will be placed a few inches apart, and the space between will be filled with a patent composition, which is said to be very hard and durable. The pavement is to be used where there is very heavy teaming. If the experiment proves successful it is probable that many of the Chicago business streets will be paved in a like manner."

EXCAVATION BY DYNAMITE.

We take from the *Genie Civil* of October 22 an account of the employment of dynamite for sinking holes in wet ground for foundations. It has been successfully used in building the fortifications around the city of Lyons. The foundations for the walls were to be built in an alluvial soil, constantly inundated by the River Rhone, and composed of shifting sand. It was necessary to sink two metres to find good ground on which to build. Eight cartridges of dynamite, containing each 100 grammes, were exploded together, resulting in a hole 1.10 metres diameter. In this a metal cylinder was sunk, the hole then cleared out, the concrete filled in, and the cylinder withdrawn.

Three points are especially interesting in this matter.

First—The explosion makes a hole shaped like the frustum of a cone, 1.00 to 1.20 metres in diameter, with a depth equal to 75 per cent. of that required on account of the earth falling in.

Second—The explosion compresses the surrounding earth to such a degree that the walls of the hole remain vertical long enough to clean out the hole and put in the concrete.

Third—The water is driven back so far that it does not begin to again filter through the walls for half an hour.

This operation was so expeditious that in a single day of ten hours five holes two metres deep were sunk, cleaned out, and concreted, and the work of laying foundations on them was begun. The foundation was 24 metres long.

In connection with the fatal explosion that happened recently on board a Royal Mail Company's steamer ("The Elbe"), which had just come from the hands of the engineers and was being tried on the measured mile, it may be pointed out that although the Board of Trade requires that the boilers shall be tested by hydraulic pressure to double the working strain, there is absolutely no test insisted upon for the steam-pipes. Nine men were killed by the bursting of one of the steam-pipes, between the boiler and the engine, the place of fracture occurring, not at a bend, but in a straight piece.

OUR exchanges very generally contain a description of the "Newberry-Vantim Chlorination Process" for gold and silver ores. These gentlemen, working together, seem to have adapted and simplified all previous chlorination processes, which have for so long been the hope and, at the same time, the despair of our mining engineers. Want of space does not permit a lengthy description.

ACCORDING to Mr. Graham W. Thompson, of Glasgow, the addition of 0.25 per cent. of alumina to puddled iron increases the ultimate resistance of the iron from 22 to 31 tons to the square inch. This addition also largely increases the elongation before breaking.

STAND-PIPES, WATER-TOWERS, AND THE NORMAN MEDAL.

We suggest that those who contemplate writing a paper the coming year in competition for the Norman Medal take for their subject "Stand-Pipes and Water-Towers."

A NEW oil-well explosive, called "carbonite," is, according to the *Revue Industrielle*, being largely manufactured in Germany. The composition of the explosive is not definitely known, but it has a sandy-looking, plastic appearance. It is exploded with a fulminating cartridge, and is two and one-half times as powerful as ordinary black powder. The explosive action is slow, and consequently the rock is not as badly broken up. Heat, cold, and moisture of the air have no influence on it under ordinary circumstances. The explosions leave no residue, and the gases are harmless. A cartridge of carbonite burns with a blue flame, when placed in the fire, without exploding. When struck with a hammer it explodes, after a short time, at the point struck, but the explosion is not communicated to the rest of the cartridge.

We take the following, in relation to "ozokerite," from the *Revue Industrielle*, according to a recent study made of the mineral by M. Rateau, mining engineer. In its solid form it is fusible at +62° C., and gives, when distilled, benzene, 2 to 8 per cent.; naphtha, 15 to 20 per cent.; paraffine, 36 to 50 per cent.; heavy oils, 15 to 20 per cent.; fixed residue, 10 to 20 per cent. Ozokerite is associated with petroleum; its chemical symbol is C²⁰H⁴⁰, and its elementary composition, 85.7 per cent. carbon and 14.3 per cent. hydrogen. It is soft and plastic, with fibrous breakage, and is for electrical purposes an excellent insulator. It is used for the production of paraffine and white hydrocarbons, the latter having the name of "ceresine." Ozokerite is worth from 550 to 600 francs per ton at the mine. It is only mined in large quantities in Galicia and Moldavia, although found, besides, in the Carpathian Mountains in the Caucasus, and in Utah and Arizona. The annual product is about 25,000 tons.

Iron for October 14 describes an electric whistle or trumpet devised by M. Zigang, which is designed to warn or signal vessels, trains, or tram-cars. It consists of a trumpet tube and a sounding-plate, which is vibrated by the electric current passing through an electro-magnet having its poles close to a soft iron armature carried by the plate. A regulating screw contact, with a platinum point, rests against the iron armature, and serves to interrupt the current of two Leclanche elements as the plate vibrates, thus keeping up the sound as long as desired. The apparatus is simple in construction, and can be used also as a Morse sounder in receiving telegraphic messages, the current being sent through the electro-magnet.

PERSONAL.

HENRY CLAYMEIER has been appointed factory inspector of Milwaukee in the place of Henry Siebers, resigned.

COLONEL HENRY L. ABBOTT has been ordered to proceed from New York to Newport on public business, on the completion of which he will return to his station.

D. J. WHITEMORE, Chief Engineer of the Chicago, Milwaukee, and St. Paul Railroad Company, is in Providence, R. I., where he will act with Joseph M. Wilson, of the Pennsylvania Railroad Company, and A. P. Boller, of New York, as a committee of experts to report a plan for the improvement of the railroad facilities there.

JOHN BOGART, Secretary of the American Society of Civil Engineers, was elected State Engineer of New York State, sharing in the success of the Democratic State ticket last Tuesday.

DR. MOSES GUNN, a physician and surgeon, who had been for a long time in charge of St. Joseph's Hospital in Chicago, died in that city on November 4.

MESSRS. GEORGE W. QUINTARD, Robert L. Cutting, and Thomas B. Musgrave have been appointed a Commission of Appraisal on the proposed Broadway Elevated Railroad in New York City.

CAPTAIN EUGENE GRIFFIN, Engineer Corps, U. S. A., assistant to Colonel William Ludlow, Engineer-Commissioner District of Columbia, has gone to Chicago for the purpose of investigating the underground system of electric conduits.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

WANTED.

CITY OF TORONTO, ONT.

Water-Works Engineer.

NOTICE is hereby given that applications addressed to the undersigned will be received at the Water Works Office, City Hall, Toronto, Ontario, up to 12 o'clock noon, on Monday, the 28th day of November, 1887, for the position of "Chief Engineer" at the Pumping House of the Toronto Water-Works Department. Testimonials to accompany application.
JAMES B. BOUSTEAD,
Chairman Water-Works Committee.
CITY HALL, TORONTO, CANADA, November 7, 1887.

ARCHITECTURAL COMPETITIONS.

MILWAUKEE.—H. P. Schnetzky's plans for the addition to the school building on the corner of Seventh and Prairie Streets for the accommodation of the deaf mutes of the city have been accepted.

BRISTOL, TENN.—Plans and specifications for a hotel, to cost \$50,000, are asked by the Bristol Land Improvement Co.

For works for which proposals are requested see also the "Proposal Column," pages 665-669-671-672-688.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE ENGINEERING & BUILDING RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

WATER. SEWERAGE, ETC.

SPRINGFIELD, ILL.—Our correspondent writes: "There was a special meeting of the City Council in regard to a new water-works system, but they did not do anything. A majority of the Aldermen objected to it, so it was decided to postpone the whole matter until the first meeting in March."

TOPEKA, KAN., proposes to develop her water-power by securing \$300,000 from the city and issuing bonds for \$200,000. The entire \$500,000 to be spent in improvements.

ADRIAN, MICH.—The question of extending the water-supply is being agitated. The Water-Works Company agrees to develop a supply of spring water of half a million gallons daily, with a storage supply of one million gallons, when the city agrees to pay a yearly rental of \$10,000 for 120 hydrants. In the meantime the city is to pay \$250 per month.

ALLEGHENY, PA.—A recent meeting of the Allegheny Water Committee Superintendent Armstrong submitted a report suggesting that a supply of water be obtained from Nine-Mile Island. The river at that point is 260 feet higher than the point from which the present supply is secured. His plan provides for the necessary machinery to pump water into the pipe, when it will flow to the city. The estimated cost is about \$750,000. George A. Cochran favored settling basins. He thought the Superintendent's plan would cost \$1,000,000. C. W. Gerwig thought a settling basin would cost \$3,000,000. He preferred a filtering plant at \$250,000. The filter could be located at Nine-Mile Island. I. R. Sefton thought action should be deferred until they had the analysis of the river water. The subject was referred to the sub-committee on machinery in connection with the Superintendent. The National Filter Company was granted permission to erect a trial plant.

PITTSBURG, PA.—North Versailles and Patton Water Companies have been incorporated.

NEWPORT, R. I.—This city has decided to expend another \$100,000 in sewers.

PIESTONE, MINN.—A special village election is to be held November 14, for the purpose of voting \$20,000 in 6 per cent. bonds to be used for putting in a complete system of water-works in this city.

FARGO, DAK.—A syndicate of Fargo capitalists has recently been organized, with Ald. McHench as President, to bore an artesian well, with the purpose of taking in gas, coal or any other valuable element to be found within 3,000 feet or so of the surface. It is believed that flowing water will be had at from 1,000 to 1,500 feet. The company is to have \$10,000 subscribed before operations are commenced, and its success is somewhat dependent upon the local option vote.

GAYLORD, MICH.—This town will vote, on November 15, on the question of putting in water-works at a cost of \$10,000.

WHITESTONE, L. I.—This town is to be supplied with water from the College Point, L. I., Water-Works. Water mains and fittings, including 20 street hydrants, will be laid at once.

JOLIET, ILL.—This city will receive bids until January 1, for a complete system of water-works. Address John D. Paige, Mayor.

WASHINGTON, D. C.—Proposals will be received by William Ludlow, Engineer Commissioner, D. C., until noon of November 21, for furnishing two 20 inch water-valves, five 12-inch water-valves, two 10-inch water-valves, sixteen 4-inch water-valves, sixteen 3-inch water-valves, and twelve 6-inch three-way-valves.

READING, PA.—The Board of Water-Commissioners are considering the question of enlarging the city's water-supply.

COLUMBUS, O.—Some additional water-mains are to be laid.

HOBOKEN, N. J.—The Pasteur Filter Co. have petitioned the Board of Freeholders for permission to have their filter tried and tested. The matter has been referred to a committee consisting of Messrs. Griffin, McDonough, and Laws.

GRAND HAVEN, MICH.—Application has been made for an injunction to restrain the city from building the public water-works.

MYSTIC, CONN.—A water-works project is on foot.

LEWISTON, ILL.—The Lewiston Water Co. has been incorporated by Lewis W. Ross, A. M. Barrett and others, with a capital stock of \$25,000.

PRINCETON, ILL.—The City Council will receive bids for sinking an artesian well, not less than 5-inch diam. Bidders to furnish their own specifications. Address Mayor or City Clerk.

PLYMOUTH, O.—The people of this place have recently voted to erect a system of water-works.

ALBANY, GEO.—The Albany Water-Works Co. will have a capital stock of \$50,000.

BELLEVILLE, ILL.—In consequence of the recent low stage of the water, the company has directed the engineer to prepare plans for a large storage reservoir and an additional supply.

MANCHESTER, ENGLAND.—Proposals will be received until Nov. 21, by the Water-Works Committee of the corporation of this city for water-meters. Address, T. H. G. Berry, Town Hall, Manchester, England.

SUPERIOR, NEB.—Water-works and electric lights will be introduced here at a joint cost of \$35,000. Address John W. Trier, Civil and Mechanical Engineer, Kansas City, Mo.

WINCHESTER, KY.—Water-works are to be erected here.

MILWAUKEE.—The Cream City Railway Co. has begun work on its Sixth and Thirteenth Ward extension. It will be about three-quarters of a mile long.

COLUMBUS, GEO.—The Board of Trade has taken up the agitation in regard to an improved sewerage system.

VICKSBURG, MISS.—A water-works tunnel 400 feet long is being constructed here.

ORLANDO, CAL.—An irrigation district is proposed. Water to be taken from Stoney Creek.

OSCODA, MICH.—Three thousand dollars has been voted for a well.

GENESEO, ILL., will increase its water-supply. About thirty additional blocks of water-mains will be laid.

MINNEAPOLIS.—City Engineer Rinker, Councilman Mills, and Supervisor Walsh will visit Cleveland, Buffalo, Brooklyn, Philadelphia and New York, to examine water-works pumps.

BAKERSFIELD, CAL.—Our correspondent writes: "A franchise from the Board of Supervisors has been granted to C. L. Kounner, of this place."

HOLRIDGE, NEB.—Plans and specifications are being prepared by A. A. Richardson, Lincoln, Nebraska, for water-works. Estimated cost, \$50,000, on which the city will grant a franchise. There will be about 24,000 feet of pipe, with 57 hydrants. Information will be furnished by addressing A. A. Richardson, the Engineer, Lincoln, Neb. The plans will be ready about Dec. 10.

GREENVILLE, S. C.—A proposition has been made by Julius H. Howard to construct a system of water-works.

KEY WEST, FLA.—A sewerage system is contemplated.

SALISBURY, MD., is to have a system of water-works. Address the Mayor.

DALLAS, TEX.—The plans of J. D. Cook, of Toledo, for a water-supply for this city have been adopted by the City Council. Two reservoirs, costing \$161,000, with a capacity of 50,000,000 gallons each, will be built.

JEFFERSONVILLE, KY.—The contract for the construction of a system of water-works for this city has been awarded to Messrs. S. R. Bullock & Co., of New York City.

HENDERSONVILLE, N. C., is to have a system of water-works costing \$12,000; also sewerage system. For further information address J. D. Davis.

PLYMOUTH, IND.—Address the City Commissioners regarding system of water-works.

HAYWARD, WIS.—Address the Commissioners in regard to a water-works system.

STAUNTON, ILL.—The Board of Village Trustees has ordered a special election, on December 15, for the purpose of raising \$6,000 for water-works.

COLUMBIA, S. C., Nov. 9.—Our correspondent writes: "We have had water-works in our city for fifty years, and are now only enlarging the system by building another reservoir of one and a half million gallons capacity, and the erection of another pump, of one and a half million gallons capacity in twelve hours. The addition is rendered necessary on account of increased demands for water-supply by different manufacturing enterprises now and being established in our city, such as cotton-seed oil mills, cotton factories, shoe and hosiery factories, ice manufactories, etc., and also by the increase in population."

CROSS ROADS, TEX.—It is reported that a water-works system is being constructed by Bryon J. Barry, of Corsicana.

COLUMBIA, S. C.—This city will build additional reservoir, costing \$12,000. Will also erect additional pumping-machinery.

GREENVILLE, TEX.—New bids will probably be called for by the City Council, for building water-works.

GAINESVILLE, TEX.—Messrs. Bell & Myers have contracted to sink an artesian well.

CENTRALIA, ILL.—This city has voted to construct water-works at once. For full information address Mayor B. Haussler.

PENSACOLA, FLA.—The Board of Health officers have appropriated \$15,000 to start the sewerage system as planned by Col. Waring, the engineer of the Memphis system.

BATON ROUGE, LA.—Mr. Miller, of Dubuque, Iowa, is in this city with a view of contracting for building water-works. The City Council will meet to consider such propositions as he may make.

BOUND BROOK, N. J.—This place is to have water-works at an estimated cost of \$20,000.

BRIDGES.

CANTON, OHIO.—The Wrought-Iron Bridge Co., of this city, has been awarded the contract for the construction of a bridge between Verona and Rome, N. Y.

EAU CLAIRE, WIS.—Our correspondent writes: "No bridges are to be built at present, except one iron bridge of two spans, each 100 feet, for which contract is let. Bonds voted to be issued were for the above and two bridges recently constructed."

POTTSVILLE, PA.—Our correspondent writes that no action has been taken towards the construction of a bridge or bridges at Washington Street.

FORT WAYNE, IND.—The County Commissioners have advertised for new proposals for building iron bridge over St. Mary's River at Spy Run Avenue.

COHOES, N. Y.—The contract for the abutments and approaches of the bridge crossing canal at Ship Street has been awarded to John Flood, of Fort Edward. Cost, \$5,781.70.

ROCHESTER, N. Y.—Rochester Bridge and Iron-Works has been awarded the contract for construction of Plymouth Avenue Lift-Bridge, to cost \$16,485. Engineers' estimate was \$16,500.

BROOKLYN, N. Y.—The bridge of the New York and Rockaway Beach Railroad across Jamaica Bay is to be reconstructed.

BEVERLY, MASS.—A petition is in circulation which is to be presented to the County Commissioners praying for a hearing on the project of constructing a bridge across the railroad. The plans contemplate a draw-bridge from Rantoul to River Streets, over the railroad at an expense of \$12,000.

DULUTH, MINN.—The Common Council is considering the proposition for erecting a bridge on Lake Avenue over the railroad crossing.

PINEVILLE, KY.—Address the Pineville Land and Iron Co. in regard to bridge to be built across the Cumberland river.

MEMPHIS, TENN.—A bridge at Monroe Street, costing \$4,000, will be built by the East End Railroad Co. and this city.

TOLEDO, O.—Address R. H. Cochran, of this city, in regard to a bridge to be built over the Ohio River at Martin's Ferry.

RALEIGH, N. C.—Address J. Allen, Chairman Bridge Commissioners in regard to several iron bridges to be built by the Commissioners of Wake Co., N. C.

SUTTERVILLE, PA.—Address W. I. Scott in regard to bridge costing \$50,000, to be constructed over the Youghiogheny at this place.

PITTSBURG, PA.—The Marshall Avenue and Lake Street Bridge, between the cities of Minneapolis and St. Paul, which is being built by the adjoining counties, and the contract for which was a short time ago awarded to the Wrought Iron Bridge Co. of Canton, O., will have a total length of 1,273 feet, made up as follows: East Approach, 19 feet; Shore Span, 95 feet; Tower, 19 feet; Braced Arch, 456 feet; Tower, 19 feet; Braced Arch, 456 feet; Tower, 19 feet; Shore Span, 133 feet; West Approach, 57 feet. Mr. J. S. Sewall is the Chief Engineer, and the work will be manufactured under the supervision of G. W. G. Ferris & Co., Inspecting Engineers, Pittsburg, Pa.

VICTORIA, B. C.—The San Francisco Bridge Co. has been awarded the contract for building a bridge over the Fraser River.

PROPOSALS.

PAVING.—Proposals will be received, until November 30, for paving certain streets. For further particulars address W. M. Owens, City Clerk, Eau Claire, Wis.

BUILDING.—Proposals will be received until December by J. C. Saunders, Arkadelphia, Ark., for building colleges.

BUILDING.—Bids are being received by J. H. B. Adams, Malvern, Ark., for erecting a building, to cost \$35,000.

MASONRY-WORK.—Proposals will be received for grading, trestling, and masonry work of about 100 miles of the Chattanooga, Rome, and Columbus Railroad by J. W. English, President Chattanooga Brick Co., Atlanta, Geo.

BUILDING.—Proposals will be received, until December 15, by W. H. Baldinger, Galveston, Tex., for building Sealy Hospital.

WAXAHACHIE, TEX.—Proposals will be received until November 18 for the construction of six iron bridges by the Commissioners' Court. For further particulars address B. F. Hawkins.

GRADING.—Address R. L. Gorham, President Board Public Works, St. Paul, Minn., until November 17, in regard to grading certain streets.

SEWER.—Proposals will be received until November 17, for constructing a sewer, together with the necessary catch-basins and manholes. For further particulars address R. L. Gorham, President Board Public Works, St. Paul, Minn.

BUILDING.—Proposals will be received until December 5, for the excavation, masonry, and brick-work for one double set of officers' quarters at Fort Clark, Tex. For further particulars address Major A. J. McGonnigle, Chief Quartermaster, U. S. A., San Antonio, Tex.

SIDEWALKS.—Proposals will be received, until November 15, by William Carlyle, Chairman Com. on Works, Toronto, Can., for the construction of sidewalks in various streets.

SAND.—Address the Department of Public Works, 31 Chambers Street, New York City, until April 18, in regard to furnishing 1,200 cubic yards of Cow Bay sand for road surfacing, and also repairing sidewalks.

MISCELLANEOUS.

VICKSBURG, MISS.—Rittenhouse Moore, contractor for dredging in the river here, will begin work in a few days. The work is in charge of Captain William J. Rossell, U. S. A.

TRADE CATALOGUES.

The Chadwick Lead-Works, of Boston, Mass., have sent us their catalogue for 1887. The catalogue illustrates and describes the various sizes and weights of lead pipe and sheet lead manufactured by the firm. In addition, there are also a number of diagrams showing the calibre and outside diameter of the various sizes of lead tubing for various purposes. Also several valuable tables given.

PUBLICATIONS RECEIVED.

REPORT OF THE OPERATIONS of the Sanitary Department of the City of Glasgow for the five years ending May 31, 1887. Peter Fyfe, Sanitary Inspector.

REPORT OF THE COMMITTEE ON DRAINAGE and Water-Supply to the Executive Committee of the Citizens' Association of Chicago, Ill.

REPORT OF THE COMMITTEE ON THEATRES and Public Halls to the Citizens' Association of Chicago.

ANNUAL REPORT OF THE CITIZENS' ASSOCIATION of Chicago, October, 1887.

RULES AND REGULATIONS Governing the Construction of Sewers, Drains, and Plumbing-Work for the City of Amsterdam, N. Y., adopted by the Sewer Commissioners October 11, 1887. William B. Landreth, Constructing Engineer.

RECENT ADVANCES IN ELECTRICITY, Electric-Lighting, Magnetism, Telegraphy, Telephony, etc. Edited by Henry Greer, New York Agent, College of Electrical Engineering.

MANUAL OF THE HEALTH LAWS of the State of Ohio, compiled by the State Board of Health, 1887.

FORTY-FIFTH REPORT to the Legislature of Massachusetts relating to the registry and return of births, marriages, and deaths in the Commonwealth, for the year ending December 31, 1886.

THE ARRANGEMENT AND CONSTRUCTION OF SCHOOL SANATORIA. A paper read before the "Medical Officers of Schools Association," by Charles E. Paget, L. R. C. P., M. R. C. S., London.

SEVENTH ANNUAL REPORT of the State Board of Health of New York. Transmitted to the Legislature, January 19, 1887.

THE SANITARY CODE of the Borough of Asbury Park, N. J. Adopted March 22, 1887. Rules and Regulations of the Board of Health. Henry Mitchell, M. D., President.

Building Intelligence.

We solicit from each and every one of our readers information relating to projected buildings in their locality, and should be glad to receive newspaper clippings and other items of interest.

S s Wyckoff, 525 w Smith, workshop; cost, \$5,000; o, John Davis; a, Stephen Hazzard; b, Bruns & McCann.

221 N 8th, dye works; cost, \$20,000; o, Narwood Bros; a, J F Hunt.

E s Bushwick av, 55 s Melrose st, store and dw; cost, \$8,000; o, Wm P Wagner; a, Th Engelhardt.

ALTERATIONS—BROOKLYN.

S e cor Nostrand av and Floyd st, fr bldg; cost, \$13,500; o, Jacobi & Kelley; a, same.

N w cor Kent av and R'way, br dw; cost, \$7,000; o, Wm Hayward; a, W H Gaylor.

MISCELLANEOUS.

DETROIT.—Grand River, br st; cost, \$25,000; o, J Huff Jones; a, Mason & Rice; b, G Vivier.

72 Adams, br home; cost, \$25,000; o, Working Woman's Home Assoc; a, W G Malcomson; b, Topping & Fisher.

551 Congress, br dwell; cost, \$7,000; o, H Wunsch; a, Donaldson & Meier; b, as above.

Kirby, br school; cost, \$35,000; o, Board of Education; a, R Wallace; b, Jaynes & Son.

120 Trumbull, br dwell; cost, \$7,000; o, S Pierson; a, Spier & Rohns; b, A Hild & Co.

BALTIMORE, MD.—Chester, Chase and Biddle, stone and br factory, 320x60, 2-story, and annex, 320x48; cost, \$40,000 to \$50,000; o, Baxter Electric Manufacturing and Motor Co; a, Benj B Owens; b, B F Bennett.

PHILADELPHIA.—13th s Vine, 2 story br and stone church bldg, 55x77; b, J R Millison.

Rear 224 N 13th, 4 story br factory; b, James W Saunders & Son.

Also 50 2 story dwells.

ST. LOUIS, MO.—DeKalb and Barton, a br factory; cost, \$12,000; o, Pauly Jail Works; b, B Koesters.

JACKSONVILLE, FLA.—Bids are now being received by Mr Miller Drew for the erection of building on Ashley Street.

BUILDING INTELLIGENCE.

MINNEAPOLIS.—Logan av, bet 8th and 10th av N, fr dwell; cost, \$10,000; o, Cobb & McKen.

4th, bet Hennepin & Nicollet av, basement, fire-proof office bldg; cost, \$10,000; o, Globe Printing Co.

18th, bet 6th and 7th av S, 4 br dwells; cost, \$36,000; o, L F Menage.

Park av, near 24th st, fr dwell; cost, \$20,000; o, F W Foreman.

Park av, bet 18th and 19th st, fr dwell; cost, \$22,500; o, Webster & Hart.

Yale place, bet 14th and 15th st, fr dwell; cost, \$8,000; o, J A Page.

W Franklin av, bet Lindley and Pleasant av, stone dwell; cost, \$25,000; o, S. F. Hance.

Cor Lake st and Aldrich av, addn church; cost, \$18,000; o, Congregational Church Society.

Cor 2d st and 11th av S, warehouse; cost, \$19,000; o, Anglo-American Packing Company.

10th st N, bet 1st av and Hawthorne, br store and flat; cost, \$15,000; o, A J Finnegan.

6th, bet Nic and 1st av S, br store and flat; cost, \$45,000; o, F H Peterson.

Pleasant av, bet 22d and 24th sts, frame dwell; cost, \$20,000; o and a, L. F. Groff.

Cor Nic av, and 17th st, br ten; cost, \$75,000; o, E S Buell.

Bet Nic and 1st av S, and bet 1st and 2d sts, br jail, cost, \$25,000; o, city of Minneapolis.

Hen av, bet Harmon Place and Maple, 4 br dwells; cost, \$20,000; o, F. H. Boardman.

CHICAGO.—1013-19 W Jackson, br dw; cost, \$17,000; o, Cassel & Prince; a, J W Cassel; b, Cassel & Co.

2326-28 State, br store and flats; cost, \$14,000; o, Mrs Walker; a, F Baitmann; b, C W Moses.

519-27 Ashland av, brand st church; cost, \$40,000; o, Emanuel Lutheran Church; a, Fred Ahlschlager; b, Wm Schwerin.

731-33 N Ashland av, br storehouse; cost, \$9,000; o, J Wilks Ford.

159-61 Ogden av, br sloop and flats; cost, \$12,000; o, Geo E Stoneham and A E Havens; a, A Smith; b, J O Connell and Tobin & Racraft.

22-24 Scott, br dw; cost, \$17,000; o, Roos; a, H M Hansen; b, M J Benson.

23-29 Quincy, br st and office bldg; cost, \$175,000; o, C C Heisen; a, Jno Duncan.

353 Clybourn av, br store and flats; cost, \$10,000; o, E G Halle and J P Hand; a, Addison & Fiedler; b, Chas Thiele.

676-78 W Jackson, br flats; cost, \$12,000; o, R S Cox; a, C L Stiles; b, J W La Croix.

1181-83 Washington Boul, br flats; cost, \$18,000; o, Simon Foley; a, C A Weary; b, F Guerra & Co.

601-03 N Clark, br store and flats; cost, \$14,000; o, H F Waite; a, W H Drake; b, Connelly & Sons.

431-35 Centre, br dw; cost, \$20,000; o, C W Hansen; a, H R Wilson; b, Jos Hodgson.

3352 Calumet av, br dw; cost, \$10,000; o, Chas J Furst; a, Furst & Rudolph; b, A Beimoldt.

171 Townsend, br flats; cost, \$10,000; o, Landskoog & Friberg; a, Jno Otter; b, And Almer.

3615-17 Prairie av, br dw; cost, \$15,000; o, T S Walker; a, Sargent; b, F S Walker.

3429-35 Park av, br dw; cost, \$24,000; o, Welce & Lowden; a, Beman & Parmenter; b, Walter Ellis.

779-89 Loomis, br office and factory; cost, \$12,000; o, Maxwell Bros; a, Lutken & Thiessen; b, T Tobiasson & Co.

MILWAUKEE, WIS.—Ogden st bet Market and E Water, br blk of stores; cost, \$10,000; o, Peter Schmidt; b, J. Gneisler.

Cherry st nr 5th, boiler house; cost, \$10,000; o, J Obermann; b, C Schleusted & Son.

17 bldgs less than \$7,000.

WEST BAY CITY, MICH.—The Michigan Central Railroad will build a new depot at this place; cost, \$15,000.

BUILDING INTELLIGENCE.

BERGEN POINT, N. J.—The New Jersey Athletic Club has purchased ten acres of land, costing \$30,000, on Newark Bay, on which they will erect club and boat houses.

HARRISBURG, PA.—No new work to report this week of a value over \$7,000; quite a number of houses going up of a value from \$2,000 to \$5,000.

In progress, new Telegram bldg for the Sunday Telegram Publishing Co; A Hughes, builder.

Residence of Wm M Donaldson; a, Smith & Warner.

Residence of J H Bohn; a, same as above.

Nearing completion, residence of James Russ; a, same as above.

STEELTON, PA.—In progress, new school bldg; a, Smith & Warner.

Foundation nearly completed for fire engine house; same architects.

AVONDALE, ALA.—The Birmingham Flouring Co. will put in a 70-horse power engine and boiler, planers, molders, etc., to increase their plant to four times its present capacity. A building for storage purposes will also be erected and a dry kiln with a capacity of 40,000 feet.

LOS ANGELES, CAL., is to have a \$50,000 hospital.

WEST SUPERIOR, WIS., is receiving bids for a \$10,000 school-house.

PHILIPSBURG, KAN., contemplates the erection of a hotel to cost \$10,000.

ALLEGHENY, PA.—No bldgs this week over \$7,000 in value.

PASADENA, CAL.—Pasadena av and California, green sandstone foundation and base, fr dwell; cost, \$45,000; o, Colonel Markham; a, Butterworth; b, Geo D Webster.

The Grand Opera House, cor California Street and Raymond Avenue, is mostly finished by the contractor for the exterior. It is expected to be finished by January 1, 1888.

WEST BAY CITY, MICH.—The Michigan Central Railroad will build a depot here at a cost of \$5,000.

LOS ANGELES, CAL.—The corner stone of a female college has been laid.

MACON, ILL.—It is expected that the project to erect a new county court-house may fall through. It is found that the \$55,000 to be raised by a 75-cent tax limit will not pay the cost of building this year. The question will probably be submitted to a vote of the people in 1888.

ST. PAUL, MINN.—Chicago av, nr Custer, 2 story market and dwell; cost, \$19,000; o, Anglo-American Provision Co.

60 minor permits, \$48,000.

DAYTON, O.—Nothing new over \$7,000.

BAKERFIELD, CAL.—The Grand Lodge of Masons of the State of California laid the corner stone of their new Masonic Temple at this place on the 1st inst.

PALESTINE, TEX., is to have a public school house bldg costing \$25,000. Fifty bonds of \$500 each will be issued shortly.

WEST SUPERIOR, MINN.—The Land and River Improvement Co. will erect a \$100,000 hotel.

MINNEAPOLIS.—W H Dennis has completed plans for the \$25,000 bldg to be built by H A Towne, on 1st av. The lower stories are to be of red granite, with stone and ornamental brick above.

Sidle, Fletcher & Holmes have taken out a permit to build an 8-story stone elevator adjoining the Northwestern mill at a cost of \$50,000.

BOSTON.—Haviland, near W Chester Park, brick apart; cost, \$38,000; o, a, and b, W. E. O'Sullivan.

159 West Broadway, br dwells; cost, \$11,000; o, C Loemans; a, J G Lafield; b, H B Rankin.

CHATTANOOGA, TENN.—Large broom factory on Market st; o, Fred E Champion.

BENTON HARBOR, MICH.—Large oil storage house; o, Cooper, Wells & Co.

JACKSONVILLE, ALA.—The Jacksonville Hotel Company was incorporated October 31, and all the stock subscribed. It is the intention to erect a hotel to cost about \$90,000.

LA CROSSE, WIS.—Federal bldg here; contracts to be awarded next month; cost, \$150,000.

OSWEGO, KAN., is building a young ladies' college costing \$15,000.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1887, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 16. }
NUMBER 25. } PUBLISHED EVERY SATURDAY.

NEW YORK, NOVEMBER 19, 1887.

LONDON, DECEMBER 3, 1887.

SINGLE COPIES, TEN CENTS.
Subscription, \$4.00 per year in advance, post paid. } IN AMERICA
SINGLE COPIES, SIXPENCE.
Subscription, 20s. per annum in advance, post paid. } IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD,
conducted by HENRY C. MEYER, is published every Saturday at 82 & 84 Fulton Street, New York. (P. O. Box 3037).
Its opinions upon all technical subjects are either prepared or revised by specialists.

TERMS, \$4 PER YEAR, IN ADVANCE.

Postage Paid.

OFFICE IN GREAT BRITAIN,

95 & 97 FLEET ST., LONDON.

TERMS, 20s. PER YEAR, IN ADVANCE. Postage Paid.

SINGLE COPIES, SIXPENCE.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York), and crossed ——— & Co.

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzig, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, \$5; China, Japan, Sandwich Islands, Mexico and Cuba, \$5; South America, \$5. The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us promptly of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

LESSONS FROM THE RECENT WATER-WORKS DISASTERS.

WE have constantly urged upon those who have charge of the expenditure of funds for the construction of engineering works, whether public or private, the necessity for providing for skilled superintendence of such works from the beginning of their design to the conclusion of their construction.

Our words have sometimes been heeded, but more frequently have, we regret to say, fallen on heedless or unwilling ears. In the present extraordinary development of water-works construction, the neglect of this essential prerequisite to safety has been very marked, and we have been confidently expecting the collapse of many of the "tin-pan" works which have been built by ignorant and incompetent men under contracts or franchises granted by ignorant and careless officials, in which no provision has been made for inspection of the work in any way from beginning to end. We did not anticipate, however, that in a single day three such striking illustrations of the folly, not to say criminality, of such conduct would be simultaneously afforded as the bursting of the Little Rock reservoir, the collapse of the Seneca Falls stand-pipe, and the fall of the Franklin water-tower.

In the Little Rock case, the catastrophe was nothing more than any sensible man who knew the principles of hydraulics and the practice of good masonry construction would have predicted. The whole matter was absurd. But in the case of the water-towers which gave way, the conditions were such that a combination of knave and fool would have seemed to be essential to produce the result which took place. But, then, everybody knows that that combination did not exist in these cases. The towers were both built and owned by a person who erected them as a business enterprise, to maintain and draw a revenue from. He had had many other similar works built, and there was no inducement for him to either put in bad material or slight the workmanship. But he did not take the pains to find out whether the work he ordered was done scientifically or safely. Mr. Norman makes no claim, we believe, to either technical knowledge or practical skill, and he evidently has not, up to this time, appreciated the value of these two essentials to good design and construction. We hope that this will be a lesson to him and that he will hereafter, when he has an important construction to build, see to it first that the material is good, and next that it is not subjected to strains which it cannot bear.

Whatever may have been the immediate cause of these disasters, there is no question but that the work was designed and executed without any competent engineering advice, and there is almost as little question that had such advice been taken in season, all these structures would be standing intact and useful to-day, instead of lying shapeless wrecks in the midst of disappointed and disgusted communities.

No class of work requires more faithful execution than that which is to sustain a fluid mass.

The important question now is, How is the public to be protected against accidents of this character? The public officials who grant franchises to private individuals or corporations should require works which may affect the public safety to be inspected and approved, both as to design and execution, by competent civil engi-

neers. If they will not do this of their own accord they should be compelled to do so by legislation.

It would be a good plan for every State to provide for such inspection by a civil engineer of recognized standing in his profession and experience in hydraulic design and construction, a stipulated fee to be paid for the service. With such supervision, blunders which are so near being crimes as those at Little Rock, Seneca Falls, and Franklin would not be likely to occur.

THE AMERICAN PUBLIC HEALTH ASSOCIATION AND NATIONAL QUARANTINE.

THE meeting of the American Public Health Association in Memphis, Tenn., November 8-11, was a fairly large and representative one, showing that the interest in its work continues on the part of the older members, while the large number of new members elected is a hopeful sign of growth and progress. The place of meeting is one of special interest to American sanitarians, because of its peculiar connection with the last great outbreak of yellow fever in this country in 1878-9, and because of the results which have followed efforts at municipal improvement in it. Some of these results, as stated in the address of welcome to the association by Mr. Clapp, are, that instead of the nine miles of decaying wood pavement of 1879, the city now has 25 miles of good stone and gravel pavement; instead of four miles of defective private sewers, it has 45 miles of well-laid pipe sewers, with a corresponding series of pipes for soil-drainage; instead of a death-rate of 35 per thousand, it has a death-rate of under 20; its population has nearly doubled, and its trade has more than doubled. But while these gratifying results are largely due to local effort, they are not wholly so. If yellow fever had not been kept out of New Orleans and the lower part of the Mississippi Valley for the last eight years by quarantine and sanitary inspection the history of Memphis might have been a very different one. It was, therefore, proper and timely that the President of the Association, Dr. George M. Sternberg, U. S. A., in his address, should, as he did, devote considerable space to quarantine questions and urge the need for a uniform and satisfactory system of dealing with imported pestilence at all our ports. His views are those which this journal has advocated for the last six years—namely, that we should have a National Bureau of Public Health, with a Commissioner at its head. In connection with this bureau, he thinks that there should be an advisory Board of Health, without executive power, composed of the Presidents of State Boards of Health and of the Surgeon-Generals of the Army, Navy, and Marine Hospital Service. The composition of such a board is a matter of secondary importance: the main thing is to have a central bureau under a single head and provided with ample means for the work which it ought to do.

One of the chief reasons for a quarantine system under national direction alluded to by Dr. Sternberg is the fact that it is not just or expedient that the cost of a particular quarantine station should be met by a tax on the commerce of that particular port. The service rendered is for the benefit of the whole country, and it should be paid for from the general fund. Moreover, in a system which depends on local fees improper

PRESBYTERIAN CHURCH, OCEANIC, N. J.—CARRIERE & HASTINGS, ARCHITECTS.

THE ENGINEERING & BUILDING RECORD ILLUSTRATED SERIES.

RESIDENCE OF MRS. COWDEN, FAR ROCKAWAY, L. I.

McKIM, MEAD & WHITE, ARCHITECTS.

motives for certain regulations will always be suspected, and sometimes justly so. To establish and maintain a national system of quarantine in spite of the opposition of those who are pecuniarily interested in maintaining the present want of system will require the influence of the commercial interests of the country, for experience has shown that the opinions of sanitary and medical associations on this point have little weight with Congress; but this is no reason why such associations should abandon effort in this direction, and we are very glad to see that the subject was brought up for consideration at the Memphis meeting.

THE NEW YORK CITY HALL ARCHITECTURAL COMPETITION.

We have expressed our disapproval of the scheme to destroy architecturally the present New York City Hall and to wipe out much of the small remnant of City Hall Park, yet since our authorities have instituted a competition for designs, presumably in good faith, and expect to get something of merit, it is proper to discuss the terms of the competition, both as showing their want of appreciation of a good architect's services and in the interest of good architecture. This appreciation is so clearly lacking on the part of Mayor Hewitt and his colleagues that it is fitting to call attention to the very unwise and unfair provisions of their circular invitation to competitors in this important competition.

The proposed buildings—by reason of the extensive and intricate character of their requirements, their peculiar relation to existing buildings, and their probable cost—give rise to a problem whose solution will require most cautious and careful handling.

As a subject for competition it is perhaps the most important we have yet had in this State.

The external treatment of a building which shall bind together two such dissimilar structures as the City Hall and the Court-House appears to be a most hopeless and forlorn subject for a competition.

Let us consider the conditions: The City Hall, in two distinct stories, refined, pure, delicate—a charming Renaissance building; the Court-House, two stories, treated as one by means of a colossal order, coarse, unstudied, ugly—a bastard Renaissance of the most objectionable kind; and, finally, an addition to this latter of a wing designed in a species of Romanesque.

These are the unrelated parts which it is desired to unify by means of a six-storied pile, which—as far as its relation to the present buildings go—could be neither “fish, flesh, nor fowl.”

This, however, is a question for the future.

The matter which we desire to notice at this time is the compensation offered to competitors. The committee offer as prizes for what, in their opinion, is a successful solution of their problem, five varying sums of money aggregating \$15,000; and provide that “the premiated plans shall become the property of the city, and may be used and combined in any manner which the commission may approve,” and “no obligation shall be created by the acceptance of any plan to employ the author thereof as the architect to construct the building.” They also require a specification of such detail that working drawings may be made and an estimate of cost of such nature as to admit of an intelligent modification of plans if desirable.

Let us see if they are offering a fair price for what they hope to receive.

The proposed buildings—for, as far as design goes, there are two of them, totally different in their requirements—cover an area of some 70,000 square feet, and will have a cubic contents of about 8,000,000 cubic feet. Their cost will certainly be not less than six millions of dollars, and in all probability nearer ten.

The accepted rate of commission for preliminary sketches is one per cent., but in work of this magnitude would be put at perhaps one-half of that, though the full rate would not be too

much when it is considered that specifications and a detailed estimate are required. In brief, the committee offer as premiums to five men less than one-half the sum they should properly pay to one, and furthermore take away from each the property right in his drawings.

They require that the City Hall and Court House be measured and drawn; they require fourteen sheets of plans, two of sections, ten of elevations, and two perspectives, in all twenty-eight drawings, beside specifications and estimates, and for this they offer to the first premiated design the sum of five thousand dollars.

Add to this that the authors of such premiated designs are assured that they will not necessarily be employed to execute their designs or even to draw them to larger scale; that when they deliver them to the committee they give up all right and title to them upon the payment of a sum which will hardly pay for the time of draughtsmen employed to make them, and that they may be enlarged, detailed, and carried into execution by the employees of the Department of Public Works.

There is little to console an intending competitor in the consideration of these facts. It is all loss and no gain.

There is no doubt that many men will enter this race—in which there may be no prize—but there is great doubt whether any of even the second rank in the profession will be found among them.

Because some architects demean themselves and their profession by unsightly scrambles for place and preferment, it is no excuse for the Mayor and authorities of this city to treat the profession so meanly and contemptuously as they do in the conditions of this competition. It can only be said that so little inducement is offered that there will be small reason for any one who enters the competition to claim he has been taken advantage of.

THE CHICAGO DRAINAGE COMMISSION.

THE letter of the Chicago Drainage Commission given elsewhere in this issue should interest all persons who, as taxpayers, have to bear the expense of the investigations preliminary to undertaking an important engineering work.

Few persons would fail to recognize the loss incurred by the interruption of work on any important construction. The disorganization or disbandment of the working force, the deterioration of the plant, and the damage by the elements to uncompleted and perhaps unprotected work are too obvious to escape notice. In stopping a half-finished investigation, the loss, though less apparent to the eye, is proportionally even greater in fact, for, as is well said by the Commission in reference to this case, “when the present employees go out they will carry with them a large percentage of the results thus far gained, greatly to the loss of the city, because much of the matter will have to be taken up *de novo*, which can only be prevented by having them complete their unfinished tasks.”

If it is unwise to swap horses while crossing a stream, what shall be said of the man who parts with his horse when half way over expecting to get another later on wherewith to complete the passage.

It is to be hoped that Mayor Roche will reconsider his action, but it is well meantime that Mr. Hering and his colleagues should have so clearly and forcibly remonstrated against it, and it is due to these gentlemen to say that they appear to have no pecuniary interest in the present continuance of the work, but rather the contrary, as Mr. Hering's contract with the city is understood by him to cover the making of a final report.

THE PROPOSED AUSTRIAN TELEPHONE SYSTEM.

THE Austrian official *Gazette* of October 11 states that the Austrian Government proposes inaugurating a system of State telephones, in connection with the post and telegraph offices. The idea is not to establish telephone

stations in towns where private enterprise has already done so. According to the proposed arrangement, the Government will connect any building with the telegraph office for telephonic transmission or reception of letters, cards, telephones, telegrams. One may dictate, for a slight additional charge of two cents, telegrams, letters, cards, etc., through the telephone to the post or telegraph office, for transmission to any part of the world, and they will receive and read the contents of letters, telegrams, etc., to you through the telephone. This new style of message is called “phonogram.” The Government intends to charge according to distance for the installation of the plants or wires to the buildings to be connected.

AMATEUR MUNICIPAL ARCHITECTURE.

UNDER this title the *Record and Guide* criticises the unfortunate scheme of Mayor Hewitt and his colleagues to erect more municipal buildings in the City Hall Park, and very properly says:

“The scheme is absolutely destructive of all repose, all dignity, all beauty. If any architect had submitted it as a solution of the problem how to place a building for the needs of the city on the City Hall Park, so as to interfere as little as possible with the public use and enjoyment of the park, he would have ruined his professional reputation. The authors of this plan have no professional reputation to lose, but they have made it impossible for any worthy result to come out of the buildings for which they have invited plans, after themselves imposing a plan which no competent architect will try to treat because he thinks he can design something worthy of the purpose, and will only treat at all in case he imagines himself to possess a ‘pull.’ It is true that the Commissioners permit the modification of the plan in detail ‘within reasonable limits.’ But no tinkering of detail will convert their plan into anything suitable. They have made the ruinous mistake of supposing that architectural advice was not needed in order to solve the problem, and that an architect could do something with a building already spoiled by the crudities of amateur planning. Their plan is the product of that rashness which goes with entire inexperience and assumes that the first thing that comes into a man's head is a final and complete solution of his problem.”

DISINFECTION AT THE NEW YORK QUARANTINE.

DR. G. M. STERNBERG, in his address as President of the American Public Health Association, delivered at Memphis, November 8, 1887, gives the following account of the ceremony performed at the New York Quarantine as observed by him when entering that port last August on a vessel from Brazil:

“As another illustration of the evils arising from the present system of supporting quarantine establishments, I will mention a circumstance which occurred upon our arrival at the port of New York. With the deputy health officer, who boarded our ship, came a man with a jug. I was informed by one of the officers of the ship that he was to disinfect the vessel. Being somewhat curious to know the method of disinfection employed, I asked the ship's surgeon to go with me to inspect, when, after a detention of less than one hour, we had started from the quarantine station for our wharf. We found that the man with the jug had lowered a bucket by means of a rope through one of the hatches between decks. Upon pulling up this bucket I found that it contained two or three pounds of some powder which had been wet, probably with acid solution, and which gave off an odor of chlorine. No doubt when first lowered between decks there had been a considerable evolution of chlorine, but in the vast space to be disinfected, it was so diluted that at the end of an hour I did not detect the odor of chlorine gas when I lifted the hatch, and it was only by approaching my nose to the bucket that I was able to ascertain what disinfectant had been used. The most curious part of the story is that I was informed that the bucket had been lowered between decks to disinfect a quantity of hides which were stored in the hold. What was the object of this ‘disinfection’? Evidently not to disinfect, for no one at the present day would think of maintaining that the hides in the hold had been disinfected by the procedure of the man with the jug.

“The only object that I can conceive of depends upon the fact that there is a fee for disinfecting, which must be paid by the agents of the ship; at least I was so informed by one of the officers of the ship.”

OUR ARCHITECTURAL ILLUSTRATIONS.

RESIDENCE OF MRS. COWDEN, FAR ROCKAWAY, L. I.—
M'KIM, MEAD & WHITE, ARCHITECTS.

PRESBYTERIAN CHURCH, OCEANIC, N. J.—CARRIERE &
HASTINGS, ARCHITECTS.

THE subject of our illustration is the Presbyterian Church at Oceanic, New Jersey. It cost \$5,500, including pews, stained-glass windows, and wrought-iron fixtures, chancel and pulpit. The exterior is entirely of cedar shingles, brick foundation. Outside shingles left natural, inside oiled. Accommodation for 275 people. Carriere & Hastings, of New York, were the architects.

THE GETTYSBURG CYCLORAMA BUILDING.

THE iron building for the exhibition of the Cyclorama of Gettysburg, G. W. & W. D. Hewitt, of Philadelphia, architects, was designed and built by the New Jersey Steel and Iron Company, Trenton, N. J., for Mr. C. L. Willoughby. It was first erected in Brooklyn in the summer of 1886, and is now just re-erected in this city, whence it will in turn be removed to other localities.

The requirements for this building, to meet the unusual conditions of its nomadic career, have been successfully filled by the design, which secures strength, rigidity, and symmetry, with the essentials of simplicity, lightness, plain details and convenience, rapidity and economy of erection without special workmen. The trusses are, admittedly, very light, having little but their own weight to carry, and the wind strains diminished by the curvature of the surfaces and distributed throughout the whole structure by the unusually complete lateral systems, while the columns, well-braced, and anchored to the piers, form with the continuous corrugated iron sheathing a very strong wall.

All the members of all the trusses and the other separate pieces are duplicates, the field connections simple, well-arranged, and fastened entirely with bolts, those of the trusses and columns being made with taper bolts turned to fit a corresponding hole accurately reamed by a special tool after assembling of pieces. These bolts have given excellent satisfaction, secure complete bearing, and draw the pieces together as tightly as rivets.

The canvas is supported by a ring 120 feet in diameter, made of 8-inch channel-bars attached beneath the roof trusses at the end of the lower chord and bracketed directly to the columns.

This ring was required to be very accurately constructed, so as to cause the ends of the canvas to exactly meet and preserve the continuity of the painting. This was perfectly accomplished by bending the channel sections to a template and facing the ends in a rotary planer to the required angle of $22^{\circ} 30'$. Wind strains were figured for a maximum pressure of 25 pounds per square foot on an area slightly smaller (to allow for the diminished resistance offered by a curved surface) than that of a vertical section of the entire building.

The total iron weight of the structure, exclusive of corrugated sheathing, is 200,000 pounds, and the contract price, inclusive of erection and exclusive of foundation piers and roof covering of boards, tin, and glass, was about \$10,500.

SOME DETAILS OF WATER-WORKS CONSTRUCTION.

No. IV.

BY WILLIAM R. BILLINGS, C. E.,
Superintendent of Water-Works, Taunton, Mass.

(Continued from page 583.)

PIPE-LAYING.

Cement-Lined Pipe.—Wrought-iron pipe after being lined with cement is not ready for immediate use. It should be allowed to dry for one or two weeks, the time varying with the weather, and the readiness with which the mortar sets, and a careful man will not subject the finished pipe in the trench to pressure for five weeks after laying, unless the pressure be very light. No derrick is needed in laying this pipe, for if circumstances do not allow the men on the bank to hand the lengths to their comrades in the trench as easily as they could lift a piece of stove-pipe, two pieces of rope will furnish means for easy lowering.

The cement bed and covering is "mud," in the language of a cement-pipe-laying gang, and is mixed sand and cement, three to two, in a mixing-box on the bank.

It may be conveyed to the trench in any convenient manner; in V-shaped troughs, ten feet long, with handles at each end, or in pails, or in wheelbarrows. Before placing a length of pipe, a bed of a dozen pailfuls of cement is spread along the bottom of the trench, thicker than the covering desired, and the pipe, with the rivets down, is pressed firmly into it; "mud" is then brought in sufficient quantities to allow the pipe to be plastered an inch in thickness, leaving the joints uncovered. The cement is spread with rubber mittens, and the men in the trench who handle the "mud" wear rubber leggings.

The joints are covered with pure cement, and are often made by the foreman of the pipe-layers, who can easily keep ahead of his men, for to a practised hand the operation is simple and rapid.

The exposed pipe-ends are first covered with cement even with the finished pipe, and a sheet-iron sleeve is then slipped along so that its centre is directly over the joint. A pin of $\frac{1}{4}$ -inch wire stuck into the trench will locate the butt joint of the two pipes, and make the placing of the sleeve an easy and certain matter, and the sleeve is then in turn covered with the pure cement.

This pure cement will crack, perhaps, and must be patched, and for this the regular "mud" will answer.

To protect the covering from too sudden drying, the pipe should be lightly covered as soon as it is laid, but the final covering should be delayed forty-eight hours.

The specials for cement-lined pipe can be made by any good sheet-iron worker.

Tee and Y branches are to be soldered at their junction and strengthened by knees of $\frac{1}{4}$ -inch flat iron, one inch wide, riveted to the metal.

Plugs are simple cylinders filled solid with "mud," but they are to be braced in the trench with a heavy stone.

JOINT-MAKING.

There is not, to my knowledge, any standard form for a cast-iron pipe-bell or socket. This is unfortunate. The lack of agreement in this particular is, it is true, not nearly so unfortunate as the still greater lack of uniformity which prevails in the thicknesses which are specified for cast-iron pipe, but a standard is desirable.

The general form of a bell and spigot pipe-joint is shown in Fig. 15.

In practice, the two lines which in the sketch run through the word "and" should form one, and they will when the spigot end is pushed "home." A space is left in the sketch to make the parts more distinct. A water-tight joint capable of standing great pressure is secured by using a soft compressible substance in combination with molten lead. For the first substance one may use jute, hemp, old rope, old rigging, oakum, or almost anything of this nature, as the principal office of the "yarn," as it is oftenest called, is to prevent the molten lead from running into the pipe. It has been suggested that the yarn in the joints of a distributing system may, by its compressibility, serve to mitigate the shocks which come from water-hammer, and again that the yarn will in time decay and may then furnish feeding-ground for noxious animal or vegetable life which may appear at one time or another in any water-supply.

At present these suggestions belong to that class of problems which are of especial interest to the investigator. Of the first we may say that it has a reasonable appearance, and of the second, that if it be true the elastic cushion is lost when decay is complete.

The writer's experience has led him to adopt for yarn the article known to the cordage trade as 12-thread Russia gasket, tarred.

A larger size may be needed for 24-inch and 48-inch pipe, but the 12-thread has worked well on all sizes up to and including 16-inch.

For lead, use any soft pig, such as the "Omaha" or the "Aurora" brands.

In a gang of fifty, one man can find enough to do in yarning and pouring the joints. Let the yarn be cut into pieces long enough to go around the pipe and lap a little.

The yarner takes a bundle of these "ends" as large as he can conveniently carry from one bell-hole to the next,

FIG. 15.

a couple of cold-chisels, a yarning-iron, and a hammer, and, going to the first joint that is ready, he should to begin with see that the joint room is even, or alike all around the pipe, and if it is not the chisels should be driven into the small places so as to crowd the pipes into line. This, of course, provided the pipes are intended to be in line, and one is not trying to get around a curve by "taking it out of the joints." The relative amounts of lead and yarn

to be used per joint do not seem to be determined by any hard-and-fast rule. Referring to Fig. 15 we can see that there is little except stiffness gained in putting in more than enough lead to reach back of the semi-circular groove, say one-quarter or one-half an inch, so that the depth and form of the bell must determine to a great degree the exact depth of lead in the joint.

Yarn is cheaper than lead, but the time consumed in yarning may, with lead at a very low figure, make it cheaper to put in only a shred of yarn and save time by filling up the joint with lead.

I think some contractors have figured in this way, for joints of their making which I have had occasion to dig up seem to have been made upon that principle.

Tarred stuff of some sort packs better and is easier to handle than dry rope or strings. The tarred Russia gasket, bought in 100-pound coils, is convenient to use for slings and lashings, and is just as good as ever for yarning after any other use. To guide the molten lead into the joint, we must have either a "roll" made of ground fire-clay upon a rope-yarn core, or a jointer. If a jointer is used, the yarner carries it with him in the trench, but a clay roll must be kept in shape and ready for use by the lead-boy. The patent jointers are made of canvas, rubber, and sheet-steel. They are very convenient, and can be obtained of dealers in water-works supplies. They are especially useful in wet places, for they do not easily blow out if a little steam is formed, and the clay-roll will frequently give trouble in this particular. For making a good clay-roll we require finely-ground fire-clay, a piece of board somewhat longer than the finished roll, a strand of rope, and a pail of water. Mix two double handfuls

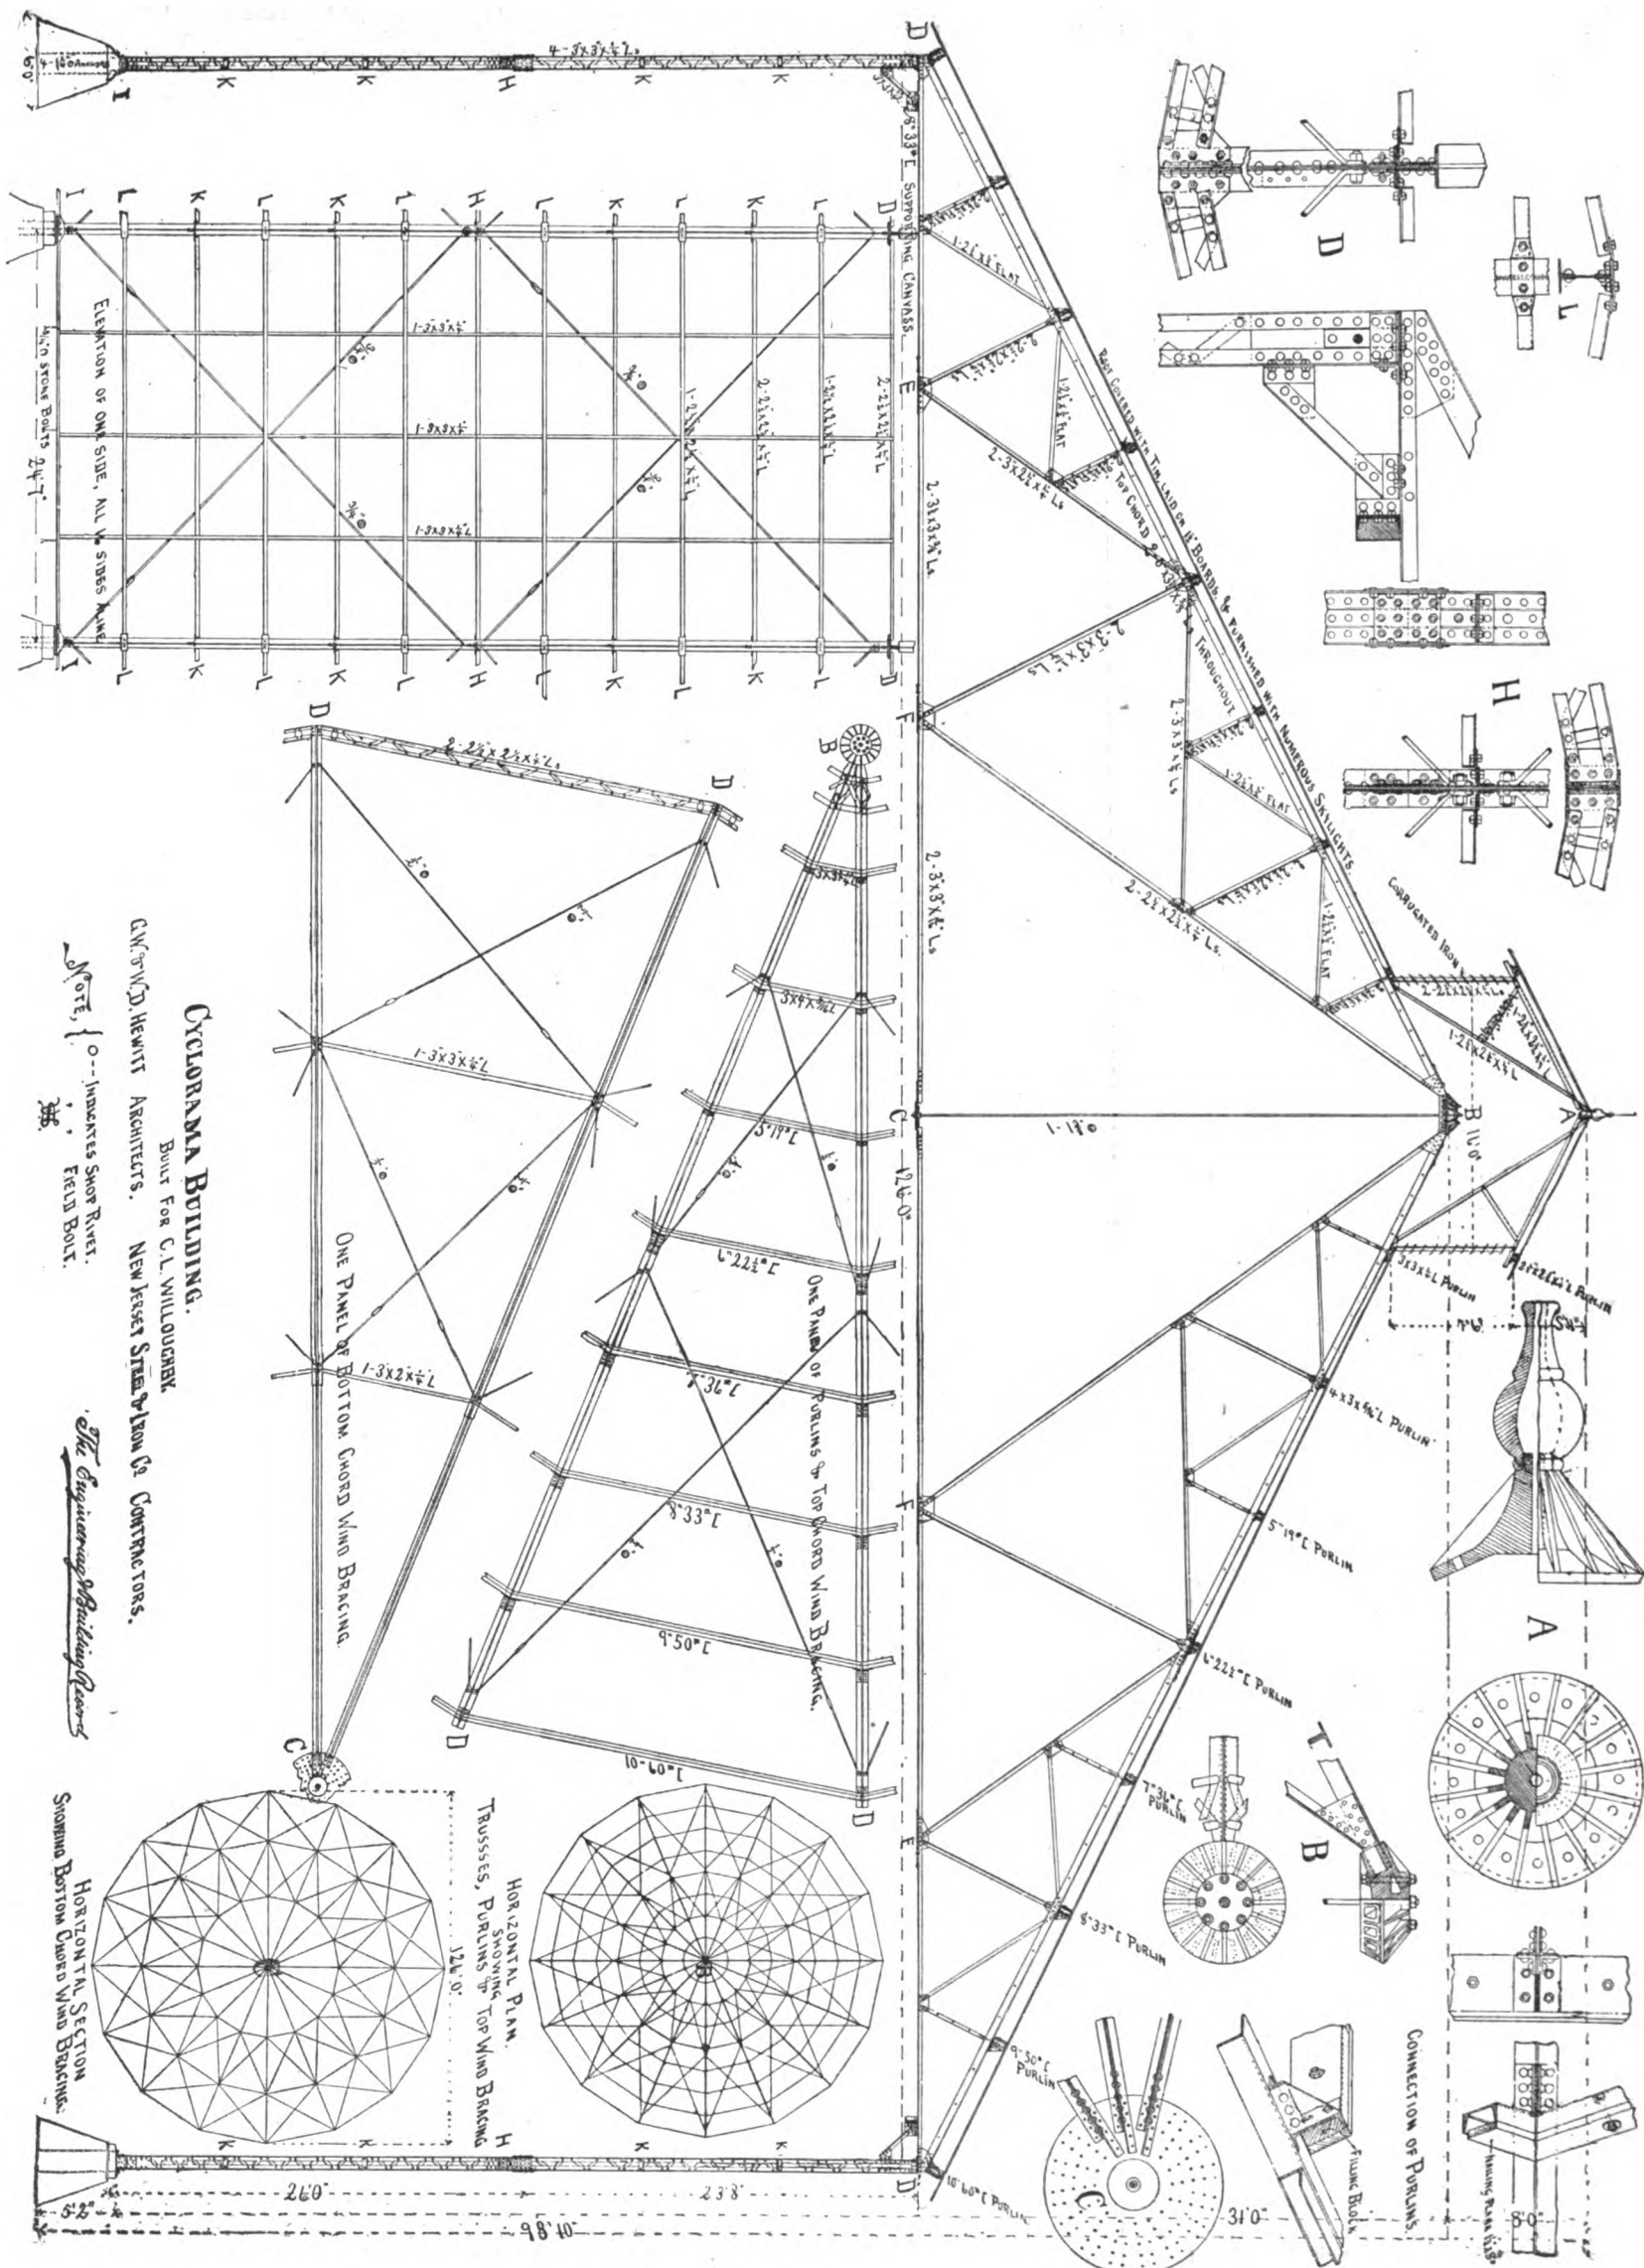

FIG. 16.

of the clay into dough, and after enough kneading to get out the lumps, roll the mass into a short thick club. With a stick or a chisel cut a slit lengthwise of the club and half-way through it, and lay therein a strand of rope a foot longer than the outside circumference of the pipe. Bring the two edges of the slit together, and then, by working, stroking, squeezing, wetting, and rolling, the roll may be drawn out to an inch in diameter, and eight or ten inches longer than the outside circumference of the pipe. This roll-making is the work of the lead-boy, who should keep the roll, when not in use, lying on the board covered with a wet cloth, and mend and wet it as the wear and tear demand. When he has packed the proper amount of yarn into the joint, the yarner should call out "roll" to the lead-boy, who will bring him the roll by the two rope-ends.

The roll is wrapped about the pipe close to the bell, bringing the two ends on top, and turning them out along the pipe, so as to form a convenient pouring-hole. The roll should be pressed firmly into place against the bell, and the molten lead poured in not too rapidly. The lead should be hot enough to run freely, and the furnace should be frequently moved, so that the hot lead need not be carried far enough to give it time to cool. After the joint appears to be full, and the roll has been removed, the yarner should examine the joint carefully all around, and especially on the bottom, to make sure that the joint is well-filled; and if a cavity is found it should be filled by a second pouring if possible, or by a plug of cold lead. The calker follows, and should begin on the joint by using his chisel, cutting off the lump at the pouring-hole, and then driving the tool lightly between the lead and the surface of the pipe all around. Having, by this operation, lifted the lead away from the pipe, he begins with the smallest tool and drives back the lead, a little at a time, all round, and, following with the larger tools, sets the metal in firmly with strong, even blows.

Calking is hard work and needs a muscular man to follow it steadily, but it is not enough that he be—

"Darbyshire born and Darbyshire bred,
Strong in the arm and thick in the 'ed,"—

ONE PANEL OF PURLINS & TOP CHORD WIND BRACING.

for he should know when a joint is right, but above all he must be trustworthy and faithful, and certain to call attention to any joint that he cannot get into proper shape without help. The quantity of power required to pull apart a well-made bell and spigot joint will surprise one who sees it measured for the first time.

In the experience which the writer has had in endeavoring to pull apart such joints the amount of force applied has not been measured with exactness, but a heavy clamp-jack having a pair of $1\frac{3}{4}$ -inch screws with four threads to the inch, worked with a lever about thirty-six inches long, was insufficient to pull apart any but pipe from which the rim or bead on the spigot end had been cut off, so as to leave a smooth end.

Some notion of the force applied to the joints by this clamp-jack, Fig. 16, may be had by using the formula for power exerted by screw given in *Goodeve's Mechanics*:

$$P = \frac{w r}{a} \tan (\alpha + \theta),$$

in which

P = power applied at end of lever.

r = mean radius of screw-thread.

a = length of lever.

α = angle of thread.

θ = angle of repose.

$\tan \theta$ = coefficient of friction.

w = force exerted by screw.

Then,

$$w = \frac{P a}{r \tan (\alpha + \theta)}$$

FIG. 17.

In Fig. 17, let B A represent the developed circumference of the cylinder on which thread is traced, and P A the pitch of the thread, and P B A = α = angle of thread. Then

$\tan \alpha = \frac{P A}{B A}$ and substituting the values for this case,

calling $1\frac{1}{2}$ -inches the mean diameter of screw-thread,

$r = \frac{1}{4}$ inch. $P A = \frac{1}{16}$ inch.

$\tan \alpha = \frac{.225}{4.711} = .053$ and $\alpha = 3^\circ 2'$.

$\tan \theta = .08$ and $\theta = 4^\circ 35'$.

$\theta + \alpha = 7^\circ 37'$. $\tan (\alpha + \theta) = .133724$.

$P = 100$ pounds. $a = 36$ inches.

$$w = \frac{P a}{r \tan (\alpha + \theta)} = \frac{3,600}{.75 \times .134} = 36,000 \text{ pounds.}$$

This formula makes no account of the power expended in overcoming friction at the pivot end of the square-threaded screw, and the result above given should be reduced 15 or 20 per cent.

The same clamp-jack has been found useful in pushing a hydrant off its branch for repairs.

As to the quantity of lead used in joint-making on cast-iron pipe the following notes are offered. Four streets having a total length of 3,112 feet of 6-inch pipe consumed 1,997 lbs. of lead or $\frac{1}{4}$ lb. per running foot. Two streets, 1,796 feet of 8-inch required 1,514 lbs. of lead or $\frac{1}{4}$ lb. per running foot.

During the past season the writer has directed the laying of 10,000 feet of 16-inch, 1,915 feet of 8-inch, 1,479 feet of 6-inch, 1,817 feet of 4-inch pipe. For purposes of this calculation it is fair to say that the quantity of lead varies directly as the diameter of the pipe, and that the above is equivalent to 11,927 feet of 16-inch pipe, and to make the joints on this 23,579 lbs. of lead were used, or 1.97 lbs. per running foot. This is larger, as of course it would be, than the amount given by a single experiment on a short piece, for ten pigs weighing 96.7 each (average weight) filled the joints on 550 feet of 16-inch, or 1.75 lbs. per running foot.

The quantity of yarn used is not large, comparatively speaking, and on the three small sizes, 4, 6, and 8-inch, with the price at ten cents per pound, $\frac{1}{10}$ of a cent per foot is a safe figure for estimating purposes.

The quantity of pipe laid and the number of joints made in a day will, of course, vary greatly in different cases. If a man is trying to see how many pipes he can get into a trench, with the minimum amount of thought as to how they are put in and jointed, he can make a wonderful record, and the man who comes after him, and has to take care of the pipe-line under the shocks of service, will appreciate more keenly than any one else the value of such a record.

The following notes of actual work are offered, not in any sense as instances of model performance, but as simple illustrations: Time, July 6, 1887; gang 60 men, 16-inch pipe, 2 yarners, 2 calkers, 4 to 10 men digging bell-holes, 30 bell-holes per day, 400 feet of pipe laid and jointed in ten hours.

(TO BE CONTINUED.)

PAVEMENTS AND STREET RAILROADS.

No. XIX.

(Continued from page 680.)

WOOD PAVEMENT IN THE METROPOLIS.*

CORRESPONDENCE.

MR. G. P. CULVERWELL approved of the contour of the carriageway in Fig. 2, but thought that, if anything, the slopes might be reduced. It was ordinarily admitted that wood was a most slippery roadway, and thus every precaution should be taken. The sharp camber of the old macadam or stone pavement was too often followed, but it was unsuitable, and placed vehicles at a disadvantage, especially when starting from the curb. The cross-section should be represented by two gradients, say of 1 in 40, from the channels to the crown, the latter being slightly eased off. In level roads the cross-section necessarily varied somewhat in order to drain to the gullies.

Figures 5 and 6 were typical sections, and had been carefully taken recently. The east and south ends respectively were at gullies, whilst the west and north ends were midway between gullies, both streets being level. It was to be noted that steep gradients transversely were specially objectionable, as in this direction the blocks were made to abut close one to the other without any joint, and this gave little foothold. He did not comprehend the remarks as to pitch-pine producing a "jarring, bumping motion." He had examined the portion of that pavement in King's Road, and traveled over it in various vehicles without noticing any increase of bumping motion, but there was somewhat greater resonance than where the wood was softer. He would expect to find the coefficient of elasticity of pitch-pine greater than of yellow wood. It was misleading to say that creosoting "tends to produce premature internal decay," although, indeed, perhaps the large amount of inferior work done in the market might form a sufficient excuse. Creosoting consisted in driving out the sap, and then substituting oil. If the first portion of the operation was not effected, the oil formed merely an external coating, preventing the sap from escaping, and "dry rot" set

up. He, however, thought that creosoting was unnecessary and even in some respects undesirable for wood paving. Creosote was chiefly of use in the case of porous woods exposed on all sides to the weather, in prolonging the ordinary life of the sapwood and wood next the sap. It did not render the sapwood harder, or better able to withstand abrasion under traffic; and it was almost useless to creosote the heart-wood of pitch-pine, the wood being already so full of resin that little oil was taken in. He had no hesitation in saying that the money expended in creosoting would be better laid out in the careful selection of heart-wood timber of uniform quality; and he thought there were data to show that the life of pitch-pine pavement might, without undue maintenance, easily reach ten to twelve years as a first-class roadway under the traffic standard of 750 tons per yard width per day. The depth of block should be regulated to some extent by the weight of traffic, the aim being that the block should be fairly worn out by abrasion just before decay from weather or other causes set in. With pitch-pine, even 5 inches appeared unnecessarily deep, considering that the maximum annual wear in King's Road was given as under 0.1 inch, and in Oxford Street blocks (presumably deal), worn as thin as $1\frac{1}{2}$ inch, had not failed under the traffic.

"Top-dressing" was important, but the material used was often unsuitable and too much was put on, with a result that, upon the first rain, the roadway was almost impassable for pedestrians, as in the case of the Strand at Charing Cross when last repaved. The material should be fine-screened sharp gravel, deposited in successive thin layers. Stones of the size of walnuts only rolled about, the wood not presenting a sufficiently hard anvil to crush them, and the material did not work its way into the wood so well when in a thick layer.

The opening up of streets for repairs to gas and water mains, etc., was most objectionable, and peculiarly so in the case of wood pavement, owing to the time necessary for the proper restoration of the latter. It was to be regretted that a comprehensive scheme had not been carried out whereby to provide subway accommodation in the metropolis for gas and water pipes, telegraph and telephone wires, etc. Many of the streets were much too narrow, whilst the evil daily increased, and thus every means should be taken to supplement their deficiencies.

More information was desirable so as to be able to determine the description of wood, size of block, and width

of joint best adapted to varying conditions of traffic and gradient. He thought 1 in 20 too steep for any of the forms of wood-paving at present employed; and whenever the gradient exceeded 1 in 40, extra provision should be made for cleansing and sanding, especially in time of frost.

Sloane Street at present afforded a good opportunity for examination, as the paving and concrete foundation were being taken up throughout its whole length for a width of about 16 feet, in connection with new sewerage works. Such examination showed that the concrete foundation was clean and sound, and there was no appearance of moisture or objectionable matter having infiltrated. The blocks were not perceptibly rounded on top, and were in good condition, showing little soakage, and the cement grout bonded to them remarkably well. The cement joints were of uniform width, and were very little below the level of the blocks. The blocks were burred about $\frac{1}{4}$ inch upon the sides next the cement, and not at all at the ends where block bore against block. This pointed to the conclusion that blocks of uniform thickness, laid touching each other upon all four sides, and without any cement or other joint, would form a most durable pavement, whilst upon level roads it might give a sufficient foothold. The compression set up would effectually keep the blocks in place, and prevent infiltration of moisture. Expansion in the transverse direction of the street appeared to have been sufficiently allowed for, as the blocks bedded fairly upon the concrete, and no buckling away from it or disturbance of the foot-pavements, had been noticed. That the compression in the longitudinal direction of street was great was evidenced by the line of blocks continually cambering toward the free end. This camber averaged about one inch in the excavation width of sixteen feet. This showed the advisability of laying wood pavements in long even gradients; and where the vertical curves at the summit levels were sharp, expansion should be provided for, otherwise buckling, followed by disintegration, might take place. Compression was most desirable for wood, and directly added to the life of the blocks, whilst further preventing objectionable soakage. Hence it appeared why a rigid joint, such as cement, was preferable to a mastic one. In the latter case, in place of the wood being compressed, the substance of the joint itself was expelled, and part, no doubt (especially if the transverse expansion had not been allowed for), found its way underneath the blocks, and uneven bedding, followed by disintegration, resulted. In connection with this matter of compression appeared a direct objection to the use of creosoted blocks, as these did not expand, and compression was not set up, and also the cement grout did not bond to them as well as to plain ones. This explained the several instances noted by the author of the ease with which creosoted blocks were taken up, and of the moisture having been found between them.

He was informed of one case—that of the long-girder bridge over the River Foyle, at Londonderry—in which the cement grout had never set. This the engineer in charge attributed, no doubt correctly, to the unremitting vibration night and day, as every care had been taken with the materials. Henson's patent felt bed and joint appeared peculiarly applicable to such cases.

In conclusion he congratulated the author upon having at an early stage adopted an excellent and economical system of pavement, singularly free from faults or objections, and one that bid fair, with minor modifications only, to be largely employed in the future.

Mr. W. H. Delano regretted that the author should have perpetuated confusion by using the words "asphalt," "asphaltic," when the substances he referred to were evidently gas-tar and gas-tar-mastic—namely, gas-tar mixed with chalk and gravel. Asphalt was a natural bituminous limestone; asphalt-mastic was the same, mixed with natural bitumen, and when mixed with grit was called gritted asphaltic mastic.* He understood that pine sets cut from Swedish yellow deals six inches deep, three inches wide, and eight to eleven inches long, laid on a Portland cement foundation six inches thick, cost 10s. 6d. per square yard, exclusive of demolition of old roads, carting away old materials, and regulating the subsoil to a proper contour. This price was low and probably misleading as a guide to contractors' prices for similar work, for it seemed to include no general expenses. A contractor paid rates and taxes, interest on money disbursed, cost of plant and tools, rent employees, which made his general expenses from fifteen to twenty per cent. Local boards, who were their own contractors, had none of these to count, but it was probable that their general expenses really exceeded those of a contractor, just as the management of railways by the State cost more than that of private companies. The standard traffic of 750 tons per yard width per diem seemed a misleading formula, for the wear and tear of a road did not depend so much upon the weight passing over it as upon the speed at which that weight traveled. There was also the important element of width of tire, the state of the atmosphere, the camber of the road, and the mode of traffic, cross, heavy, one side empty the other loaded, etc., etc. Take the new three-horse Paris omnibuses carrying, when full, forty-six people including driver and conductor, weighing when full $5\frac{1}{2}$ tons, the width of the wheel tires being only $3\frac{1}{2}$ inches, running at a speed of seven to nine miles an hour, and compare the same weight on a $4\frac{1}{2}$ -feet wide smooth cast-iron roller dragged at $1\frac{1}{2}$ miles an hour. The latter improved a road, the former rapidly destroyed it.

DOMESTIC ENGINEERING, ETC., IN THE
EQUITABLE LIFE INSURANCE BUILD-
ING, NEW YORK CITY.

No. VII.*

(Continued from page 680.)

STEAM-HEATING.

In the steam-heating, no special system is strictly followed. In such a large job unusual problems arose and were met by the engineer, Mr. Wilson, as the occasion required.

The heating-main, commencing at 11 on the cellar plan and going to north wall, is 10 inches diameter and measures 56 feet to the wall; it is provided with the usual expansion-bend at 38; from this corner to the next bend, which is at the corner of Broadway and Cedar Street, it measures 220 feet; from there to valve No. 45, 75 feet, the diameter being 7 inches at the valve, the reduction being made one inch at a time. A riser is taken off the main at every pier along the route, their diameters being usually 3 inches, unless for special duty. At the corner of Broadway and Cedar Street a large copper bend, 96, of 10 feet radius, is introduced, which effectually absorbs the expansion of the two lengths. Beyond valve 45 and around the south wall back to the steam-main at 12 the pipe increases in diameter from 7 inches to 10 inches, as with the main already described. At the corner of Broadway and Pine Street a similar large copper elbow or bend, 97, is put in for expansion reasons, and found to operate much better than any expansion-joint could do.

As previously stated, the globe-valves 41 and 42 shut off the high-pressure steam from the heating-mains; when they are opened the entering steam is reduced in pressure through the reducing-valves T T. No steam risers are taken off direct, but invariably at a distance from 3 to 6 feet, to right or left of the point on the pier where it is to ascend, thus giving an easy and unobjectionable method of absorbing the expansion and one that needs no looking after. The risers are hung at a point about half-way of their length, usually on the third floor; the method of hanging is shown in Fig. 11. A piece of boiler-plate A is built in the wall or pocket containing the steam and return risers, with holes in it in sufficient number and the diameter equal to the outside diameter of the pipe. This allows for the expansion going both ways from the point of suspension, decreasing the risk of sprung joints from what would be the case if the pipe rested on beams in the cellar and the whole expansion went from the bottom up.

In the 50 miles of steam-piping in use there is not one expansion-joint of any kind, and there has been no case of leakage or trouble from not using them.

Particular attention was given to having a means of expansion in all directions in the pipes themselves by a judicious use of elbows; this is successfully accomplished, as no pipe, however obscure or small, is not provided with ample means in this direction. Perhaps the severest test of this principle adopted was at the corner of Broadway and Cedar and Broadway and Pine. Here large copper bends were used of 10 feet radius to turn the corners; the run of pipe along the north and south walls to those bends is 220 feet and along the Broadway front 150 feet, but no trouble was experienced when steam was turned on. The steam-risers going to the tower are 4 inches diameter, and are 3½ inches in several special cases. In nearly all cases one radiator on each floor is fed from one riser; in a few cases two and three are taken off. The radiators used are vertical tube return-bend pattern and number between 700 and 800.

The mains are hung from the I-beams of the ceiling by straps that encircle the pipe, their ends passing up over the lower flange of the beams and bolted together to keep from spreading. Flanges have not been used in any one case unless where absolutely necessary for a final connec-

tion. This applies to the largest pipe as well as the smallest, the reason given being that flanges absorb a great deal of expensive packing which wears out, and they cannot be relied upon for permanency like the screwed joints.

Gate-valves are used exclusively in the exhaust-pipes leading to the heating-mains.

The water of condensation is returned through two separate mains, which begin on each side of the main Broadway entrance under the sidewalk. They make the circuit of the building and are of increasing diameter, beginning with 2½ inches and ending in 4-inch, as shown at the feed-pumps, Fig. 12, which is a side view of the arrangement of the pump-governors, pumps and local connections for forcing the return and fresh water into the

pipe P, and force it into the boilers through pipes B and C. The reduction of pressure made in the return by this action has the effect of increasing the flow of condensed water in the direction of the boiler from the remotest corner of the system. When part of the exhaust steam is unavoidably going to waste in spring and fall, and the return mains are not supplying enough to maintain the water-level, the valves N N, which are connected to the city water, are opened slightly so as to supply the deficiency, the water in that case passing through the feed-water heater before entering the boiler, which it reaches at a temperature of nearly 212°.

During the summer season, when the pump-governors are not in use, the whole supply of water to the pumps F and G is taken in through pipes J and valves N N, and the

RETURN WATER PUMPS AND PUMP GOVERNORS

FIGURE 12.

boilers, and also keeping the level of the water in the return-mains some 4 or 5 feet below the water-line in the boilers.

In Fig. 12 H and I are the pump-governors; F and G the boiler feed-pumps; A the return-main, 4 inches diameter; J the 4-inch suction-pipe connecting with city water at storage-tanks 62 and 63; K K K is the steam-pipe connecting with the pump-governors, while T T are the direct steam-pipes which are used when the pump-governors are not in use; pipe E is an equalizing pipe, marked 92 and 93 on cellar plan, and connecting with the heating-mains on the low-pressure side of the reducing-valves T T on cellar plan. The devices are in duplicate so that the work

ELEVATION

PLAN

FIG. 11.

may not be retarded if one gives out or is stopped for repairs.

The water of condensation, as it seeks the lowest point in the mains, flows into the governing apparatus through pipe A and valves S S to the chambers H I. Here is placed a float which is connected to the levers U U, which in turn operate a regulating-valve V, which admits just so much steam to the pumps as the height of the float will allow. The office of the float being to open the valve V as it rises, and closing the valve as it falls, hence as the water of condensation increases and the float rises the valve V opens and admits more steam to the pumps through pipe K, enabling them to run faster and draw the accumulation of water out of the mains through

whole supply of steam through steam-pipes T T instead of pipes K K. The valves R R on the chambers H and I are for blowing-off purposes only. The pipes B C E are all three inches in diameter. Pipes E, corresponding with those marked 92 and 93 in cellar plan and connected to the heating-mains on the low-pressure side of the reducing-valves, T T, are for the purpose of insuring the pressure in the chambers H I being the same as that in the heating-mains, and maintaining a steady action in the working of the apparatus.

The pipe C corresponds with pipe X in cellar plan, while B corresponds with that marked Y in same. By opening valve on pipe C, and closing that on pipe B, the feed-water is forced to heater R in cellar plan and back through pipe Y, and thence to boilers through branches 46 and 47, etc., to feed-valves in front of boilers in a heated state. While by closing valve on pipe C, Fig. 12, and also valves 48 and 49 on cellar plan and opening valve B, Fig. 12, which corresponds with valve 50 on cellar plan, the water no longer goes around by way of heater R, but directly to boilers through branches 46 and 47 as before.

The main offices of the Equitable Life Assurance Society and also the main corridor of the building are heated by indirect radiation. The former by means of the indirect radiators shown in cellar plan at 98; the latter by radiators placed near the cellar ceiling immediately below the corridor. The grated openings for admitting the heat to the corridor are placed by preference in the side walls rather than in the floor, on account of the odor that arises from accumulations of earth on the grating.

The other article, on some plumbing details not yet finished, will appear in a later issue.

The architect of the building was Mr. George B. Post, of New York; the builder, Mr. David H. King, Jr.; the engineer, Mr. James F. Wilson; the master plumber, Mr. William H. Quick.

EXPERIMENTS have recently been made on the Seine, with M. Pagan's new cable anchor, for the stoppage of steamers in motion. The apparatus is a cable having on it a series of canvas cones, which open out by the action of the water, and close again when drawn in the opposite direction. The "Corsaire," going thirteen knots, was stopped in seven seconds in a space of 26 to 30 feet. For comparison, the steamer when stopped in the usual way, by reversing engines, took thirty-four seconds, and a space of 350 to 360 feet.—*Iron*, October 14.

AN interesting International Exposition will be opened in Paris on December 25. It will be devoted to all apparatus, etc., to prevent fires in theaters, for the lighting of theatres, for the extinction of fires, and for aid in case of fire.

*No. I. of these articles, containing the first installment of Sketches of Plumbing, appeared in our issue of October 8; No. II., General Description of Building and Plant, October 15; No. III., Details of Pumps and Boilers, October 22; No. IV., Smoke-Stack and Passenger-Elevator Water-Supply, October 29; No. V., The Elevators, November 5; No. VI., Pneumatic System, November 12.

SOME SKETCHES OF PLUMBING IN THE RESIDENCE OF WILLIAM F. WELD, ESQ., BROOKLINE, MASS.

No. I.

THE plumbing and drainage-work in this notable building possess numerous interesting and novel features, which we hope to make the subject of several articles.

The accompanying details and sketches show the several arrangements of the principal parts of the plumbing, etc., in the new villa residence of William F. Weld, Esq., in Brookline, Mass. The drainage was planned by E. W. Bowditch, C. E., and the plumbing-work was done by Henry Hussey & Co., the architect being Mr. E. M. Wheelright, all of Boston.

Figure 1 shows the manner of arranging the house-trap, foot-vent, etc., outside the front wall of the house. It also shows the tunnel in transverse and longitudinal sections through which the cast-iron sewer-pipe is run through the grounds to the city sewer. The same tunnel is also utilized for the water and gas pipe service. It is 30x30 inches in

placed in the pipes as to come just through the copper. Then a leaden sleeve is placed about the hub, with its upper edge turned down within it. Into this a full length of pipe is placed and a joint of lead run similar to any of the other joints of the pipe. The lower edge of the sleeve is wiped to the copper roof. The object of this of course is to make a thoroughly water-tight connection with the copper roof that will be at the same time sufficiently elastic to compensate for any slight difference of length caused by expansion or contraction or by settling.

Figure 3 shows the special grease-trap used. It is a cement cylinder, with hemispherical end set in the ground. It is 5 inches thick, 36 inches in the clear in diameter, and somewhat over 5 feet deep. The kitchen and pantry pipes enter it 2 feet 6 inches from the top and the roof water enters much higher up. About 6 inches lower than the sink and pantry pipes the level of the water and grease with the apparatus is maintained. The outflow-pipe, of course, is at this level, but, as will be noticed, the water leaves the basin at a much lower level, the end of the

The following officers were elected: Mr. John Date (Chairman); Ald. V. Grenier, Vice; Mr. J. W. Hughes, Secretary-Treasurer; Messrs. J. B. Drapeau, G. Yon, H. Garth, J. Mattinson, with the regular officers to be a Committee of Management.

Mr. Savignac acted as joint secretary and interpreter, it being the intention to conduct the affairs of the section in the French and English languages.

It was unanimously resolved that active steps be at once taken to form a plumbing class in connection with the Government trade-schools. Messrs. W. Brittan, W. M. Briggs, and F. Horton were appointed a special committee to select a teacher and make the necessary arrangements.

Novelties.

Under this heading we propose to describe and illustrate appliances of probable interest to our several classes of readers. The selection will be made without reference to the wishes of agents or patentees, being governed solely by considerations of novelty, ingenuity, and probable interest to readers, and especially the fact that they have not been elsewhere described. As a rule we shall make no comments, and it is to be distinctly understood that a notice does not imply approval. No charge will be made for these notices, and any offer of pay for their insertion will insure their omission. We shall be glad to have our attention called to novelties suitable for this section.

STEAM-RADIATOR.

THE accompanying cuts show a novel positive steam-radiator, lately patented by Ezra F. Landis, of Lancaster, Pa.

The object of the apparatus is to produce a radiator in which the sections will be easily retained steam-tight whatever may be their relative arrangement, the invention relating mainly to the construction of the joints between said sections.

The radiator as here shown and used is composed of any number of elements B B, which, taken as whole, make a coil set on end.

The steam is admitted, as usual, through the pipe *a* into the bottom of the end section A, and after ascending therein passes through the aperture into the top of one of the branches of the section B. The top of each section having a diagonal partition *b*, as shown in Fig. 2, the steam descends in one of the branches of said sections B, passes under its bend *B*¹, and ascends into the second branch thereof to its top opening, through which it passes to enter another section, and the operation is repeated until it reaches the bottom of the end section C, from which it passes, with the water of condensation, into the discharge or return pipe *c*.

FIG. 1.

FIG. 2.

To produce a steam-tight joint presenting a large surface for the paint, cement, or substance between the faces of the sections at the point of junction, these faces are provided with a series of concentric grooves *d*, substantially U or V shaped in cross-section and arranged so as to become interlocked when two radiator-sections are brought together in position to be united. These sections may be united together by bolts passing above their bends; but they may be located near the centre of the bearing-surface and to conceal said bolt and dispense with packing under its head and nut, and prevent water or steam from leaking out of the radiator at these points, it is placed entirely within the sections, as shown at D.

To form a rest for the head or nut bolt, the opening in the lower end of the end sections has a partition, formed with said sections, and to permit the water of condensation to escape said partitions have openings above the level of the bolt. To prevent, also, the steam from passing through the openings from the bottom of the section A to the section B, there is placed a pendent gate or steam-seal *g*, made of thin sheet-metal, that is retained between the inner edges of the grooved surfaces.

The washer *G* has concentric grooves *d'* on both sides of its face to become interlocked with the grooves *d* upon the joints of the radiator-sections.

Figure 2 shows the method of joining two sections or elements at the top.

MAN-HOLE AND TUNNEL FOR HOUSE-TRAP AND PIPES OUTSIDE WALL OF BUILDING—

FIGURE 1.

clear, with brick sides and flagged top, manholes being arranged in the lawn through which it can be entered and ventilated. The trap is set in the first manhole close to the house; the size of this shaft being 3'3"x3'3", and the top closed by a flag with cast-iron manhole cover.

FIG. 2.

The sewer-pipe through the tunnel and grounds is ventilated at this point by a pipe carried up within the building to the highest point of its roof. The sewer, house-drain, and trap are five inches in diameter, and the sewer-vent, just mentioned, and the foot-vent are four inches in diameter. A 4-inch pipe from the position of the foot-vent also extends to the roof alongside the sewer-vent. The arrow on this pipe is shown as though the air-current was down, to supply the foot-vent. This may be so, but the principal object of the pipe is to establish an equalization of pressure between the atmosphere within and without, no matter which way the preponderance may be.

Figure 2 shows how the tops of all the vent-pipes are arranged on the roof. The roof is copper, and it was provided that a hub of the pipe would in every case be so

cross that comes at the top level being closed with a screw-plug, as is also the end that projects 2 feet 6 inches or so above the water. From the top or grease level to the

FIG. 3.

edge of the $\frac{1}{2}$ bend under which the clear water flows off is about 15 inches.

(TO BE CONTINUED.)

MONTREAL PLUMBERS TO ORGANIZE A TRAINING SCHOOL.

A WELL attended and representative meeting of the master plumbers of Montreal was held in the rooms of the Montreal Contractors' Association, 99 St. James Street, last week under the following resolution:

Preamble.—The Master Plumbers of Montreal, feeling that the best interests of the general public and themselves will be promoted by an organization having for its object the raising of the standard of the trade and those working at the same,

Resolved, That it is desirable to organize the section of the plumbers, gas, steam, and hot-water fitters in connection with the general association known as the "Montreal Contractors' Association."

Objects.—The objects of the members of the said "section" shall be the promotion, in their fullest and truest sense, of the moral, mental, mechanical, and social welfare of those connected with the different trades, forming or connected with those comprising the membership of the said "section."

FALL OF FIVE DERRICKS AT THE NEW COURT-HOUSE, BOSTON.

ON Wednesday of last week one of the large derricks in use at the new Court-House in Boston fell, dragging down four others with it, and slightly injuring three men of the 150 at work on the building. The derricks are six in number, capable of raising from four to five tons at the end of the boom. The masts are from 70 to 86 feet high and the boom from 55 to 65 feet long.

The mast is formed of a 14x12-inch timber. Where the boom is attached the mast is reinforced by a 12x12-inch

iron is attached to each timber, forming a loop from which a tension rod passes up to the mast-head. On the booms of some of the derricks there are two such loops. A traveler of hard wood slides on the boom and the load is suspended from it.

The four derricks first erected at the northern end of the building were connected together at their heads by 4-inch wire spring-stays, and had guys to adjacent buildings and to posts in the streets. The hoisting-rope on these derricks passed through the foot-block down to a snatch-block situated near the ground, thus making the

transverse pieces were bolted on either side of each wall. For additional support two inclined posts were placed just below the foot-block. The accident happened when a load of some 2 or 3 tons was being raised. The strain on the hoisting-rope and the leverage of the weight on the boom drawing against one of the inclined posts caused the foot-block and cross timbers to be raised off of the brick-work, and the two cross timbers pivoted around on this one post until they got off the wall, the lower transverse pieces tearing out the brick-work on the inside of the wall only, and the whole derrick came down almost vertically, crushing the two cross timbers. The boom was splintered by falling on a granite wall. The shock pulled over four of the other derricks and snapped off a post to which some of the guys were fastened. The mate to this derrick remained in place almost erect, with no damage. Of the other derricks one mast was snapped in two and four booms broken. Had the walls not been built up so high and so close together as to form a sort of enclosure around the four northern derricks, not only would they have been entirely smashed, but the brick-work would have been much more damaged, and probably there would have been more casualties.

As it is the guys got snarled up and let the derricks over quite slowly on the walls, which were damaged only where actually struck and can be repaired with very little labor.

Several of the derricks were idle at the time, so that two days sufficed to rig up the others and very little delay was caused.

The derricks were laid out by Mr. Clough, the architect of the building, and are after the pattern of the Norcross derrick, so called, except that the masts being very long are spliced in the middle and that the traveler has no rollers.

They have proved very strong and useful. But this accident shows the necessity of having a snatch-block under the derrick and independent of the foot-block, so that all the strain of the hoisting rope shall be vertical on the foot of the derrick.

[The foregoing description and illustrations from our Boston correspondent show very clearly the construction of the derricks and the cause of their fall. While the construction of the derricks had nothing to do with their fall, it should be pointed out that they could have been made stronger with less material had a single horizontal strut been set opposite to and at the same height as the boom to transfer the thrust of the boom directly to the truss-rod and thus relieve the mast of all transverse strain. Perhaps this could have been done even better by continuing the boom itself back past the mast until it could receive the support of the truss-rod. This would do away with the two present horizontal struts and the reinforcing timber, as only small splice-plates would be required at the joint in the mast which now comes directly opposite the thrust of the boom and hence in the worst possible place.]

Gas and Electricity.

Correspondence.

All correspondents should send us their names and addresses, not necessarily for publication, but as a guarantee of good faith and because it is often necessary to communicate with them for additional information before printing their communications. Anonymous letters will not be noticed.

A TACHOMETER WANTED.

SIR: Can any of your readers state where a current-meter or tachometer can be had (meter for measuring the velocity of water-currents)? ENGINEER.

If our correspondent who signs himself "Engineer," from Reading, Pa., will send us his full name and address, we will reply to his question on steam-heating apparatus of November 5, attached to which is a drawing bearing date of October 30.—ED.

PAINTING ROOF SO THAT DRINKING WATER COLLECTED FROM IT WILL NOT BE INJURED.

STAMFORD, CONN., November 9, 1887.

SIR: My house has a shingle roof from which water is collected in a cistern. This water is used for drinking water.

Can the roof be painted, and, if so, please inform me what paint can be used that will not injure the water?

Yours truly, H. L. UNDERHILL.

[We have used the ordinary iron paint for a tin roof under such circumstances. The paint should not contain lead. Whatever paint is used, the water from the roof for the first two or three days should not be allowed to flow into the cistern, but be run to waste to get rid of oil and sediment.]

THE SENECA FALLS WATER-WORKS.

THE following letter from a prominent citizen of Seneca Falls, regarding the terms on which the town contracted with Mr. Norman for a water-works, is of interest. From this it would seem that if the town did not get much they did not expect much, nor have they been inclined to spend much money:

SENECA FALLS, N. Y., November 14, 1887.

SIR: The water-works project had previously been discussed and voted upon in this town until the citizens were opposed to any contract or option at all. So that these works were built at the entire risk of the builder. The only condition was: he was granted permission to lay his mains in the streets, and required to make the road-bed as good as he found it. There have been no hydrants taken by the town, although a public sentiment was gradually working up in favor of taking hydrants in certain places.

A few of the citizens have distrusted the efficiency of the cement pipes, and suspected that the whole thing was a cheap job intended for sale. Suspicion was strengthened by the fact that the place of water-supply is not the best, although it is the cheapest. But the general sentiment is one of confidence in the man and sympathy with him in his loss.

PREVENTION OF FIRE IN THEATRES AND PUBLIC BUILDINGS.

WE are asked by the city engineer of an English city as to what regulations exist in New York or other American cities relative to precautions adopted for prevention of fires in theatres and public buildings. He states it is reported that in some States automatic sprinklers are required by law to be provided, and would like information on the whole question as to the practice in the United States. We shall be obliged for any data or copies of regulations our readers can furnish.

THE IMPORTANCE OF WETTING BRICK BEFORE LAYING.

SHARPSVILLE, MERCER COUNTY, PA., }
November 14, 1887.

SIR: Editorially remarking upon "The Fall of the Parochial School Building in Harlem," in your issue of October 22, you say, "The causes of the disaster are sufficiently set forth" in the report of the Superintendent

of the Building Bureau, and quote from that report six specifications charging, respectively, use of poor or insufficient material, faulty architectural construction, and reckless, and every way bad, practice in building.

The first of these specifications charges that the mortar, used in the building in question, was of but "medium" quality. Mr. Martin, Inspector of the Harlem District, has, since the fall of the school-house, reported the mortar to have been "first rate" in quality. But, arguing from the fact that you could nowhere find any mass of fallen brick held together by the mortar (the brick having fallen "clean," as you state the matter), you assert, "medium is a very mild term to apply to this mortar," and you leave your reader to infer that the mortar was not even of moderately good quality.

You do not say that you actually inspected the mortar (of which you might have found a sufficient quantity in the mixing beds, no doubt). If you did so, you can, presumably, state the proportions of the mixture, and if the mortar was actually "poor" (Mr. Martin to the contrary notwithstanding), that fact is, of course, important in the case. But the simple facts that the bricks were not cemented together by the mortar, and that (therefore) they fell "clean," are not sufficient evidence that the mortar was not of "first rate" quality.

Mortar made of the best possible admixture of good lime and sharp sand is, in cementing effect, of but little more value than mud, in cases where the bricks "laid" in it are (practically) perfectly dry when laid.

A common brick, which when "dry" weighs 4½ pounds (seventy-two ounces), if kept thoroughly wetted for an hour or two will absorb about twelve ounces, or about seventeen per cent. of its own weight of water. Such brick, laid in wall without previous thorough wetting, will speedily absorb practically all the moisture of the mortar, leaving the "mortar" but little, and sometimes not any, cementing virtue. If a wall constructed, as aforesaid, of dry brick, be thrown down, the bricks will fall "clean," evidences of good cementing will be rare. I do not know what is the general practice in and about New York in the matter of wetting brick as preliminary to laying them; but I do know that this treatment (of wetting), so necessary to proper results in cases of work done in dry weather, is in most parts of the country largely, if not entirely, omitted or shirked.

J. M. GOODWIN, Mem. Am. Soc. C. E.

[In reply to our correspondent, we would say that by the use of the word "clean," we meant all that it could imply in that connection—namely, that the fallen bricks were not merely separate from each other, but that no mortar adhered to them, which we considered a sufficient indication of its character. We have, in freezing weather, had brick laid without wetting and with fairly satisfactory results, though, of course, in that case there should be more water in the mortar. Without further experiment we are inclined to doubt whether really good mortar would merely, by being used with dry bricks, be as entirely deprived of its adhesive properties as was the case here.

We confess, however, that we had not in this instance thought of any possible neglect in wetting the brick before laying, as it is the universal custom in this city, being specially required by the building law, and as water must always be had for mixing the mortar, and is usually obtained through a hose from a hydrant or street-washer, the additional labor of wetting the bricks with the hose is so slight as to be seldom, if ever, neglected.

We are glad that our correspondent should have called attention to this important matter, doubtless, as he says, often in many places "omitted or shirked," and from early experiments of our own we can corroborate what he says about the absorption of water by dry bricks. Bricks, however, should not be saturated, as in that case they do not "suck on" to the mortar, and are apt to slip when laid; also, the excess of moisture softens the skin of the bricklayer's fingers so that they soon get worn and sore. We should be glad to hear from others who may have had experience in laying bricks without wetting, from cold weather or other causes, and in this connection the result of the experiments on the addition of salt to cement when used in freezing weather, which we give in another column, may be of interest.]

THE LESSON OF THE SENECA FALLS AND FRANKLIN STAND-PIPE DISASTER.

SIR: The fall of two water-towers built by a contracting engineer should call the attention of corporations or individuals who intend erecting works of any kind to the necessity for skilled supervision which has no pecuniary interest in the profits of the contractor.

A habit has grown up by and through contractors', who are anxious to take greater or less risks for the sake of economy, offering to advance a certain amount of capital and do their own engineering. It is not alone the ignorant, and possibly sometimes venal, selectman or village trustee that finds himself unable to resist the twofold bait, but

large railroad corporations are often guilty of sacrificing, to a greater or less extent, the interests of their stockholders by virtually making their contractor their chief engineer.

The village magnate, possibly a small lawyer or worthily engaged in the retail sale of tape or sausage, may be pardoned for not seeing through the declamations of the would-be contractor who, it may be, has had some small practice in his profession or has an engineer associated with him, and may believe that he really does know more than all the engineers put together (he surely will not find any engineer claiming so much); or that engineers are a nuisance and unnecessary expense on work where there is an intelligent contractor who has a large pecuniary interest, say one-half the expected profits, in the success of the work.

But any business man who allowed an agent to be the sole auditor of the accounts presented for his expenditures would meet small sympathy for his losses. Nor would, in general, an agent be employed who urged as a condition of employment the privilege of being such sole auditor. The corporation which allows a contractor to take its work on his own specifications, to be executed under his own supervision, seems about as wise as the man who gave his debtor the note just signed—so that he could remember when it became due.

While the practice of unwatched contracting in all branches of construction is far too prevalent in this country for either stability of structure or safety of life, it is exhibited in its worst forms in the construction of water-works for small places, where constructing firms, with their command of capital, approach towns and villages with offers to build and operate water-works on terms which often read like the bargain of the horseshoer, only there is no limit to the nails. While much of the work done by these firms is of good quality, some of it is undoubtedly of very poor material and design, and usually the intention is to derive the maximum revenue from the minimum supply of water.

If you, Mr. Editor, agree with me that supervising work, in the cheapness of which the supervisor has a direct pecuniary interest, brings too heavy a strain on human nature, and that the proposition to do so is almost *prima facie* evidence of an intention to take undue advantage, I hope you will give the influence of your paper, already noted for the good work it has done in this direction, to the thorough exposure and condemnation of the practice. C. E.

LONDON CORRESPONDENCE.

A Tramway Locomotive—Management of English Technical Schools—Boiler Inspection—Lighting Buoys by Gas.

A NEW form of tramway engine has lately been tried on the West Brighton and Shoreham Tramway system. It is from the design of Mr. Alfred Greig, of Leeds, and built by Aveling & Porter, Rochester. The special feature in the engine is that the cylinders and working parts generally surmount the boiler, the object being to minimize the introduction of dust, mud, etc., which of course obtains very largely with the usual type engine carrying the working parts below the boiler, to the shortening of life in the working parts. The dimensions of the engine are 11'6"x5'8"x9'6", carrying a locomotive type of boiler, with working pressure of 180 pounds. There are two 5½-inch cylinders with 10-inch stroke, and the connection with the driving axles is by spur gearing: the power is taken from a pinion on the crank-shaft to an intermediate wheel, geared into other wheels, thence to the axles. The engine has an automatic brake to shut off steam directly a speed of nine miles is attained. A Blackman propeller, driven by an auxiliary engine, passes a current of air over the tubes of a condenser, through which exhaust-steam is passed. The engine is stated to work very satisfactorily.

The value of schools for technical education is being very generally recognized. Professor Sylvanus P. Thompson, speaking at St. Pancras a few days since, drew a very unfavorable comparison between the technical schools of England as against those of Germany and other countries. He expressed an opinion that in the present state of deficient technical education Englishmen ran a great risk of having the bread taken out of their mouths by foreign workmen. The professor might have preached also on another text, showing that when good technical schools are instituted, it is well to expend a *fair proportion* of the total expenditures on the teachers, as against the building and administrative staff. In at least one branch, under the City Guild's Institute, the remuneration is absurd and totally inadequate; so low indeed as 4½d. (9 cents) per hour.

The English Board of Trade have prepared a bill which was read a first time during last session giving the neces-

sary powers for the supervision of boilers. It has long been admitted that such supervision is necessary, but it is difficult to see why a clause is inserted exempting boilers in vessels classed as Lloyd's or having passenger certificates. It is just as necessary, indeed if not more so, that such boilers should be subjected to inspection as those that are on land.

A correspondent of the *Times* gives the following information respecting the manufacture and supply of gas for lighting buoys in the various channels, under the system of Pintsch's Patent Lighting Co. The gas used is made from once refined paraffine subjected to special treatment and purification when made. It has an illuminating power of 45 candles when burnt in the London standard burner. The cost of the gas is from 8s. to 11s. per thousand cubic feet. In its manufacture for the purpose of buoy work, a small gas-works at some accessible distance in the locality is necessary. The oil is vaporized in cast-iron retorts and carried off as gas to a small gasometer. The necessary superficial area for the purpose is about 40x16 feet. From the gas-holder it is forced into cylindrical holders at a pressure of 150 pounds to the square inch. It is forced into strong cylindrical holders of the capacity of 3,700 feet of gas compressed into a cubic space of 370 feet, and served into the holders at a pressure of 150 pounds. Two of these holders are conveyed from the gas-works to the buoy which requires replenishing, and the gas is served thence into the buoy's receiver by an automatic regulator, the outflow of the gas from the buoy being controlled so that it issues at the burner at $\frac{1}{16}$ water column pressure.

THE CHICAGO DRAINAGE COMMISSION.

CHICAGO, ILL., November 5, 1887.

To Hon. John A. Roche, Mayor.—Sir: In accordance with your instructions, the work of the Drainage and Water-Supply Commission is now closed. The interpretation that your honor has deemed proper to place upon the action of the Council of January 27, 1886, under which the work was undertaken, is that the object of the same has now been practically accomplished—viz., the determination of the best general plan of future sewage disposal for the city of Chicago, it being assumed that the collection of further data and the preparation of details should be postponed until it has been decided to execute the problem.

The interpretation placed upon the same by the preceding administration, which has guided and limited the scope of the investigation, was that all phases of the subject should be investigated not only in their general aspects, but in sufficient detail to render it possible to give close comparative costs of the different schemes of sewage disposal which were being urged, and that the reasons for accepting or rejecting any plan should be set forth in detail, the work marked out being not merely affirmative, but negative, to the extent which should be necessary to finally clear the ground of all incumbrance. Hence the study of these projects has been prosecuted on a scale to enable the commission to "report on the whole matter committed to it in the most full and comprehensive manner," which are the terms of the resolution.

While satisfied with the conclusions presented in our preliminary report of January, 1887, and while without hesitation we recommended the disposal of the sewage into the Mississippi Valley, diluted with a large amount of water from Lake Michigan, and the taking of the lake water for domestic consumption at points opposite the city; while we are satisfied as to the advisability of diverting the flood water of the Desplaines River as a part of the plan of future sewage disposal, as set forth in a supplementary report of July, 1887, we are not prepared to make a final report in obedience to the action of the council for reasons which we respectfully submit for your consideration.

And we cannot refrain from expressing our decided conviction that when the present employees go out they will carry with them a large percentage of the results thus far gained greatly to the loss of the city, because much of the matter will have to be taken up *de novo*, which can only be prevented by having them complete their unfinished tasks.

To close the investigation at the present time will prejudice our cause in all the towns and cities which are affected by our sewage disposal or are interested in a navigable waterway to the lakes. Chicago will be weak against

opposition in Congress this winter, and will not be able to present a technical case before the board of United States engineers likely to be appointed, and will be in danger of failing to secure needed State legislation. In addition to this the sanitary needs of the city are pressing, and will be urgent before the remedy can be applied. We are convinced that we would be culpable if we acquiesce in the abandonment of the investigation without expressing ourselves with the strongest possible terms in the negative.

The subjects of the most vital importance, requiring further investigation in order to fulfill the objects for which the commission was created, are as follows: The pollution of the main waterway and the necessary dilution which should be secured. The physical effects upon the Desplaines and Illinois Rivers of turning a large quantity of water from the lake into their beds in addition to that already carried. The study of the velocity of water in the proposed channels as to the economic construction of the same, and its effect upon navigation. Finishing all maps and plans and the compilation of all data and their presentation in a systematic report for permanent use.

We are of the opinion that these questions could be answered by the end of next spring with the expenditure of not more than \$20,000 for chemical analysis, salaries of some additional men and the present force, which consists of Mr. L. E. Cooley, Principal Assistant Engineer, and Messrs. Johnston, Feind, Ericson, and Lydon, assistants, of whose industry and ability we desire to make special mention. Respectfully submitted,

S. G. ARTINGSTALL, RUDOLPH HERING,
BENEZETTE WILLIAMS, Chief Engineer.
Consulting Engineers.

THE ENGINEERS' CLUB OF ST. LOUIS.

The club met November 20, President Potter in the chair, W. H. Bryan, Secretary, nineteen members and one visitor present. The Executive Committee submitted the following report on programme, which was adopted:

ST. LOUIS, November 2, 1887.

GENTLEMEN: Your executive committee beg leave to submit the following programme of the club's work for the coming year. Meetings have been arranged for the first and third Wednesdays of each month up to June next. It is not expected that this plan can be rigidly adhered to, but it will serve as a basis to work upon, and will be followed as closely as circumstances permit:

November 2.—Charles E. Jones, "Steam-Heating at Washington University."

November 16.—Prof. J. B. Johnson, "Testing the Strength of Engineering Materials."

December 7.—Annual meeting.—P. M. Bruner, "The Action of Frost on Concrete Work."

December 21.—Isaac A. Smith, "Rapid Railway Embankment Construction."

January 4.—Charles H. Ledlie, "Construction of Dam and Reservoir at Athens, Ga.," Charles W. Bryan, "Railway Bridge Designing."

January 18.—Carl Gayler, "Floors of Street Bridges"; N. W. Eayrs, "The Improvement of Nantucket Harbor, Mass."

February 1.—Professor F. E. Nipher, "Graphical Solution of the Action of the Series Dynamo"; B. F. Crow, "Constructive Accounts."

February 15.—Robert Moore, "Sizes of Railroad Culverts"; O. L. L. Petitdidier, "Practical Notes on Masonry and Stone Laying."

March 7.—Professor H. B. Gale, "The Transmission of Power by Belting"; Samuel F. Burnet, "Cement and Mortar."

March 21.—Professor W. B. Potter, "St. Louis Water-Supply."

April 4.—S. Bent Russell, "Thickness of Water Pipes"; H. A. Wheeler [subject not yet announced].

April 18.—Professor C. M. Woodward, "Gas Producers"; Lewis Stockett, "A Well-Ventilated Mine."

May 2.—Colonel E. D. Meier, "Standards of Boiler Efficiency"; Charles F. White, "The Failure of Firm-nich Boiler."

May 16.—R. E. McMath, "The Waterway Between the Lakes and the Mississippi River."

June 6.—M. L. Holman, "The Temporary Low Service Pumping Plant at St. Louis."

Partial promises have been made of other papers on topics of interest. These will be presented as opportunity occurs and due notice given.

Six applications for membership were received.

Professor Johnson read a communication from the Board of Managers of the Association of Engineering Societies, on the subject of a closer union between the societies now in the association and others. The consideration of this paper was made a special order for the next meeting, November 16.

Mr. Charles E. Jones then read a paper on "Steam-Heating at Washington University, and Experience

Underground Pipes." The history of the system in use was given with details of its construction and the work done. It was shown that the boilers were regularly doing double the duty which was originally expected of them. The evaporative efficiency did not seem to be reduced when the boilers were forced in this manner. Great efforts had been made to reduce the smoke and many devices had been tested. All had failed on account of the excessive duty required of the boilers. The underground pipes had failed after three years of service from external corrosion due to the accidental admission of moisture to the conduits. New pipes had been laid recently and the construction of the new conduit was shown.

Professors Woodward, Potter, Gale, and Messrs. Bryan and Sharman took part in the discussion. Mr. Jones added that a new stack had just been erected, which had increased the draft sufficiently to permit the introduction of a small amount of air above the grates. This had resulted in an appreciable reduction of the smoke.

WILLIAM H. BRYAN, Secretary.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

The eighth annual meeting (XVIIIth) of the American Society of Mechanical Engineers will be held in the city of Philadelphia, Pa., beginning Monday evening, November 28, and ending Friday, December 2. This has been chosen by the council under the rules, to suit the convenience of those who might wish to visit Eastern homes for Thanksgiving, and who can thus attend the sessions on the same trip. The opening session is put down for Monday to admit of the most profitable use of time.

The business sessions of the convention will be held in Parlor C, of the Continental Hotel, corner Ninth and Chestnut Streets. The headquarters and secretary's office will be at Room No. 27 on the first floor.

The Continental will give special rates to members, as follows: \$2.50 and \$3 per day, excepting on first and second floors, where the rates will be \$4 per day. Rooms with bath will be charged for at \$1 per day additional, whether occupied by one or two persons. Fires will be fifty cents per day. It is hoped for the sake of social intercourse and professional profit that as many as possible will stop at this house.

The programme of sessions is as follows: Monday evening, November 28, at 8 P. M., first session, president's annual address.

Second day, Tuesday, November 29, at 10 A. M., business session, reports of committees and general administrative detail. After these the professional papers will be taken up. The afternoon will be left free for members to visit different manufacturing establishments who have extended invitations.

In the evening, at 8 P. M., third session for professional papers and discussion.

Third day, Wednesday, November 30, at 10 A. M., fourth session for professional papers and discussion. Fifth and concluding session at 2:30 P. M. These sessions will be in Parlor C, of the Continental Hotel.

On Wednesday evening, a reception is tendered to the society at the Academy of Fine Arts, being the occasion of a private or first view of a special collection of portraits, together with the regular pictures of the academy.

Fourth day, Thursday, December 1, excursion by special train to Bethlehem, Pa., leaving by P. & R. R. R. at 9:15 A. M., returning to reach the hotel at 5 P. M. This visit will be to the new plant of the Bethlehem Iron Co.; also to the Lehigh University and to the Lehigh Zinc Works. In the evening a complimentary dinner will be given to the members by citizens of Philadelphia.

Invitations have been received from the following establishments and institutions to visit them during the sessions of the society:

Bethlehem Iron Company, Bethlehem; Lehigh Zinc and Iron Company, Bethlehem; Pennsylvania Steel Company, Steelton; Henry Disston & Sons, Tacony; Baldwin Locomotive-Works, City; Bement, Miles & Co., City; William Cramp & Sons Ship and Engine Building Company, City; I. P. Morris & Co., City; William Sellers & Co., City; Southwark Foundry and Machine Company, City; Williamson Bros., City; Kensington Engine-Works, City; Otto Gas-Engine Works, City; Pennsylvania Museum and School of Industrial Art, City.

The following papers are to be presented and discussed at this meeting:

Lewis F. Lyne: "The Use of Kerosene Oil in Steam-Boilers."

Henry I. Snell: "Method of Ventilating and Heating Office and Warehouse."

John E. Sweet: "A New Principle in Piston Packing."

R. H. Thurston: "Internal Friction of Non-Condensing Engines."

John J. Grant: "The Milling-Machine as a Substitute for the Planer."

Henry I. Snell: "Centrifugal Fan-Blowers and the Power to Drive them."

John Coffin: "Steel Car Axles."

Oberlin Smith: "Power Press Problems."
 Frank Van Vleck: "Standard Section Lining."
 Percy A. Sanguinetti: "Divergencies in Flange Diameters in Pumps, etc."
 William O. Webber: "Centrifugal Pump Efficiencies."
 Gaetano Lanza: "Friction of Toothed Gearing."
 Jerome Sondericker: "How to Test Strength of Cements."
 H. deB. Parsons: "Influence of Sugar upon Cements."
 James M. Dodge: "New Method of Stocking and Re-loading Coal."
 E. C. Felton: "Results Obtained from Steel Tested Shortly After Rolling."
 O. C. Woolson: "Road-bed for Railroad Bridge Structures."

Subjects and Queries will also be presented for the Topical discussions, which have proved so interesting and profitable at the recent meetings. The Secretary will be glad to receive any written discussion of any of them from members who cannot attend the meeting. Such communications will be read at the meeting as part of its proceedings.

Special railroad rates have been secured for this meeting under the certificate plan. By this scheme the members pay full fare coming to the meeting and have a certificate of such payment signed at the starting point. On the presentation of such certificate, indorsed by the Secretary, at a Philadelphia ticket-office, they receive their return-ticket for one-third the regular rate. Members buying tickets west of Pittsburg and Wheeling will obtain their certificates from the ticket-agent at the starting points. Members starting east of those points will receive the certificates and instructions from F. R. Hutton, Secretary, 280 Broadway, New York.

THE FALL OF AN L-ROAD ERECTING-CRANE.

THE traveling crane used by the Pencoyd Bridge Company in erecting their elevated railroad work on Flatbush Avenue, Brooklyn, fell to the ground early on Wednesday morning last, with the two longitudinal girders on which it rested.

The accident seems to have been due entirely to a lack of care or skill on the part of the foreman in charge of the work in two particulars. In the first place, the crane was used while its front or bearing end was on the middle of a span instead of over a transverse girder, as it should have been; and second, the centre boom, some sixty feet long, was used to lift a heavy weight at some distance to one side of the structure, which brought most of the weight of both crane and load on the centre of one of the two inner girders on which the crane traveled. It was a case of "more haste less speed." The foreman is understood to have been trying that day to make a record, and made a wreck instead. *Festina lente.*

The platform of the crane broke in two over the transverse girder between its front and rear bearings, so that the boiler on its after part fortunately did not fall, and its explosion was not added to the general ruin.

Perhaps if the front of the crane had been wide enough to get a bearing on the two outer girders as well the accident might not have occurred. Another contributing cause may have been the lack of lateral bracing between the longitudinal girders on which the crane traveled. This cannot well be put in permanently until after the crane has passed, and the temporary wooden substitutes are not always reliable.

The fractured metal of both crane and girders seemed of excellent quality.

The crane was designed by Mr. C. C. Schneider, Mem. Am. Soc. C. E., and Chief Engineer of the Pencoyd Bridge Company, and was a very complete affair, having three booms and so arranged as to erect all parts of the structure.

We have for some time contemplated giving our readers a full description of it, such as we have already given of the erecting-crane used by the Phoenix Bridge Company on the Kings County Elevated Road, and expect to do so in our next issue.

Fortunately, as has been the case in all the accidents we have chronicled during the last few weeks, no one was seriously hurt, although there was the usual narrow escape, a crowded horse-car having barely passed under the crane before it fell.

We trust this series of instructive accidents will not culminate in some frightful tragedy; but the good fortune that has hitherto attended them cannot be expected to continue, and if THE ENGINEERING AND BUILDING RECORD has any heedless or ignorant readers, let them be warned to be wise in time.

THE SENECA FALLS STAND-PIPE.

Mr. JOHN F. WARD, a civil engineer, of Jersey City, who has had large experience in water-works construction, in a communication regarding the failure of the stand-pipe at Seneca Falls, suggests, as a possible solution of the failure, that, when the tank was being erected, there were no proper precautions taken to prevent the straining of some of the sheets by the action of the wind. In putting up the first four or five courses of these sheets, which were presumably about nine feet long by five feet high, they were doubtless held in place by temporary bolts, and the action of the wind at night might cause a fracture that would not be noticed by the workmen the next day. He recalls a similar experience with a tank some years ago, in Cincinnati, due to this cause. If this is so it is only another argument for the necessity of skilled supervision of the erection of structures of this character, and especially when steel is used.

OUR correspondent in Springfield sends the following further information regarding this stand-pipe:

"Regarding the failure of stand-pipe at Seneca Falls, Mr. R. F. Hawkins, who built it, informs me that the construction was carried out in accordance with specifications furnished by Mr. Norman, the work being directly in charge of a Mr. Cunningham, who acted as engineer for Mr. Norman. Mr. Hawkins informs me further that the failure of the stand-pipe was probably due to the giving away of the bottom plate near the outlet-pipe, which he thinks was caused by the foundation."

THE ENGINEERS' CLUB OF PHILADELPHIA.

THE club met on November 5, President T. M. Cleemann in the chair, Howard Murphy, Secretary and Treasurer; seventeen members present.

The following were elected active members of the club: Messrs. Henry I. Snell, Henry B. Seaman, Frank Cooper, Arthur H. Wood, Erwin Graves, I. H. Wainwright, and Fred. J. Amweg.

The Secretary called attention to the fact that the 17th of December of this year would be the tenth anniversary of the organization of the club, and recommended that it be observed by the holding of a reception in the club house on that evening. After some discussion the following resolution, offered by Mr. John T. Boyd, was unanimously adopted:

Resolved, That a committee, with power to act, be appointed to take charge of a decennial anniversary reception, to be held in club house on December 17, 1887, at 8 o'clock P. M.; said committee to consist of as many members as chair may decide, who shall issue cards of invitation, given on request of members, the latter to be entitled to invite not exceeding three members of the engineering or architectural professions, all members being requested to subscribe two dollars by notice sent by the secretary, and that such other invitations may be issued as the committee shall deem proper and desirable.

Mr. Boyd was unable to serve on the committee, which the President appointed as follows: Percival Roberts, Jr., Chairman; E. V. d'Inville, Prof. L. M. Haupt, C. G. Darrach, Frederick Graff.

Mr. C. G. Darrach presented a paper upon "Boiler Specifications," which was discussed at length by Messrs. John T. Boyd, Charles T. Thompson, A. Marichal, J. E. Codman and others. At a late hour it was decided that the discussion be continued, and that such copies of the specifications as the authors could supply be sent to such members as would probably take part in the discussion.

THE ENGINEERS' CLUB OF KANSAS CITY.

A REGULAR meeting of the Engineers' Club of Kansas City was held November 7. There were present Messrs. W. B. Knight, A. J. Mason, E. B. Kay, A. E. Swain, C. E. Taylor, S. A. Mitchell, T. F. Wynne, E. W. Stern, Clift Wise, Kenneth Allen, Secretary, and five visitors. Mr. Wynkoop Kiersted was elected a member.

The Secretary read a letter from the Executive Board of the Council of Engineering Societies inviting co-operation.

The President was directed to appoint a committee of three to act in conjunction with the other committees of the Council.

The President appointed Messrs. Chanute, Breithaupt, and Wise. Victor M. Witmer was proposed by E. B. Kay as associate member. Mr. Wynkoop Kiersted read a paper on "Water-Supply and its Development for Small Cities in the West," which was then discussed.

THE AMERICAN SOCIETY OF CIVIL ENGINEERS.

A MEETING for the reading and discussion of papers only was held Wednesday evening, November 16, the President, William E. Worthen, in the chair, and, in the absence of the Secretary, the papers were read by Mr. Theodore Cooper. The first paper was on "Experiments Upon Z-Iron Columns," by C. L. Strobel, M. Am. Soc. C. E. The next paper was by A. P. Boller, M. Am. Soc. C. E., on "Test of a Wrought-Iron Double-Track Floor Beam." A chart illustrating the different wire gauges in use was then exhibited and explained by S. S. Wheeler, Jun. Am. Soc. C. E. Abstracts of these papers and of the interesting discussions which follow them will, for lack of space, have to be deferred to our next issue.

BOSTON SOCIETY OF CIVIL ENGINEERS.

THE regular monthly meeting of the Boston Society was called to order at their rooms November 16, by Vice-President F. P. Stearns. After the regular business had been attended to the members were favored by an account of the plant of the Boston Heating Company, given by A. V. Abbot, Chief Engineer of the National Superheated Water Company, of New York. The remarks were illustrated with a small section of the pipes and fittings as laid through the streets and houses. There were 58 members and 26 visitors present.

THE EFFECT OF FROST ON CEMENT RESISTED BY SALT.

PH. DELAHAYE, in the *Revue Industrielle* of November 3, describes some experiments recently made in Germany, on the action of cold on hydraulic cements. The stones used were 2½-inch cubes. Some of the stones were joined with cement mixed with pure water, others with cement mixed with water which contained two per cent. of salt, and others again with cement mixed with water containing eight per cent. of salt. While the cement was still fresh the stones were placed out of doors, and left exposed twenty-one days in a cold of 20° to 32° Fah., after which the stones were kept in a warm room for a period seven days. At the end of this time it was found that the cement mixed with pure water was completely disintegrated and had no holding power. The cement containing two per cent. of salt was in a better condition, but not good. Whereas the cement the water of which had had eight per cent. of salt had not suffered in the least.

JAMES B. SNIFFEN.

THE many friends of Mr. James B. Sniffen, for many years connected with The Meyer-Sniffen Co., Limited, will be pained to hear of his death, which occurred on the 17th inst., at Brooklyn, N. Y.; a malignant attack of malarial fever being the cause. He is to be buried to-day at White Plains, N. Y.

PERSONAL.

CAPTAIN L. E. CAMPBELL, U. S. A., has been transferred from Fort Leavenworth, Kan., to Denver, Col.

COL. RUFUS SEXTON, Asst. Quartermaster-General, U. S. A., now stationed at Louisville, Ky., will shortly retire from active duty and settle at Germantown, Pa.

LIEUT.-COL. HENRY C. HODGES, Deputy Quartermaster-General, U. S. A., in charge of General Depot of Quartermaster's Department at New York, has been ordered to relieve Col. Rufus Sexton at Louisville, Ky.

DR. WILLIAM O'GORMAN, a prominent surgeon, died in Newark, N. J., recently, aged sixty-three years. He was born in Ireland and graduated there, but came to this country in 1849. He was Chief of New Jersey Medical staff during the war.

D. W. C. PERRY, Chief Engineer of the Kansas City and Pacific Railroad, spent last week in New York. He reports that his company has constructed about 100 miles of line in South-eastern Kansas, from the line of the Indian Territory north through Parsons and toward Paoli.

MR. J. H. STRIEDINGER, M. Am. Soc. C. E., has recently returned from New Granada, in Central America, where he has been engaged at railroad work and mining. His return is caused by the outbreak of a revolution. These revolutions do not facilitate engineering operations.

THOMAS C. BATES, a veteran railroad builder, died at Rochester, N. Y., on the 10th inst., aged seventy-five years. The deceased was actively engaged before the war in railroad construction in the South and he was chiefly instrumental in building all the railroads in Louisiana. He was a native of New Jersey.

R. E. BRIGGS, late Chief Engineer of the Mexican Central Railroad, has just completed the location of a new line of railway between Denver and Leadville, which will do away with the famous Georgetown Loop. The new line has six hundred degrees less curvature and is one and one-half miles shorter than the old line.

ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.

ON the evening of Tuesday, 15th inst., the Engineers' Society of Western Pennsylvania held their regular monthly meeting. The discussion on Mr. Ramsey's paper of the October meeting was continued by Messrs. T. P. Roberts, E. Koch, C. P. Buchanan, Jacob Reese, G. W. G. Ferris, Professor F. C. Phillips, and J. A. Brashear. Mr. C. P. Buchanan read a paper on some tests of steel beams which he has recently made in the interests of the P. C. & St. L. R'y Co. A committee was appointed to investigate and report upon the practicability of above or below grade crossings for railways entering the cities of Pittsburgh and Allegheny.

THE Arkansas Society of Engineers, Architects, and Surveyors organized an association on November 11, at Little Rock after a drive about the city. They enjoyed a banquet tendered them by the local committee and citizens of Little Rock. The local committee was: T. Harding, Chairman; Frank W. Gibb, Secretary; F. J. H. Rickon, B. J. Barlett, J. W. Cheek, J. H. Haney, James A. Martin, Henry G. Martin.

THE Connecticut Civil Engineers' Association held its quarterly meeting in Hartford, November 9. In the morning the members visited the new Commerce Street bridge and at noon took dinner at the United States Hotel. At the afternoon session a paper on the use of hydrants was read by C. E. Chandler, of Norwich, president of the association. Discussion of the paper followed and of the comparative merits and economy of hydrants with one or more nozzles on one branch and their effectiveness in case of fire. After this discussion the members visited the Asylum Street bridge and other points of interest.

MECHANICS' FAIR, BOSTON, MASS.
(Special Correspondence.)

THE Sixteenth Triennial Exhibition by the Massachusetts Charitable Mechanics' Association opened on the 17th of September and will close on the 26th of November. The fair is held in the Exhibition Building on Huntington Avenue and is easily accessible from all parts of the city. Thus far the fair has been well attended and is deemed a success. The railroads run excursion trains from the cities and towns in the vicinity, as well as from outlying States. Music is furnished during the day and evening. The building is open from 9 A. M. to 10 P. M.

While we notice many prominent New England manufacturers have not availed themselves of the opportunity of exhibiting their various products, there is a good general exhibit.

Among the exhibitors are:

The Jarvis Manufacturing Company, of Boston, showing feed-water heaters, improved power-pumps, and Armington & Sims engines in active operation, the main steam-pipes being covered by Gale & Childs, 134 Pearl Street, Boston, the New England agents for the magnesia sectional pipe-covering. The Hancock Inspirator Company, injectors and inspirators. George T. McLauthlin & Co., engines, elevators, boilers, etc. The Clinton Wire Cloth Co., of Clinton, Mass., wire netting and lathing for fire-proofing purposes. The New England Anderson Pressed Brick Co. show plain and ornamental building brick, trimmings, etc. The Gurney Hot-Water Heating Co. show hot-water heating apparatus for dwellings; visitors can see the apparatus in operation in the basement. The Gorton & Lidgerwood Co., of New York, house-heating boilers. The New York Exhaust Ventilating Co., ex-

haust-wheels for ventilating purposes. S. L. Holt & Co., Boston, portable and stationary steam-engines. The Wainwright Manufacturing Co., Boston, make a good exhibit of feed-water heaters, filters, four-way valves, corrugated tubing, expansion-joints, radiators, etc. George F. Holt, steam-engines and boilers. B. S. Williams & Co., the Manvel windmill. William Allen & Sons, Worcester, house-heating boilers. The Monson Slate Co., of Maine., show slate and slate products. B. F. Sturtevant, of Jamaica Plain, Boston, steam-fan. C. P. Coburn & Co., steam-pipe covering. John Post, Jr., & Co., steam-engines and centrifugal pumps. George G. Stillman, the Spencer automatic damper regulator. The Waterhouse Electric and Manufacturing Co. have a display of electric dynamos and lamps. Tyler Bros., of Boston, iron and steam boiler-tubes. The Dean Steam Pump Co., of Holyoke, have a large display of steam pumping machinery. Locke Bros., of Salem, Mass., show their steam-damper regulator. Henry W. Peabody & Co. exhibit the Hawkins hot-air system of heating and ventilation; also the Lowcock improved fuel economizer. The Adamanta Manufacturing Co. show their adamanta varnish gum, varnolio, an oil varnish manufactured from the same material for painters' use; also their adamanta enamel for iron pipe and adamanta rubber substitute specially adapted for electrical purposes. The Sanitas Manufacturing Co., plumbers' appliances. The Mason Regulator Co., governors, reducing-valves, etc. The Whittier Machine Co., of Boston, show valves for water, steam, and gas; they also have a George F. Blake Manufacturing Co.'s pump, run by a Daft electric motor, pumping pressure for the elevator; the motor is run by a Daft dynamo, run by the Ames' oil engine; the elevator is in constant use in the building. The Shipman Engine Co., of Boston, show an automatic steam-engine, using kerosene for fuel; consumption, a half a gallon an hour per horsepower; a three-horse-power engine running 33 16-candle-power lights from a Thomson-Houston dynamo; speed of engine, 390, and dynamo, 1,600 revolutions per minute; also running 5 2,000-candle-power arc-lights from a Waterhouse dynamo. The Washburn & Moen Manufacturing Co. show samples of wire of their own manufacture. The Bacon Boiler and Furnace Co., furnace for house-heating purposes. Sawyer & Blake, with the Edison Electric Illuminating Co., electric-motors in all sections. The Ashton Valve Co., safety-valves for steam-boilers. A. Hun Berry shows ventilating-fans and a lid-back engine. The Jones Manufacturing Co. show the Gem water-filter for household purposes. Alfred J. Gilderson also shows water-filters attached to faucets. The Seibert Cylinder Oil-Cup Co. show their steam-engine lubricators. The Portland Stone-ware Co., terra-cotta ware drain-pipe, etc. The Ormsby Sash Balance Co., sash-balances. The New England Terra-Cotta Lumber Co. show their terra-cotta lumber for fire-proofing buildings. Samuel Cabot, Boston, creosote wood-preserving stains, has a 6x8 model of a \$15,000 house, Queen Anne style, shingled all over, giving an excellent idea of the effect of his stains. The New England Heat-Regulator Co. show the Butz electric heat-regulator. Tingley & Dorrance, Providence, R. I., tile and brass registers, brass-work, etc. Reading, Baird & Co., Boston, show stained glass. Errico & Co., terra-cotta and majolica works of art, bronzes, etc. The Lowe Tile and Metal Manufacturing Co., of Chelsea, have a large display of tiles in every shape. They also have a large exhibit of their specialties in artistic combinations in tiles and metals. Amongst them are tile-lamps, tea-bells, table-

stands, inkstands, candle-sticks, twine-reels, letter-files, ash-trays, etc.

Charles W. Trainer & Co., Boston, show the various products of the H. W. Johns Manufacturing Co., consisting of stove lining, furnace cement, corded sheathing, asbestos steam packing, pipe and boiler coverings, etc. The Chalmers-Spence Co., of New York, show samples of their asbestos pipe covering. The Crosby Automatic Signal Co., of Providence, R. I., have on view their automatic fog signals. The Dana Wind-Engine Co., of Fair Haven, Mass., has one of their 16-foot centrifugal governor wind-engines placed on the roof of the exhibition building, connected by a line of shafting with shaftings and pulleys, for running a circular saw and grinding mill. The Simonds Manufacturing Co., of New York, have the wing disc fan or exhauster and the wing-fan-ventilator.

The Soule Photograph Co. and L. Prang & Co. have on view a fine exhibit of their respective productions.

The stove, range, and furnace houses are well represented. We notice a good display from the Smith and Anthony Stove Co., David W. Cushing, the Magee Furnace Co., the Weir Stove Co., the Ridgeway Furnace and Stove Co., the Taunton Iron-Works, the Barstow Stove Co., and S. M. Howes & Co.

The American Conduit and Construction Co. exhibit carbonized stone conduits for electric wires.

The Perth Amboy Terra-Cotta Co. have a fine exhibit of architectural terra-cotta, including some specimens of interior work and Pompeian terra-cotta. The Boston Architectural Terra-Cotta Works, H. A. Lewis, proprietor, has recently amalgamated with the Perth Amboy Co., and this exhibit is the combined effort of the two concerns. The commission for the city of Boston for testing the merits of the several water-meters are continuing their labors at the Exhibition Building; having occupied the space for some time, and not having completed their work, their apparatus has been entered as an exhibit.

ARCHITECTURAL COMPETITIONS.

MINNEAPOLIS.—The Court House and City Hall Commission have appropriated \$4,000 for competitive plans for new court house and city hall. Most meritorious plan, \$1,500; second, \$1,000; third, \$600; fourth, \$500; fifth, \$400. These plans to remain the property of the Board. If any one of the competitors is selected the money given for his plans shall be counted in his competition. The official announcement may be found in our advertising columns and the instructions may be secured at the office of THE ENGINEERING AND BUILDING RECORD.

MISCELLANEOUS.

MILWAUKEE.—The work of the City Engineer on the proposed flushing-tunnel has been stopped, as the Chicago and North-western Railway refuse to grant the right of way under their tracks unless the city authorities permit the railroad company to build a solid sea wall from a point on the Lake opposite the foot of Mason Street to the lighthouse pier, to be not less than 200 feet from the shore. The new breakwater will be twenty feet wide and fifteen feet above the water-level, and will have a railing on either side so that it can be used as a promenade. A foot-bridge will be built connecting the end of the breakwater to Juneau Park.

MILWAUKEE.—The statue of Leif Erickson is on its way here, and the contract for erecting the pedestal has been let to Cook & Hyde. The pedestal weighs 41,740 pounds, and the statue weighs 1,200 pounds. The entire height of the statue and pedestal will be 18 feet. M. H. Mosman is the founder of the statue.

POMONA, CAL.—The San Antonio and Holt Avenue Railroad Company has filed articles of incorporation to construct a street railroad in Pomona, from the intersection of Second and Elizabeth Streets to the San Bernardino Road. Capital stock, \$25,000.

ELIZABETH, PA.—Editor Wiley and Dr. Sheaffer represent the stockholders of the company organized to build a bridge across the Monongahela River at Elizabeth.

DENVER, COL.—The *Tribune* is strongly urging the matter of paving the streets of the city.

MILWAUKEE, WIS.—The Milwaukee and Northern Railroad will be extended to Rockland, a distance of sixty miles. The line has already been surveyed.

SAN DIEGO, CAL.—The application of Milton Sauter to build a wharf on D Street has been granted. The wharf is to be 3,700 feet long; estimated cost, \$50,000.

SAN DIEGO, CAL.—It is reported that owing to the immense amount of building of all kinds that is going on in this city and vicinity, the municipal authorities are experiencing difficulty in securing contractors to perform street work. It is stated that there are some 14 streets in the city which have been ordered graded and advertisements for proposals have been issued without any resulting bids.

NEW INCORPORATIONS.

MILWAUKEE.—Incorporated is the Home Building and Loan Association of Milwaukee. C. A. Chapin, E. G. Timme, and others are incorporators. The capital stock is \$500,000.

PORTLAND, ME.—Organized is the New England Liquid Fuel Company at Portland, with a capital stock of \$15,000. The stockholders are Oliver P. Prall, West Somerville, Mass.; John Gray and others, Arlington, Mass.

BROWNSFIELD, PA.—The Redstone Water Company has been incorporated; capital stock, \$6,000. W. C. Magee, J. M. Schoonmaker, Pressley H. Moore, and L. H. Schoonmaker, incorporators.

THE Pacific Sewerage Company; incorporators, A. M. Jordan, Atlantic City; W. S. Snyder, and A. C. Cramer, of Philadelphia. The Red Lion Town Site Company; capital stock, \$25,000; incorporators, F. O. Bell, S. M. Martin, John Zigler, and E. O. Wight. The Teocalli Mining Company; capital stock, \$100,000; incorporators, Edward Royston, of Pueblo, and the following citizens of Marysville, Mo.: F. M. Cooper, S. W. Briggs, Frank Baummann, J. K. Whidbee, O. P. Torrance, and E. A. Vinsonhaler.

NEWARK, N. J.—The United States Traction Company has filed articles of incorporation. The capital stock is \$1,000,000 and the incorporators are Andros B. Stone and Eugene M. Cole, of New York, and T. Walter Griffith, of Newark. The object is to build street cable railroads and construct elevated and underground railroads.

North-Western Gas-Saving Co., of Chicago; capital stock, \$50,000; incorporators, Charles C. Rice, S. August Gould, L. R. Vastine. The Niagara Falls Hydraulic Power and Motor Company, at Chicago; capital stock, \$15,000,000; incorporators, M. Morgner, E. C. Phillips, and E. B. Morgner. The Phillips Economical Cable-Grip Construction Company, capital stock, \$5,000,000; incorporators, R. Morgner, E. C. Phillips, and E. B. Morgner. Commonwealth Gas Co., at Chicago; capital stock, \$500,000; the incorporators are J. G. Aldrich, B. F. Cummings, and Edward H. Turner.

The Chicago Western Elevated Railway Company; capital stock, \$20,000,000; for the construction and operation of an elevated railroad from a point on Michigan Avenue, between South Water Street and Monroe, running west to the west line of Cook County; incorporators, James Felch, George S. Calkins, and Ezra L. Brainerd. The Chicago Rapid Transit Company; capital stock, \$1,500,000; to construct and operate elevated railways within and without the city of Chicago and its suburbs; incorporators, George C. Buell, Edward S. Richards, and James C. Beeks. The Edison Illuminating Company, of Monmouth; capital stock, \$10,000; incorporators, H. H. Pattee, H. A. Scott, and W. B. Smith.

THE New York Electric Construction Company; capital, \$50,000.

THE Young-Brennan Crusher Company, of New York; capital, \$200,000.

TUCSON, ARIZ.—Articles of incorporation have been filed by the Canoya Canal Company, with a capital of \$500,000. The object is to take out a grand irrigating canal to reclaim land in Santa Cruz valley, between Tucson and Calabasas. One hundred thousand acres will be reclaimed.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

For works for which proposals are requested see also the "Proposal Column," pages 697-700-703-704.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE ENGINEERING & BUILDING RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

WATER. SEWERAGE. ETC.

ROCHESTER, PA.—John M. Buchanan, of Beaver; Dr. H. S. McConnell, of New Brighton; A. W. McCoy, of this place; Ellis Morrison, and E. A. Phillips, of New Castle, compose the Rochester Water Pumping Company, which proposes to erect works here within the coming year if the prospects will warrant it. Already the Town Council has contracted for sixty plugs at a cost of \$2,750 per year, and a tour of the various factories, etc., is being made for the purpose of ascertaining whether \$6,500 worth of contracts per year can be made. The entire plant as at present planned will cost over \$130,000. Locations for the pump-station, as well as the reservoir, have already been chosen, and will be purchased within the next week or two.

ALBERT LEA, MINN.—This place is to have a system of water-works. Three or four miles of mains will be laid, and about \$30,000 will be expended. For particulars address C. H. Farnsworth, at this place.

SULLIVAN, ILL.—At a recent meeting of the City Council it was decided to expend \$25,000 for new water-works. The wells of the old works will be used.

BRISTOL, TENN.—The water-works question is being agitated here.

BATH, L. I.—A sewerage system to cost \$100,000 is in contemplation here.

BATON ROUGE, LA.—The City Council has contracted with Mr. Wood, of Dubuque, Iowa, for the building of a system of water-works in this city, agreeing to pay \$4,500 per year for seventy-five hydrants. Work is to begin soon and be completed within six months.

WINDOM, KAN.—Our correspondent writes: "The Mayor and City Council have passed an ordinance submitting to the vote of the citizens of the city of Windom a proposition to vote bonds to the amount of \$8,000 for the purpose of building and operating a system of water-works, the said election to take place November 15."

CHARLESTON, S. C.—Our correspondent writes: "The city of Charleston, S. C., has ten artesian wells, about 2,000 feet deep, yielding about 700,000 gallons daily. These wells flow into a reservoir of 3,000,000 gallons capacity, situated in the heart of the city, from whence the water is pumped into a stand pipe ninety feet high and eighteen feet in diameter. A third well is now being bored upwards of a mile from the present reservoir and pumping station, and it is proposed to construct at that point a reservoir of 5,000,000 gallons capacity, into which the water from the new well will flow, and from which it will be conveyed by gravity through cast-iron pipes of ten inches diameter, to the central reservoir whenever needed. This third well is expected to be of larger size than the others, and it is hoped will yield over a million gallons daily."

CAZENOVIA, N. Y.—Our correspondent writes: "There has been no steps taken looking to the establishing of water-works, further than that parties have been here looking the thing over, but there has been no movement in that direction by the people."

LAKE FOREST, ILL.—Our correspondent writes: "No steps have been taken yet and nothing will be done before spring."

SEBASTOPOL, CAL.—Our correspondent writes: "This is not an incorporated city and there are no water-works, only for my private use, of engine for pumping tanks of 21,000 gallons."

ST. PAUL, MINN.—The water board has let the contract for the high-service distributing-reservoir, which is to be begun April 15, next year, and completed October 12: McArthur Bros. bid \$97,681.45; J. D. Moran, \$114,006.50; the Fruin-Bambroch Construction Company, of St. Louis, \$115,526.05, and J. J. Palmer, of Minneapolis, \$119,102.39. The contract was awarded to McArthur Bros. The work will be done under the supervision of H. H. Harrison, of Stillwater, engineer of the board, and Professor J. T. Fanning, of Minneapolis, Consulting Engineer. In the bid of McArthur Bros. forty tons of pipes and special castings will be used, and twelve tons of gate-valves and curbs.

WESTERVILLE, O.—The question of building water-works is being agitated here.

MISSOURI VALLEY, IA.—Our correspondent writes: "The City Council ordered an unofficial vote at the State election on the question of bonding the city in the sum of \$25,000 to erect water-works, merely to get the expression of the people. The question carried by a large majority in favor of bonds and the Council will probably vote bonds some time before spring and begin the erection of water-works as soon as the season opens up."

SPARTANBURG, S. C.—Our correspondent writes: "Contract for water-works has been let to Moffit, Hodgkins & Clark, of Watertown, N. Y., who will go to work very soon."

ST. LOUIS, MO.—An extension to the water-works, to cost \$700,000, is to be made. For particulars address Comptroller Campbell, this city.

LAKE LINDEN, MICH.—This place will be bonded for \$10,000 to put in a water-works plant.

JERSEY CITY, N. J.—The Board of Public Works has awarded the contract for covering the water-main, which is composed of cement, to Thomas Cavanaugh, the lowest bidder.

COLUMBIA, S. C.—Our correspondent writes: "We have had plans drawn for new reservoir and have solicited bids from all of the best pump-makers that we know of in the country, and as soon as replies are received will order the pumps at once. The committee have not yet decided whether they will purchase a one or one and a half million gallons capacity pump in twelve hours. The work on reservoir and purchasing pump will be pushed with all possible speed consistent with good work, and purchase of a No. 1 pump."

COLUMBUS, O.—Our correspondent writes: "The laying of additional pipe-lines has been postponed for the present."

EAST ORANGE, N. J.—Our correspondent writes: "No steps have been taken to extend the sewerage system beyond the original plans in the township of East Orange, which is now in progress of construction."

WALTHAM, MASS.—Our correspondent writes: "The sum of \$600 has been appropriated for preparing plans for a sewerage system, and the Mayor has been requested to petition the next Legislature for a special act authorizing the city to borrow money to construct drains and sewers."

HAVERHILL, MASS.—Address Joseph H. Sheldon, Mayor, for proposals for furnishing materials and constructing marginal sewers, until November 25.

VICKSBURG, MISS.—Our correspondent writes: "This city has contracted with the firm of Samuel R. Bullock & Co., of New York, for a system of water-works, which are now in the course of construction and will be completed in the course of three or four months."

ROME, GA.—It is proposed to form a \$100,000 stock company to buy the Rome Water-Works. J. W. Rounsaville can give information.

PINE BLUFF, ARK.—The Pine Bluff Water-Power Company has been incorporated; capital stock, \$150,000.

NEWPORT, R. I.—Our correspondent writes: "The only work contemplated at present is building a storm overflow by hired labor."

TECUMSEH, MICH., is to have a water-works system. Address F. B. Wood.

ALFRED CENTRE, N. Y.—A system of water-works will be constructed here.

BELLEVILLE, ILL.—Our correspondent says, in reference to an item published recently, saying that water-works were to be established here: "We have water-works established 3 years ago."

MT. VERNON, N. Y.—Our correspondent writes: "The Mt. Vernon village officials are constructing a new sewer. Mr. Otto Hirfeland, Mt. Vernon, N. Y., is Clerk to the Commissioners having the matter in hand."

COLUMBUS, GA.—Our correspondent writes: "This city has been building sewers of various lengths in those portions of the city as were most needing them, generally by contract, and has expended for same about \$17,000 this year. I presume the same plan will be pursued next year. A definite and enlarged plan, I think, would be desirable."

PITTSBURG, PA.—It was evidently an error in reporting water-works at North Versailles last week. Our correspondent writes: "Referring to your inquiry above, state that I am not aware of any such improvement being made or contemplated at North Versailles, this county, as it is a small country village and cannot support a water-works of any kind."

MILWAUKEE.—A large sewer will be built along Chestnut Street, extending through the Highland Home property, recently purchased by Harrison & Green.

WAUPUN, WIS.—Boring in the public artesian well has ceased at a depth of nearly 800 feet. The Common Council directed the contractor to pipe and pack the well, with the hope of getting a flow of water. If, after this job is done, the well will not flow at the surface, it will be supplied with a pump.

BRIDGEPORT, CONN.—Negotiations are in progress between prominent stockholders of both the water companies of this city which will undoubtedly result in a short time in the combination of the interests of the two for business purposes under one control, and the advantages of the new water-supply from Mill River will be secured to Bridgeport and West Stratford without putting down another set of pipes save wherever streets are not already piped or need a larger or better supply.

WINSTON, N. C., November 14.—Our correspondent writes: "The question of sewerage is lying dormant now, but I think it will be put through during 1888."

SALISBURY, MD.—Our correspondent writes that there are no new developments concerning the water-works project.

WHITESTONE, N. Y.—Our correspondent writes in relation to the water-works project at this place: "The Trustees have in view a negotiation with the village of College Point for a water-supply. No decided steps have been taken other than requesting their President to ascertain what can be done in the matter."

CLEBURNE, TEXAS.—Our correspondent writes concerning the project to increase the water-supply: "The city has contracted for an artesian well, which is now bored about 800 feet. Water is within 120 feet of surface, and they expect to continue boring until a flowing well is secured. There is a determination on the part of the city to secure an abundant supply at any cost."

BROOKLYN, N. Y.—Austin Corbin, President of the Long Island Railroad, has given the city the privilege of constructing the conduit through lands owned by his company in Merrick, Redwood, and South Oyster Bay, through which places the conduit will be built instead of over the route originally intended, thereby removing the obstacle in the way of the proposed extension of the Brooklyn Water-Works. It is now thought that the dead-lock in regard to the extension of the water-works will soon be broken.

GEORGETOWN, KY.—Proposals wanted for a system of water-works. Until November 21. Address Moore & Thompson, this city.

SAN BERNARDINO, CAL.—The West Highlands Water Co. has been incorporated; capital stock, \$90,000. Seth Marshall, A. E. Sterling and others, incorporators.

SAN FRANCISCO, CAL.—The Laguna Blanca Water Co. has been incorporated; capital stock, \$1,000,000. Timothy Hopkins and S. T. Gage, of Oakland, and others, incorporators.

HERMOSA, CAL.—The Hermosa Water Co. has been incorporated; capital stock, \$192,000. Reidorf Almind, H. W. Lawrence and others, incorporators.

PLYMOUTH, IND.—Our correspondent says: "Have not decided as to the system but think we shall have the 'direct system.' We cannot bond the city to exceed \$160,000. At present I can give no further information."

WOODSTOCK, VT.—The water-works are about completed. A 15,000,000 gallon reservoir has been constructed and 7 miles of pipe have been put in. The work is being done by T. William Harris & Co., of New York.

GRAFTON, W. VA.—Water-works will be erected here. Henry S. Wilson can give information.

MYSTIC, CONN.—Our correspondent writes: "Last winter there was a charter granted by the Legislature for water works for Mystic and Stonington, and I don't know what they will do; it will depend on the Railroad Company at Stonington."

BATH, N. Y.—Our correspondent writes: "There has been nothing done in the sewerage matter as yet. We have only called the people together to get their views as to the manner, and get some idea as to the cost."

GENESEO, ILL.—Our correspondent writes: "Our water-works, composed of steam-engines, apparatus, water-mains, etc., up to last spring have cost the city about \$25,000, to which we have added this season an artesian well 2,250 feet deep, giving us a flow of 200 gallons of beautiful mineral water per minute at a cost of \$6,000. We are now extending our water-mains 13,500 feet, which will be completed in ten days, at a cost of \$11,000 or \$12,000."

KEOKUK, IA.—Our correspondent writes: "The question of establishing a general sewerage system has been under discussion several times by our City Council, but has not assumed any shape. Our city needs a perfect system, and must, of necessity, adapt something very soon. About 2,000 or 3,000 feet of main sewer will be constructed this winter or next year, without doubt."

STAUNTON, ILL.—Our correspondent writes: "An election has been called for December 15 to see whether the people will authorize the Trustees to issue bonds for the purpose of building water-works."

PRINCETON, ILL.—Our correspondent writes: "Water-works are under contemplation on a small scale; \$5,000 has been voted and appropriated for an artesian well, and the Mayor has advertised for bids for sinking the same."

JAMESTOWN, N. Y.—Our correspondent writes: "The water company, of this city, has driven four 8-inch artesian wells at Levant, about four miles from this city, which are now flowing. The company proposes to bring the water from those wells for city use."

HENDERSONVILLE, N. C.—Our correspondent says: "No sewerage system has been inaugurated, but one may succeed the completion of the water-works system."

TUSCUMBIA, A. I. A.—Our correspondent writes in regard to the water-works of East Sheffield and Tuscumbia: "All the stock has been taken in the above-styled company but no further progress as yet."

READING, PA.—Our correspondent writes: "The Water Board will recommend to Councils that action be taken looking to an increase of the supply during next year."

MERRIAM, MINN.—Water-works are wanted here.

HUMMELSTOWN, PA.—Contracts for the water-works have been given out footing up \$40,000. Schaeffer, Mukel & Co., of Fleetwood, will put in the machinery at a cost of \$9,000. Raymond & Campbell, of Middletown, will furnish and put in the conduit and standpipes for \$27,000. Other contracts, cost of ground, etc., run the total up to more than \$45,000.

BOUND BROOK, N. J.—Address the Commissioners in regard to water-works system to be constructed here.

LOUISVILLE, KY.—The Louisville Water-Works Co. propose extending their water-works system.

PIPSTONE, MINN.—Our correspondent writes: "This place voted \$20,000 for water-works November 14."

WINCHESTER, KY.—Our correspondent writes: "The Council has appointed a committee, Messrs. William A. Attersall and Joseph H. Frazer, who have visited Lexington, Frankfort and Louisville to investigate water-works systems in view of establishing a plant here, but circumstances have been such that they have not been able to report. Nothing will be done until they report."

HOBOKEN, N. J.—Our correspondent writes: "The Jamestown system of water-works is recommended for this city."

MILWAUKEE, WIS.—An engineer for the county water-works is wanted. The position is a new one and will be made effective. The salary will be \$1,500 per annum.

BRIDGES.

GREEN BAY, WIS.—Our correspondent writes: "No steps taken yet toward the construction of a draw on Walnut Street bridge. Before any is taken by the authorities the matter will have to be voted on by the voters of the city, and in case the vote is in favor of the improvement the city will have to issue bonds to pay for it."

COLUMBUS, NEB.—Plans for the bridge across the Loup Fork River have been examined by the township and city authorities of Columbus, and accepted the plan of the Campbell Bridge Company, of Council Bluffs, Iowa, at an estimated cost of \$37,000.

ROME, GEO.—The contract for the bridge over the Postanula has been awarded to the Penn Bridge Co. for \$13,457, the company to take down the old bridge and place it on the river bank. The bridge will be 297 feet long, with the draw 197 feet long; the other 100 feet, will have a roadway twenty feet wide. The piers will be all stone.

NEW GLASGOW, N. S.—The people are agitating the question of erecting a bridge over the East River to connect with Stellarton.

TROY, N. Y.—The directors of the Troy Union Railroad Co. have awarded the contract for constructing a new bridge at Pine Street to Van Zile & Co., of Albany, N. Y.

BEVERLY, MASS.—Our correspondent writes that the County Commissioners have taken no action toward the erection of a bridge over the railroad from Rantoul to River Streets.

SEYMOUR, IND.—The County Commissioners will build a bridge here.

KANSAS CITY, MO.—It is reported that the County Court has ordered four new bridges to be constructed across Brush Creek, O. K. Creek, and the Little Blue River; all to be of iron, the longest one to be 300x60 feet in size, and two of them will be built so as to allow cable cars to pass over them.

NORTH PLATTE, NEB.—It is reported that North Platte and Lincoln County will vote on bonding the county for \$60,000 to build five bridges across the Platte River.

LA CAMAS, WASH. T.—A bridge is to be built across the Columbia River from the Oregon side to La Camas, Washington Territory.

MENOMINEE, MICH.—Address the County Commissioners in regard to a bridge, to cost \$70,000, to be constructed here.

CHICAGO, ILL.—A. Gottlieb & Co. have been awarded the contract for building the Jackson Street viaduct at \$89,840.

GAS AND ELECTRIC LIGHTING.

INDIANAPOLIS, IND.—This city is about to buy \$100,000 worth of wrought-iron pipe to conduct natural gas here from wells twenty miles away.

FORT EDWARD, N. Y.—This place is to be lighted with electricity by a company of local capitalists.

UTICA, N. Y.—The New York Electric Construction Co., of New York City, has been awarded the contract to establish a plant here.

ALBANY, N. Y.—The city has contracted with the Westinghouse Electrical Co. to construct a plant for 2,600 lights.

COLUMBUS, O.—A contract has been made with the Westinghouse Electrical Co. to erect a plant for 2,600 lights.

RED BANK, N. J.—This place will be lighted by electricity. A \$10,000 plant will be established and a franchise will be granted as soon as the company is fully organized.

TAUNTON, MASS.—The Frank S. Marr Construction Company is preparing to put 1,250 incandescent lamps into the Hoosac Tunnel. The Westinghouse alternating system will be used.

KNOXVILLE, TENN.—The report of the Board of Public Works favoring electric light to gas has been received and accepted by the Board of Aldermen.

CARLISLE, PA.—An electric light and steam heating company has been organized and is asking permission of councils to erect the necessary poles and plant.

VICTORIA, TEX.—There are prospects of an electric-light plant being erected.

ITHACA, MICH.—An Edison electric-light company has been organized here.

HUTCHINSON, KAN.—An electric-light plant will be erected here at once.

BRISTOL, TENN.—The Thomson-Houston Electric Light Company have a franchise to erect a plant here. Work will be begun at once.

KEOKUK, IOWA.—The people are agitating a cheaper system of electric lights.

TALLAHASSEE, FLA.—The City Council has contracted with the Tallahassee Brush Electric Light Company to light the streets of Tallahassee for the term of five years. The hotels and stores will also use the light, and it will be used in the Capitol during the session of the Legislature.

NEW CORPORATIONS.—The Lock Haven Electric Light Co., of Lock Haven, Pa., has been incorporated. Capital stock, \$20,000. Samuel Christ, T. C. Kintzing, and others, incorporators.—The Lamar Electric Light and Gas Co., of Lamar, Col., has been incorporated. Capital stock, \$50,000. T. J. Mathews, O. G. Hess, and others, incorporators.—The Staten Island Electric Co., of New Brighton, S. I., has been incorporated. Capital stock, \$10,000. Fred B. Hawley, Edwin T. Copeland, and others, incorporators.—The New York Electric Construction Co., City, has been incorporated. Capital stock, \$50,000. Andrew L. Souard, J. H. Hapgood, and others, incorporators.—The Martinez Gas and Electric Light Co., of Martinez, Cal., has been incorporated. Capital stock, \$50,000. J. Strenzel, D. Thomas, and others, incorporators.—The Thomaston Electric Light Co., of Thomaston, Conn., has been incorporated. Capital stock, \$20,000. Aaron Thomas, B. W. Pease, and others, incorporators.—The Schuyler Electric Co., of Middletown, Conn., has been incorporated. Capital stock, \$250,000. Seth H. Butler, John N. Camp, and others, incorporators.—The Anniston Gas-Light Co., of Anniston, Ala., has been incorporated, with W. G. Ledbetter as President.—The Lamar, Col., Electric and Gas Light Co., with \$50,000 capital, has been incorporated. O. G. Hess, W. W. London, and others are the incorporators.

GREENVILLE, S. C.—Julius H. Howard has made a proposition to light the city with electric lights.

CHADRON, NEB.—It is probable that a system of electric lights will be wanted here shortly.

TROY, N. Y.—The contract with the Edison Electric-Light Company for lighting the depot of the Troy Union Railroad Co. has been ratified. The company agrees to have the electric-light in operation December 15.

FORT EDWARD, N. Y.—Our correspondent writes: "Electric-Light Company just formed; Westinghouse system in operation in Fourth to Sixth Streets."

NEWPORT, O.—The Kentucky Electric-Light Co. has been refused a franchise to erect a plant here.

HYDE PARK, ILL.—An ordinance has been passed giving the Economic Electric-Light and Gas Co. permission to locate and operate a system of gas and electric-light at the rate of \$1.25 per thousand feet gas, electric arc-lights at sixty cents per night, and ten cents per night for incandescent light.

RAILROADS, CANALS, ETC.

WHEELING, W. VA.—The contract to build the Wheeling Electrical Railroad has been awarded to John Robrecht.

MADISON, WIS.—The Madison City Railway Company has filed articles of incorporation. The capital stock is \$30,000. The incorporators are E. W. Keyes, Joseph S. Keyes, and George Wolf.

BETHELEHEM, PA.—The Plymouth Passenger Railway Co. has been incorporated with a capital of \$12,000.

INDIANAPOLIS, IND.—The Central Indiana Railroad Company has been incorporated. It proposes to build a line from Fort Wayne to Terre Haute, a distance of 200 miles. The capital stock is given at \$100,000, of which Lewis J. Highland has subscribed 986 shares.

ROME, GA.—Address J. W. English, President Chattanooga Brick Co., for particulars concerning proposals wanted for grading, masonry, trestling, and all other parts of railroad construction on the Chattanooga, Rome and Columbus Railroad.

MADISON, WIS.—The Portage and South-Western Railroad has been incorporated. It proposes to build a road from Portage City to a point on the boundary between Wisconsin and Illinois, together with a branch from some point on the line in Dane County to Madison. The total distance is 135 miles. The capital stock is \$3,750,000. The incorporators and first board of directors are Bluford Wilson, Frank H. Jones, Samuel T. Dresser, Timothy McGrath, and Henry A. Stevens, all of Springfield, Ill.

STUEBENVILLE, O.—An electric railway is to be built here. T. William Harris, of 2 Nassau Street, New York, is the consulting engineer, and Wilbur F. Goodrich, M. A. S. C. E., is to make the surveys.

WILMINGTON, DEL.—This city has closed a contract with T. William Harris & Co., of New York, for putting poles, wires, etc., for an electric railway.

BIDS OPENED.

ST. PAUL, MINN.—Bids have been opened by the Board of Public Works, as follows: Feronia Avenue, from Prior Avenue to Fairview Avenue: Michael Lux and Robert Spangenberg, \$1,166; Michael F. Duggan, \$1,390; Carl Bahr and F. Kuhr, \$1,095; William A. Davern, \$1,235. Awarded to Bahr and Kuhr.

Mackubin Street, from Charles Street to Minnehaha Street: Michael Lux and Robert Spangenberg, \$3,490; William A. Davern, \$2,725; William P. Murphy, \$2,998.70; J. W. Maloney, \$2,287; G. Gerlich, \$2,150. Awarded to Gerlich.

Sewer on Mackubin Street, from Rondo Street to Carroll Street, together with the necessary catch-basins and manholes: Patrick Doherty, \$593; William Stockton and John Lindquist, \$799. Awarded to Doherty.

Sewer on Iglehart Street, from Farrington Avenue to Western Avenue, and from Mackubin Street to Dale Street, and on Dale Street from Iglehart Street to Marshall Avenue, together with the necessary catch-basins and manholes: Patrick Doherty, \$10,098; William Stockton and John Lindquist, \$8,900. The last-named bids were rejected.

The contract for paving Selby Avenue was awarded to James Forestal, at \$34,700.

CINCINNATI, O.—The contract for building the armory in this city has been awarded to James Griffiths' Sons at their bid of \$95,284.

NEW YORK CITY.—The Aqueduct Commissioners, November 16, opened the following bids for the construction of gate-house chambers and blow-offs at Pocantico, in Section 4, and at South Yonkers, in Section 9, of the aqueduct work: Section 4—Brown, Howard & Co., \$24,717.50; Thomas Dobbin, \$13,912.50, and John Peirce, \$22,410.50. Section 9—O'Brien & Clark, \$20,935; John Peirce, \$22,160.50, and Thomas Dobbin, \$22,836.20. The bids were referred to the Chief Engineer to be tabulated.

ST. LOUIS, MO.—The Board of Public Improvements received bids yesterday for the improvement of parts of Grand Avenue and Broadway. The bids for the reconstruction with granite of Broadway from Franklin Avenue to Biddle Street were: Allen & Vieths, \$21,273; P. W. Schneider, \$22,314; G. Eyer-mann, \$22,482. For the section of Broadway from Biddle to O'Fallon Street, Fred Skrainka bid \$9,868; P. W. Schneider, \$10,403; Allen & Vieths, \$9,916; G. Eyer-mann, \$10,431. The bids for the reconstruction of Grand Avenue from Laclede Avenue to the centre line of Morgan Street with pine wood blocks treated with chloride of zinc were: George Schmalz, \$58,764; Allen & Vieths, \$59,068; Fred Skrainka, \$61,060; J. Michel, \$57,665. For like reconstruction of that part of Grand Avenue between Morgan Street and Easton Avenue, Fred Skrainka bid, \$49,135; J. Michel, \$44,403; Allen & Vieths, \$47,534; George Schmalz, \$48,062. The bids for the reconstruction of Broadway from Mullanphy Street to Hempstead Street were Fred Skrainka, \$30,356; Allen & Vieths, \$29,922; G. Eyer-mann, \$31,473. Fred Skrainka bid \$18,539 for the reconstruction of Broadway, from Hempstead to Chambers Street; Allen & Vieths, \$18,281; G. Eyer-mann, \$18,232. For that section of Broadway between Chambers and North Market Fred Skrainka bid \$22,124; Allen & Vieths, \$22,229, and G. Eyer-mann, \$23,264. Broadway from North Market Street to Louis Avenue, Allen & Vieths, \$22,231; G. Eyer-mann, \$23,256. The contracts will be awarded to-day.

BOSTON, MASS.—Synopsis of bids for roofing and copper for the Chestnut Hill pumping-station, received by the Boston Water Board November 14:

Copper—E. B. Badger & Sons, \$1,695; Edward Marley & Bros., \$1,393; E. Van Noorden, \$1,995; F. H. Holton & Co., \$2,700; Awarded to Marley & Bros.

Roofing—C. S. Parker & Son, \$4,675; J. Hanigan & Son, \$5,100; George Martis, \$4,274; W. J. Maynard, \$4,525; John Farquhar & Sons, \$4,000; E. Marley & Bros., \$4,300. Awarded to Farquhar & Sons.

CHATTANOOGA, TENN.—The contract to erect two iron bridges has been awarded to the Union Iron Co. at \$2,100.

LANCASTER, PA.—The Committee on Sewerage, Drainage and Water-Works Improvement met on Friday evening and opened proposals for excavating and building the wall at the run on the new water-works grounds, as follows: John Hook, \$6.50 a perch, for wall and coping stone. J. F. Stauffer, \$6.50 per perch and 25c. per cubic yard for excavating. Kitch & Smith, \$4.90 per perch including coping of Port Deposit granite six inches thick and two feet two inches wide, at 30c. per cubic yard for excavating. Licht & Kreckel, for the entire work, \$2,750. Awarded to Kitch & Smith, as the lowest bidders.

CHATTANOOGA, TENN.—The contract to build several sewers, costing \$8,000, has been awarded to Messrs. Cleary & Davidson, of Chicago.

GOVERNMENT WORK.

SYNOPSIS of bids for plumbing and gas-piping in Court-house, etc., at Shreveport, La., opened November 15:

Mannion & Co., \$2,575; Utz & Smith, \$4,420.90

ST. LOUIS, MO.—Synopsis of bids for iron columns, etc., and girders and floor beams for Custom House, opened November 14 by the Supervising Architect of the Treasury Department: Haugh, Ketcham & Co. Iron-Works Co., \$23,645; Dearborn Foundry Co., \$25,910; Christopher & Simpson, \$24,417; South Halstead Street Iron-Works, Chicago, Ill., \$25,799; The McHenry Judge Arch. Iron Co., \$23,857; Sweeney & Bro., \$20,700; Scherpe & Koken, \$26,900; Willis Bros., \$26,500; McCarthy & Bro., \$48,480.

WACO, TEX.—Synopsis of bids for approaches to public building, opened November 15 by the Supervising Architect of the Treasury Department: McCarthy & Baldwin, \$8,969; John Boode, \$2,440; Dumesniel & Bro., \$7,625.

TYLER, TEX.—Synopsis of bids for approaches to public building opened November 14 by the Supervising Architect of the Treasury Department:

Moore & Parkhurst, \$1,498; John Myers & Son, \$7,500; Dumesniel & Bro., \$6,259; McCarthy & Baldwin, \$5,865.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1887, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

SIX YEARS' EXPERIENCE WITH THE MEMPHIS SEWERS.

ENGINEERS and municipal authorities will be interested in the report of Mr. Rudolph Hering, made to THE ENGINEERING AND BUILDING RECORD and published on another page, of an inspection made by him of the Memphis sewerage system, on the occasion of a recent visit to that city. We requested Mr. Hering to report especially upon the question of stoppages in pipe-sewers and the experience resulting from the attempt to dispense with manholes. The older readers of this journal will recall the controversy carried on in its columns during the years 1880 and 1881 regarding the importance of providing any sewerage system with manholes. This was started by a review we published of alternate plans proposed for the city of Newport, R. I., in our issue of December 1, 1880. In that review we commended certain features of the plan recommended by Colonel Waring, but among the objections we made to it was one condemning the proposition to omit manholes. In discussing this plan and alluding to the separate system, by which we meant the system as then understood by engineers, we stated that for certain localities it had many advocates, mentioning, among others, Sir Robert Rawlinson, Chief Engineer of the Local Government Board of Great Britain. This called out a letter from Sir Robert Rawlinson, which was published in our issue of March 15, 1881, he supposing we intended to imply that he endorsed what was called the Waring system, which, of course, included the details of construction adopted by Colonel Waring at Memphis. In this letter Mr. Rawlinson stated:

"I have written quite enough on sewerage and draining to refute the statement that I approve of the mode adopted by Colonel Waring all round, and any person may learn this by looking at my published 'Suggestions for Main Sewering' (revised to 1878).

"In these suggestions it will be seen that I insist upon right lines and true gradient, with manholes or lamp-holes at each change of line or gradient, special arrangements for steep gradients, and abundant provision for sewer and drain flushing and ventilation. In so far as Colonel Waring departs from these suggestions I entirely differ from him, and if he persists in disregarding these precautionary works against failure, without being either a wizard or a prophet, I predict failure; because the sewers when closed in will be beyond inspection without breaking down to them, and this operation must be blind, haphazard work.

"I know quite well that to work under the rules may cost more money in the outset, but will tend to great saving in the long run."

This was replied to by Colonel Waring April 1, 1881, in which he defined the essentials and non-essentials of a sewer system as follows:

ESSENTIALS.—"Exclusion of all storm water, absolute tightness, absolute cleanliness, perfect precision of gradient, regular, automatic, efficient flushing, complete ventilation, and perfect construction."

NON-ESSENTIALS.—"Lateral alignment; and facility of inspection."

On April 15, 1881, appeared a communication from Edward S. Philbrick, C. E., of Boston, in which he defended the use of manholes, and stated that—

"In omitting them Colonel Waring launched out upon new and unbeaten paths, pursuing methods which had been discarded as bad ones by nearly all engineers who had had much experience in the construction and main-

tenance of city sewers during the past generation, both in this country and in England."

This discussion on the need of manholes was continued during a portion of the year 1881, Messrs. Rawlinson, Philbrick, and G. K. Radford agreeing with the position taken by this journal in opposition to that assumed and defended by Colonel Waring. In our issue of March 20, 1884, we published a statement prepared for us by Mr. Anthony Ross, Superintendent of Sewers, giving cost of the Memphis system for the years 1882 and 1883. In 1882 fifty obstructions were reported, with a cost for removal of \$657.15. In 1883 seventy-three obstructions, at a cost for removal of \$782.75. These obstructions were all in the 6-inch laterals. Mr. Meriwether, the engineer at that time, also stated, in reply to a question from Mr. William Ham Hall, Engineer of the State of California,

"The omission of manholes caused considerable embarrassment, mainly for want of proper observation and as a means of cleaning out, etc."

Mr. Meriwether also reported that up to that time forty-four manholes had been put in by the city, "none by Waring."

The experience as then reported in our columns at length and the present report of Mr. Hering of that acquired since that time should convince any one of the mistake of trying to reduce the first cost of a sewer system by omitting this very essential feature. We anticipate that a very considerable amount of work will be done during the next five years in the building of pipe-sewer systems, and we present this information feeling assured that it will serve a good purpose, if it enables an engineer to convince committees of laymen who have the matter under consideration that an attempt to save the cost of putting in a proper number of manholes is unwise economy.

THE FALL OF A HIGHWAY BRIDGE IN PENNSYLVANIA.

PRESS dispatches state that a highway bridge over the Juniata River at Williamsburg, Pa., fell on the 18th inst., under the load of a threshing machine and engine, killing one man and badly injuring another. The county owned the bridge, and although the authorities had been notified that the timbers were rotten and unsafe, they had neglected to repair it.

Of course the county is pecuniarily liable for damages to those obliged to use its bridges and to trust the efficiency of its authorities, and those authorities ought to be held criminally liable for the manslaughter due to their carelessness in this instance. This accident adds emphasis to the suggestion in our editorial of last week that public works on whose proper construction and maintenance the lives and property of citizens may depend should be under competent supervision controlled by the State, as town and county authorities are seldom fit to be trusted with such responsibility. Though that suggestion applied primarily to water-works the principle is of much wider application.

THE city of Munich, Bavaria, was long known as an unhealthy place to abide in, and was passed by, or hurriedly visited, by foreigners. All visitors will recall the unpleasant odors emanating from the sewers. The fact was, that the sewerage system was old-fashioned and entirely inadequate

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

W. WHEELER SMITH, ARCHITECT.

to the necessities of the city. This state of things lasted until 1875, when the authorities intrusted to Joseph Gordon, M. Inst. C. E., the task of laying out an entirely new system, which was finished in 1885. The *Wochenschrift des Osterr. Ingenieur und Architekten Vereines* of October 7 gives a description of this important work, which is claimed to be, in its completeness, worthy of one of the most beautiful cities of the German Empire. It is hoped that foreigners will no longer avoid the city on account of bad sewerage, for as a place of residence it is believed by many to far surpass for pleasure, education, and art the cities of Dresden, Berlin, Stuttgart, and Carlsruhe.

REMARKABLE MEETING OF HEADINGS ON THE NEW CROTON AQUEDUCT.

THIS very interesting and unusually successful bit of engineering, which has been noticed in the daily press, is described in detail on another page. So close a meeting is, we believe, unprecedented in the annals of such work, and reflects great credit on the care and skill of Mr. Wheeler and his associates.

The subsequent meeting of headings in the "Northern District" is also a very creditable piece of work, as the error was so small that two 1/4-inch drills would have struck.

RESULTS OF SIX YEARS' EXPERIENCE WITH THE MEMPHIS SEWERS.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: The following is written in response to your request to report the conclusions arrived at from a recent inspection of the Memphis sewerage system while attending the meeting of the American Public Health Association, held in that city November 8-11.

It is now over six years since the sewerage of Memphis, as designed and built by Colonel George E. Waring, Jr., was completed. The deviations that were then made from the principles which had previously been elsewhere adopted—in other words, the "novelties" which entitled the system to be called "Waring system," in distinction from others—have had an ample opportunity to receive a thorough test. In view of the notoriety that had been given to it in this and foreign countries, and of the criticisms made by American and English engineers, and in your columns at the time, it was particularly interesting to see how far the praise and blame were merited, and what real advances the science of sewerage engineering had made.

The works since their completion have been in charge of Mr. Niles Meriwether, Engineer, and Mr. Anthony Ross, Superintendent. These gentlemen have endeavored to manage and extend them as far as practicable in accordance with the instructions left by Colonel Waring, and both from the interest they have taken in securing success for the work entrusted to them and from the results they achieved have proved themselves in every way competent for the task.

For the sake of clearness, let me briefly review the essential features of the "Waring" system in Memphis and point out those which were novel:

First—Exclusion of all rain-water from the sewers. While both in Europe and America the silt-bearing street-water had been excluded from sewers wherever the separate system was adopted, yet no other city had made the attempt to strictly exclude also the comparatively clean roof and yard water.

Second—Soil-drainage by an independent system of pipes leading to separate outfalls. This feature was not a novel one.

Third—Ventilation of the street-sewers through the house-drains and soil-pipes. This practice is in use in a number of European cities.

Fourth—Automatic flush-tanks at the head of all the lateral sewers. Although such tanks had before been advocated and used elsewhere, yet nowhere was it done to the same extent as in Memphis.

Fifth—No manholes on the laterals. This feature was entirely novel.

Sixth—Limitation of house-drains to a diameter of four inches. While this restriction had never before been advocated for a whole city, numerous isolated instances existed.

Seventh—Lateral sewers were to be six inches in diameter until the maximum flow of sewage filled them half full. This was likewise a new feature when applied to street sewers.

The "novelties" introduced by Colonel Waring, therefore, were:

Strict exclusion of all rain-water; use of automatic flush-tanks on every lateral; practical abolishment of manholes; house-drains limited to a diameter of four inches; and lateral sewers limited mainly to six inches.

I shall examine them in this order:

First—While in theory it may be possible to prevent persons from discharging the rain-water from their premises into the sewer, yet in practice it seems impossible. Although strict measures were applied, yet the Memphis sewers began to be so overcharged during rains by surreptitious connections that overflow-pipes had to be laid to the bayou or ditch running through the city, and last year a new 24-inch intercepting sewer, discharging directly into the Mississippi, had to be built across the city to finally relieve the nuisance caused by the storm-water overflows into the comparatively dry bayou. As there is no reason whatever in Memphis why the rain-water from houses should not go into the sewers to flush them and to relieve the property, this restriction cannot be called a good one.

Second—The use of automatic flush-tanks at the head of all the laterals does not seem to have been fully justified in Memphis. The ground is generally sloping and at many points quite steep, and the sewers would in some cases seem to be able to keep fairly clean without daily flushing. The engineer told me this was actually the fact in several instances of new laterals where no tanks had been put in. This shows that a discrimination is advisable for economical construction and maintenance. The best use for automatic flush-tanks is on flat grades, where they are sometimes almost indispensable. They must be considered rather a luxury on steep grades.

Third—The abolishment of manholes on laterals, while strenuously advocated by Colonel Waring, but disapproved of by engineers generally, must be set down as a failure. The frequent stoppages in the laterals, at the rate of about three per week,* and the consequent tearing up of the sewer, would have been avoided had there been proper means of access. Where repeated stoppages occurred manholes have been inserted, and there are now about seventy on the lateral sewers, where at first there were none. In planning for the extension of the system in the northern part of the city, Mr. Meriwether has concluded to place a manhole at every street intersection.

Fourth—The limitation of 4-inch diameter for house-pipes likewise cannot be called a success. Owing to the entrance of rubbish, which seems unpreventable in other cities as well as in Memphis, stoppages are frequent, amounting, according to Mr. Ross, to several every week. The difference between the size of the sewer-pipe and of the largest opening into it must be greater than a 4-inch pipe permits when earthen pipe is used. Experience has amply proven that a diameter of six inches is the only safe minimum for the main house-drain under such conditions. When a 4-inch pipe is relied on it needs a great fall, abundant flushing, and specially well-jointed pipes.

Fifth—The use of 6-inch pipe for street sewers has also shown itself to be an improper restriction. A report of Mr. Niles Meriwether says: "In future nothing less than 8-inch pipe will be used in the branch or lateral lines, as all the obstructions which have occurred in the branches in the past have been in the six and none in the eight inch." The same experience was already had years ago in England, where pipe-sewers were for the first time extensively used; and in America we have since had abundant confirmation. With 6-inch house pipes the 8-inch street pipes have given no trouble.

Every one of the deviations made by Colonel Waring from the principles previously adopted, and strenuously defended by him, have therefore proved to be either of minor importance or wholly objectionable.

An additional point, although not essential to the system as a general one, must not be overlooked. The sewers are often complained of as being altogether too shallow. They are generally from 4 to 6 feet deep and are unable to receive the drainage from cellars.

*Obstructions in 6-inch laterals for six weeks prior to visit:

Two during week ending October 1.
Three during week ending October 8.
Three during week ending October 15.
Three during week ending October 22.
Four during week ending October 29.
Five during week ending November 5.
Twenty obstructions in six weeks costing \$180.35 for removal.

Mr. Ross stated that they should be at least 12 feet deep to do what the people often demand. This depth is the common one in many of our cities, and for a permanent system in a large city it should generally not be less. In view of the great economy required at the time the Memphis sewers were built, it may be questioned whether the expense of twice the present depth would not have been too much of a tax on the people. An ultimate reconstruction of most of the lateral sewers, with greater depth and diameter, seems, however, inevitable.

In summing up, the conclusion seems unavoidable, regarding the essential features of the "Waring" system, as outlined above, that what was new cannot be called good, and what is good cannot be called new.

The successful working of the Memphis system, and it is generally giving satisfaction to the public, is clearly not due to any new features, but to those principles of sewer construction which have been known and practiced elsewhere for many years before, and greatly, also, to the careful and constant attention it receives at the hands of a competent force of five or six men.

Had not these works been so prominently advocated by Colonel Waring and his friends abroad as well as at home, and had not the general public been led to believe that an essential progress had been made in the art of sewer building, criticisms would likewise, I feel sure, not have been given prominence.

In one point Colonel Waring should be given great credit. At the time when it was highly important to introduce sewers in Memphis, and when the city was practically bankrupt, he suggested the separate system as the only feasible one financially against the combined, which had previously been recommended for the city. He suggested it when the system had been but little used in America and only on a much smaller scale than there required. This sagacity and courage proved of great advantage to the fever-stricken city, and the good results which rapidly followed the introduction of sewerage and other sanitary improvements should be and are fully appreciated.

RUDOLPH HERING.

OUR SPECIAL ILLUSTRATION.

COLLEGE OF PHYSICIANS AND SURGEONS.

THE subject of our special illustration is the new building of the College of Physicians and Surgeons, located in New York City, on the northerly side of Fifty-ninth Street, near Tenth Avenue, and opposite the Roosevelt Hospital. The building is isolated and therefore well supplied with light on every side. The material of the exterior consists of brick, with terra-cotta trimmings, and granite sills and lintels. The vestibule of main entrance, which is on Fifty-ninth Street, is wainscoted with marble, with steps and floor of same material.

The stairs leading to each story have a substantial framework of iron; the tread at main entrance being slate, and pine for rear stairs. The wood trimming throughout the entire building is of Georgia pine, finished in oil and varnish. All doors are ash; the walls and ceiling plain white.

The plan of building is in the form of letter T. The top of letter, representing the portion parallel with Fifty-ninth Street, is shown in the vignette; and on the first story of this portion of the building is located the office of the trustees and faculty, students' study, conversation-room, and a coat-room. On second story is the anatomical museum in the centre, with professors' rooms on the right and left. In the third story is located the department of physiology, recitation, and demonstration rooms, with the Swift Museum of Physiological Apparatus in the centre. The dissecting-rooms are located on the fourth floor, over which is constructed a skylight of unusual size.

In the central portion of the building a lecture-room is located on the first floor, with a seating capacity for 460; and directly over it is a theatre, similar in area, but with walls extending the height of two stories, which will also be used for lectures. There is only one elevator, and it will be used for transferring anatomical apparatus to the lecture-rooms.

Each floor fronting on Sixtieth Street is devoted to laboratory purposes. The plant and a section, together with illustrated description of the heating and ventilating arrangements, will be given in a subsequent issue. Mr. William H. Vanderbilt donated \$500,000 to purchase the land and erect the building, and of this sum \$300,000 was expended on this building. The architect was Mr. W. Wheeler Smith, of New York.

REMARKABLE MEETING OF TUNNEL HEADINGS ON THE NEW CROTON AQUEDUCT.

Few people have any conception of the intense excitement felt by all miners at the meeting of tunnel headings, and the meeting, a few days ago, of the headings between the two deepest shafts on the New Croton Aqueduct—Shafts Nos. 2 and 3—was of more than usual interest to the engineers and foremen.

These shafts are located on the First Division, and are under the direction of Charles S. Gowen, Division Engineer. They are 17.5x8, and from the floor of the head-house to invert of tunnel are about 370 feet deep. They are situated 6,200 feet apart. The idea was conceived by Mr. Harry R. Wheeler, assistant engineer in charge, of trying the experiment as to whether it was possible to sink two shafts 370 feet deep and nearly a mile and a quarter apart, and establish lines in the tunnels connecting them with such accuracy as to insure that, before the last 10 or 12 feet of rock was blasted, drills could be set up in each heading on line and grade and the drill-holes made to meet.

On October 31 measurements showed that there was about 11 feet of rock between headings; accordingly, arrangements were made by Mr. Wheeler with Messrs. John McHale, Superintendent at Shaft No. 2, and John P. Small, Superintendent at Shaft No. 3, to have their assistance, and also to have their best drill-runners in the evening.

All preliminaries being arranged, Mr. W. S. Page was detailed to take charge of setting drill in the tunnel from Shaft No. 2, and Mr. Wheeler and Mr. L. C. Easton took charge of the drill in the tunnel from Shaft No. 3. The machine drills in Tunnel No. 2 were set up and started at 8:30 P. M. The rock here was a rather hard limestone, or more properly dolomite, and the drills cut very rapidly and evenly. It was nearly 10 o'clock before Messrs. Wheeler and Easton in Tunnel No. 3 had finished locating the proper position of the drill. Mr. Page at about the same time finished establishing the proper point to begin drilling the centre hole in Tunnel No. 2, and this having been done it was found that neither of the machines on the two columns in the breast could be brought to bear on the centre of the tunnel and at six feet above the invert grade, as had been previously decided. Meantime the drill that was putting in the lower cut hole on the east side in Tunnel No. 2 broke through into No. 3, thus making a hole through which the men in the two headings could converse. No advantage however, was, or could conveniently have been taken of this opening to correct the alignment. Mr. Wheeler, being told that it was not possible, without moving one of the columns in Tunnel No. 2, to set up that drill on the centre line, decided to have the two drills set six inches west of centre line, and this was accordingly done, and the drill in No. 2 started at about 10:30 P. M. In Tunnel No. 3 considerable difficulty was encountered in setting up the drill, and it was about fifteen minutes later when it was started. After drilling about 1½ feet No. 3 drill "stuck" in the hole and caused considerable delay, but was finally started again. Meantime the hole in No. 2 went steadily, though rather slowly, in. At 12 o'clock the No. 2 hole had gone in 5 feet 3 inches and the men went up to their midnight supper; the men in No. 3, however, staid at their drills, as they were late in starting.

When the No. 2 men returned to work at 1 A. M. they turned the machine that had been drilling on the centre hole to another hole, leaving the steel in the hole. When No. 3 hole was 4 feet deep the shock of the drill could be plainly felt by holding the hand on the steel in the No. 2 side. The drill-runners were quite frantic with excitement when it became evident that the holes would meet, and when the Tunnel No. 3 drill struck the first light tap against the drill in No. 2 all work was stopped on both sides for a few minutes and all hands ran about, begrimed with smoke and dirt and yelling uproariously. As soon as the drills touched, No. 3 was stopped, and No. 2 starting again in a very few minutes cut clearly into the No. 3 hole. The drills were now withdrawn and the hole thoroughly "blown out" and cleared from dust, after which a light being held up at one end could be seen at the other. The hole appeared almost round and so straight that it was easy to see a man's eye through it when the light was held properly, and this was the first and most striking fact noted by two colored drill-runners, mutual acquaintances, working respectively in Tunnels Nos. 2 and 3. The holes met almost exactly in the centre, each being about 5'3" deep, and the entire

length of the hole being 10'6" as measured by a steel tape passed through from No. 3 to No. 2 by Mr. Wheeler to Mr. Page. It was arranged to pass the battery-wires through this hole and fire both cuts at once, and lots were drawn as to which shaft should have the honor of "firing," which was won by Tunnel No. 2. The side rounds were fired in the same manner, thus opening a passage between the tunnels after nearly three years' continuous and arduous labor.

When it is considered that these tunnels are very wet and that from suspended wires 375 feet long and only 16.5 feet apart the centre line had to be produced 3,100 feet, it will be readily seen that this is an engineering feat of considerable delicacy. The successful culmination of the experiment was made possible by the cordial co-operation and practical assistance of Messrs. McHale and Small, who staid on the spot with the engineers during the entire night.

The dolomite vein above mentioned is believed, with good reason, to be part of the famous Sing Sing limestone, which crops out at the Prison. This is rather interesting, as the vein encountered in the tunnel is over four miles from the Prison and about 450 feet from the surface.

On the 19th inst. the last headings in the "Northern District" met. They were run from shafts 6,400 feet apart, and 270 and 353 feet deep respectively. The horizontal error in alignment was 0.09 foot, in measurement 0.27 foot, and the error in grade was 0.014 foot.

THE COMPOSITION OF HIGH EXPLOSIVES.

THE following interesting list of the composition of high explosives is from *Le Genie Civil* of October 22:

Dynamite—75 per cent. nitro-glycerine, 22 per cent. bone dust.

Dualine—80 per cent. nitro-glycerine, 20 per cent. nitro-cellulose.

Rendrock—40 per cent. nitro-glycerine, 40 per cent. nitrate of soda or potash, 13 per cent. cellulose, and 7 per cent. paraffine.

Giant Powder—30 per cent. nitro-glycerine, 48 per cent. nitrate of soda, 8 per cent. of sulphur, and 8 per cent. charcoal.

Vulcan Powder—35 per cent. nitro-glycerine, 48 per cent. nitrate of soda, 7 per cent. sulphur, 10 per cent. charcoal.

Mica Powder—52 per cent. nitro-glycerine, 48 per cent. mica.

Hercules Powder—77 per cent. nitro-glycerine, 20 per cent. carbonate of magnesia, 2 per cent. cellulose, 1 per cent. nitrate of soda.

Electric Powder—33 per cent. nitro-glycerine. The balance is a secret.

Dessignolle Powder—50 per cent. picrate of potash and 50 per cent. nitrate of potash.

Brugere Powder—50 per cent. picrate of ammonia, 50 per cent. nitrate of potash.

Tonite—52.5 per cent. gun cotton, 47.5 per cent. nitrate baryta.

Explosive Gelatine—89 per cent. nitro-glycerine, 7 per cent. gun-cotton nitrated, and 4 per cent. camphor.

Atlas Powder, A—75 per cent. nitro-glycerine, 21 per cent. of fibreless wood, 2 per cent. carbonate of magnesia, and 2 per cent. nitrate of potash.

Atlas Powder, B—50 per cent. nitro-glycerine, 34 per cent. nitrate of soda, 14 per cent. fibreless wood, and 2 per cent. carbonate of magnesia.

Judson Powder No. 1—17.5 per cent. nitro-glycerine, the rest unknown.

Judson Powder No. 2—20 per cent. nitro-glycerine, 59.9 per cent. nitrate of soda, 13.5 per cent. sulphur, and 12.6 per cent. pulverized canal coal.

Judson Powder No. 3—5 per cent. nitro-glycerine, 64 per cent. nitrate of soda, 16 per cent. sulphur, and 15 per cent. pulverized canal coal.

Rackarock—77.7 per cent. chlorate of potash, 22.3 per cent. nitro-benzol.

Gelatine-Forcite—95 per cent. nitro-glycerine, 5 per cent. cellulose matter not nitrated.

Gelatine Dynamite, A—97.5 per cent. nitro-glycerine and 2.5 per cent. soluble gun cotton.

Gelatine Dynamite, B—75 per cent. nitrate of potash, 24 per cent. of cellulose matter, 1 per cent. soda.

Gelignite—56.5 per cent. nitro-glycerine, 3.5 per cent. nitrated cotton, 8 per cent. wood bark, 32 per cent. nitrate of potash.

Melinite—Picrated acids, cellulose matter dissolved in ether.

Roburite—Nitrated naphthaline and nitrate of potash.

WIRE-GAUGES.*

A CHART was presented by Mr. S. S. Wheeler, Jun. Am. Soc. C. E., showing the different wire-gauges now in use, who stated that there is no serious fault in some of the existing gauges; the sole difficulty is because so many gauges are in use there is confusion. The cause of this multiplicity and confusion is briefly as follows:

First.—The names of the early gauges were confused, the names of makers and of towns being used indiscriminately, and each gauge being known sometimes by one name and sometimes by another.

Second.—The lack of an authoritative standard and accurate tools for duplicating caused the copies made by different firms to differ among themselves.

Third.—A large variety of new gauges of almost every possible nature have been promulgated within comparatively recent years by the men who have worked and written on the subject, as members of committees and individually.

The first two causes of confusion were more or less natural in the evolution of wire gauges, and may be considered unavoidable. The third, the introduction of new gauges, is going on at the present day, and ought to be stopped.

The result of there being no law of formation of these gauges is that among the English gauges there are more than a dozen Birmingham and many "Old English," "Old London," "Warringtons," etc., giving different values for the same number, between gauges of the same name, simply because each maker, having no fixed relation between the sizes to go by, copied some old pattern which was inaccurate from wear. The existence of this nebula of irregular old gauges is the chief cause of the unintelligent outcry against gauges. There is none of that variation between copies of either the Brown & Sharpe or the Latimer Clark, both built upon a fixed rule.

Of the thirty-one existing gauges, the American, or Brown & Sharpe, the one by which copper, brass, gold, etc. (all wires except iron and steel), are measured in America, is the only one that exactly fills the requirements considered. It is a perfect parabolic curve, with a uniform reduction of eleven per cent. between consecutive sizes. The only other gauge which approaches it in the two leading requirements, a range of sizes which covers the wants of wire-users without useless intermediate sizes, and regularity of increase of the sizes, is the Latimer Clark's proposed standard. But this has not been much used, is unfamiliar, and has not been extended in sizes finer than No. 22 American gauge.

The proposition frequently brought out, that the micrometer should be used exclusively, indicates that there is a widespread failure to realize what the wire-makers want. The majority of manufacturers have neither the time, skill, nor need for the micrometer. They want a rough notch gauge adapted to sorting out the sizes which they draw, and as simple and as easy to read as possible. There is no use in recommending or condemning the micrometer. It is used, and, notwithstanding any condemnation, will continue to be used in all accurate work, as it is indispensable.

The detailed description of chart was listened to with great interest. Mr. Metcalf followed by stating that in the works he was connected with the micrometer was in general use for all grades of work, and the workmen preferred it to any other.

ABATTOIRS IN THE UNITED STATES.

AN English correspondent inquires for any publications giving reports on this subject. The following is all that is known to us, though possibly some of our readers can suggest something new.

[Probably the only public abattoir (in the European sense of the term) in this country which has any special interest is that in the city of Boston, known as the Brighton Abattoir. See

1. Report Board of Health, State of Massachusetts, VI., 1875, p. 187; also Vol. V., 1874, p. 155.

2. The Brighton Abattoir, owned by the Butchers' Slaughtering and Melting Association. 8vo. Boston, 1878. (Text English and French.)

3. American Public Health Association Report, Vol. VI., for 1880. Boston, 1881. p. 217-231.

These books can probably be seen at the Parkes Museum of Hygiene in London.

The large private slaughtering establishments in Chicago, Cincinnati, etc., have never been properly described or illustrated.]

* Abstract of paper read at the November 17 meeting of the American Society of Civil Engineers.

SOME SKETCHES OF PLUMBING IN THE
RESIDENCE OF WILLIAM F. WELD, ESQ.,
BROOKLINE, MASS.

No. II.

(Continued from page 712.)

WATER-SUPPLY.

A FEATURE of the water-supply of this residence is two water-tanks, one at a higher level than the other. The difference of level is not a matter of choice, but of necessity, as one, the upper tank, is in the attic of the main building, while the lower one is in the attic of the extension which contains the laundry, etc.

All the fixtures in the house can be supplied from the upper tank, and all fixtures in the lower part of the house can be supplied from the lower tank, but at a reduced

board supply bath-room and water-closet, etc., upstairs. The second pair of cocks on the switch-board supply the laundry and servants' quarters when necessary. The third pair of cocks, the lavatory, and water-closet, etc., in the lower part of the house, and the lower pair of cocks, the milk room, and the servants' dining-room; the manner of supplying the kitchen being apparent.

A study of the diagram shows how the pipes H and C, corresponding to the second pair of faucets, may be followed to the laundry. They run direct to the end of the wash-trays and return with Y-bends into the lower ends of the laundry supply. The faucets shown both in diagram and in laundry just above the Y-bends are kept closed when the laundry-boiler is in use, but should it be necessary to use water from the kitchen-boiler in the laundry, they are opened and the lower tank shut off. In the diagram, the valves to shut the lower tank off is shown below the branch to servants' bath, etc. This is a mistake, as they should be above. To the practical man a study of the diagram will show other combinations in which the water from the low tank may be admitted to parts of the front building when the high-tank service is not in use, by the manipulation of the switch-board valves, etc.

FIGURE 4.

pressure. The object of separate tanks, however, is to admit of a water-supply in the servants' quarters and laundry when the other part of the house would be unoccupied, as, say, in winter time, at which time the water-pipes, etc., would be drawn off to prevent freezing and the traps filled with glycerine or some non-freezing mixture. The arrangement, however, also admits of using different waters in different tanks; for instance, well or city water in the high tank and soft water or cistern water in the low tank for laundry.

The diagram, Fig. 4, shows this arrangement of tanks and pipes in principle, and is, so far as the kitchen and laundry pipes are concerned, an exact reproduction of the pipes of the house, as may be seen by a study of the kitchen and laundry illustrations, Figs. 5 and 6. Like letters in different figures have reference to the same pipes when seen again.

To trace the cold-water supply from the upper tank we follow the pipe C on the right of diagram, Fig. 4. It is also to be seen in the kitchen on the ceiling. This pipe goes to the switch-board in kitchen, forming the right hand or cold line of supply to all parts of the house.

The second pipe from the bottom of the upper tank supplies the kitchen-boiler direct. From the boiler the warm-water pipe H runs to the kitchen-sink in one direction and to the left-hand side of the switch-board in the other direction. The two upper cocks of the switch-

The general arrangement of the kitchen can be seen in Fig. 5. The floor is oak. The wainscoting behind sink marble. The part behind the switch-board white-glazed tiles. The walls are oil-painted. The chimney-breast is of white-glazed bricks. The sink is of soapstone, supported on oak frame, with brass legs. The boiler is eighty gallons capacity, extra heavy.

The laundry boiler is forty gallons capacity and is connected to a separate stove and coil. A separate open boiler for boiling clothes, etc., is also used, as shown in the corner. This arrangement, the convenience of which is obvious, is peculiar to the vicinity of Boston. The

FIG. 7.

arrangement of the tubs, which are soapstone, is shown. The waste-pipes are lead and a casual look gives the idea of more connections than there are tubs, but this is explained by the fact that the supports or hangers from the bottoms of the tubs are made to correspond to the waste-pipes in appearance.

The walls are glazed bricks and the floor buff tiles.

Figure 7 is a detail of the overflow-pipes of the tanks first described, and as the pipes are all marked it requires no special description from us.

CORRECTION.—In the first article on this work, published in our last issue, we were in error in stating that the drainage is to the city sewer. It is to a system of sub-surface disposal laid out by Messrs. Aspinwall & Lincoln, of Boston.

(TO BE CONTINUED.)

FIGURE 6.

FIGURE 5.

MAKING VERSUS BUYING SOLDER.

SIR: We have always found it better and cheaper to make our solder than to buy it.

We have saved twenty to twenty-five per cent. in the cost of manufacture, and have had a solder that would hold its own until all used up. The solder we have bought has always turned up "coarse" after a few heats of the pot. We have always kept the weight of the tin and joints, and know how much solder we made.

Here is one sample: 202 pounds "Straits" tin melted with 500 pounds solder-joints (cut out) made 656 pounds solder.

BRICK FURNACE FOR MELTING SOLDER

This solder is far superior to any we can buy. In regard to the trouble you speak of about the purity of the joints, we heat the old joints in a large iron cauldron set in a brick furnace. I enclose sketch. When the metal is red we put in a stick of sulphur, which, when stirred in well, purifies the metal. Add your tin, and try making a joint before running off the metal.

Respectfully, W. G. N.

A SEWER STOPPED BY TREE ROOTS.

OUR Milwaukee correspondent reports a case of the roots of a tree stopping up a sewer, which was found by a Milwaukee plumber last week. Being unable to clear the sewer from the cellar, it was dug up outside and found

choked up solid with tree roots. The roots were matted together and made a very solid mass. The sewer is made of cement pipe and was laid wrong end to—i. e., with the hub ends toward the street. The sewer was only six feet deep and the joints were not made perfectly, some being only half cemented. The roots extended out into the street and for a distance of 40 feet into the house—i. e., 40 feet from curb. The roots were both inside and outside the sewer and followed it in the trench for 20 feet inside the cellar.

THE NEW SECRETARY OF THE NATIONAL ASSOCIATION OF MASTER PLUMBERS.

NATIONAL ASSOCIATION OF MASTER PLUMBERS
OF THE UNITED STATES,
OFFICE, 54 UNION SQUARE,
NEW YORK, November 22, 1887.

SIR: In accordance with the resolution of the National Convention of this Association at Chicago, the Executive Committee has appointed Mr. John C. Welch, Grand Secretary, with his office at 54 Union Square, New York City.

Mr. Welch will have charge of the correspondence and he will be pleased to hear from and communicate with the members and friends of the association on all subjects pertaining to its prosperity and usefulness.

Yours truly, JOHN BYRNS, President.

Correspondence.

PREVENTION OF FIRES IN THEATRES AND PUBLIC BUILDINGS.

In response to request for information on this subject (see item, page 712, issue of November 19), as regards Boston and vicinity, we have received the following from Mr. C. J. H. Woodbury, M. Am. Soc. C. E.:

"BOSTON MANUFACTURERS' MUTUAL FIRE INSURANCE CO., 31 MILK STREET, BOSTON, November 19, 1887."

"SIR: The United States, State, and city buildings in Boston are protected by stand-pipes with hose at each

story and fire-pump in the basement. They are also furnished with a large number of portable extinguishers. The hospitals have special yard hydrants and stand-pipes, all of them supplied by city water alone without the addition of any pump. The school-houses are provided only with extinguishers. These buildings are also provided with what are called special boxes connected with the fire-alarm.

"The theatres are protected with special hose and extinguishers, and a fireman in full uniform is detailed on the stage at every performance. Over the stages of two theatres there are automatic sprinklers, and over some of the stages there are skylights, with wire netting below, for the purpose of affording relief from smoke which would be drawn over the stage and away from the auditorium when the glass is broken by a slight fire. One theatre has an iron curtain and another a curtain of asbestos; all doors open outward, and the number of doors and other precautions are added according to the discretion of the inspectors of buildings. The theatres are swept after every performance as a precaution against matches or any other dangerous matters, as well as for the orderly conduct of the theatre. There is also a special electric connection to the fire department without striking a public fire alarm.

"I believe that automatic sprinkler protection over the scenery and store-rooms of every theatre is a precaution which ought to be required by law. In the industrial property insured by this company their use has been followed by results which are producing an economic revolution. We had last year ninety-nine fires put out by such apparatus, with an average loss of less than two hundred and fifty dollars, while the average loss of fires to date starting under the Grinnell sprinkler has been a little more than a hundred dollars, that being more sensitive to heat than other types of sprinklers.

"The result of this improved protection has diminished the cost of insurance in the Mutual companies about three and one-half million dollars during the last eight years. The average cost of fires starting where there is no automatic sprinkler protection is about seventy-five hundred dollars. If I can provide you with further information upon this point, let me know, and I will be very happy to comply with your request if in my power.

"Yours very truly, C. J. H. WOODBURY.
"Second Vice-President."

EFFECT OF TEMPERATURE ON TRANSVERSE STRENGTH OF IRON AND STEEL.

SIR: Mr. Ramsey's letter in THE ENGINEERING AND BUILDING RECORD of recent issue introduces a subject to which few, if any, structural and inspecting engineers have not given some consideration, and further discussion seems desirable. That tool steel or any steel high in carbon, or perhaps manganese, is vitally affected by temperature changes below (say) 60° Fah., seems incontrovertible. Every iron erector will verify the cold-chisel illustration, and doubtless many steel rails, which are so generally of high steel, are much indebted to low temperature for their breakages; but all of my own experience and observation is that properly worked, clean wrought iron or low steel, free from impurities, experiences little, if any, effect from the climatic temperature changes in this country. The 12-inch channel tests mentioned have merely the weight of a not remarkable coincidence: the breakage of the channel in the field may not have been surprising. No data are given, but if the piece was a 12-inch 30-pound channel, 30 feet long, and fell the 10 feet and struck on its centre, flatwise, the strain of flexure alone would have been 81,000 pounds total, — 9,000 pounds per square inch, uniform, or 22,000 pounds per square inch at outer fibre, but these results should be doubled for the suddenly applied load, so that without considering the violent destructive effect of impact we have conditions of breaking which, of course, increase or decrease directly with variation of the assumed from the actual weight and length. I have had a perfectly good 60,000 or 70,000 pound steel angle, 3½x3½x50-feet, break by flexure in a warm shop, simply by being gently lifted by a sling at the centre.

A channel, too, is a most undesirable section. Everyone knows of the initial strains necessarily existing in it, its warping on the hot bed and restoration (?) by the gag press; and, as in every piece of piled iron, there is the chance of old rails, and the certainty, in case of a channel, that the material of the web is different from that of flange.

These considerations make results of tests of specimens cut from same bar always likely to vary, and contradictions probable.

The nicked test of iron is an uncertain criterion; a piece broken after nicking with a dull chisel often develops a crystalline fracture, when an adjacent piece nicked by a sharp chisel does not. Low steel (0.15 per cent. carbon) is essentially a pure wrought iron, and the better the latter becomes the closer the identity. In hundreds of tests made within the last two years on Bessemer and Clapp-Griffith structural steel up to about 0.18 C., I have

noticed no indications that they were affected by differences of temperature. In bending 90° to 180° about a small radius, a thick piece of iron or steel develops enough heat to almost burn the naked hand, therefore the internal condition must speedily become independent of external temperature. Most important is the fact that in perhaps 500 cases where pieces of the same specimen of low steel were bent, both naturally and after heating to cherry red and quenching in water of 60° to 70° Fah., there not only was no decided difference in results, but it was even apparent that a variation of 40° in the temperature of the water, or in that of the steel from a dull red to orange, had no appreciable effect.

Bending and breaking tests, whether nicked or not, depend vitally on the skill and carefulness of the experimenter, and it is to his ability, rather than the specifications, that attention should be directed; for while a good test can hardly be secured from bad material, very bad tests may easily be got from good material, and it is believed by many observers that in very many cases of fracture by nicking and impact, the structural appearance is not that originally existing, but has been induced by the applied forces and conditions at moment of fracture—i. e., the texture or crystallization is not the cause, but the effect.

In this connection I beg to enter protest against sledging-tests, believing that, with the proposed impact test, they are unjust, illogical, and useless, by no means indicative of the qualities sought; no simple material or trussed structure should be subjected to parallel conditions in actual service, and if, as is generally alleged, the point desired is evidence of its ability to undergo shop manipulation, it would be better, easier, and cheaper to specify punching or shearing tests. There should undoubtedly be a prescribed standard for length of arc and manner of bending test pieces. Sledged bends, either by direct impact or intermediate contact, are brutal; bending under a steam-hammer is variable even when accomplished by weight pressure alone, much more so when effected by repeated blows; bending by pressure into a die or between supports is hardly better.

The most simple, reliable, and uniform method is by confining one end of specimen by a back stop, and with radial arm and friction roller contact bending the other end around a centre pivot with collar of diameter required for inside of curve.

The conditions of speed and train load do, and doubtless should, remain constant for the same structure throughout the varying temperatures of the year, and I am not aware that special precautions are observed on Canadian or North-western railroads, or that accident and destruction has occurred to their bridges as often as to some in warmer latitudes.

Nevertheless, when the imperfect seats, poor alignment, open rail-joints, effect of curves, and above all, the violent blow from every revolution of a flattened wheel is considered, there is sufficient reason for prohibiting high speeds at any time on any structure, unless it be a solid girder of excessive rigidity and fractional unit strains.

FRANK W. SKINNER.

THE ARCHITECTURAL DESTRUCTION OF NEW YORK CITY HALL AND PARK.

NEW YORK, November 17, 1887.

SIR: I am so pleased with your remarks in your issue of November 12, and so shocked at seeing the sketch which you give of the proposed additional buildings in the City Hall Park for the criminal courts, that I cannot allow the opportunity to pass without entering my protest against the desecration.

Morris wrote, "Woodman, spare that tree!" Can we not, with ten times the feeling, write: "City officials, spare our park! spare our City Hall!"

It seems to me, if the design is carried out as suggested, our beautiful City Hall will become a monstrosity. It cannot be made much else.

Just imagine buildings being put there in such close proximity to the Hall when we have so little left of our park. It was bad enough to build the Court-House where it is, far worse to build the brown stone engine-house, and to sell the lower end of the park for a United States Court-House, but all these pieces of stupidity pale in comparison with this project.

Here we are about to spend \$8,000,000 to \$10,000,000 for parks in the upper wards, and \$1,000,000 to \$2,000,000 for small parks in the lower part of the city, and yet our Mayor, who is so sensible about many things, lends his voice for curtailing the little there is left of the only park below Washington Square, save the Battery.

There would be some excuse if our prison was in the park, for it and the Court-House should be near each other, or if we did not own a block opposite the prison exactly suited for the purpose. Can we not arouse public sentiment enough to cause our officials to pause and leave us, in its beauty, our City Hall? for, old as it is, it is a most beautiful building, and reflects great credit on its designers, and we in these later days should not allow dollars and cents to blot out all our sense of the beautiful and good.

Yours truly, HUGH N. CAMP.

THE WATER-WORKS CONSTRUCTION CRAZE AT HELENA, MONTANA.

MR. T. C. POWER, of Helena, Montana, General Manager of the Benton Transportation Company, writes us regarding water-works construction in that city as follows: "Helena, Montana, has been running wild for the last thirty days in the construction of water-works. Three companies have been digging ditches throughout the city, and in one street the three ditches, representing each company, are paralleled. George F. Woolston, representing the new company, has laid about twelve miles of pipe and is working 700 or 800 men. The Helena Water Company has extended its mains and has laid nearly four miles of pipe. Mr. Chesman has laid about two miles of pipe. The Helena Water Company and Mr. Chesman have the gravity system, with more than enough of water to supply a city twice as large as Helena. The Woolston scheme has been to sink wells, and they expect to pump their water to an elevation of about 450 feet. This will cause a great outlay of money continually. The outcome can be easily determined by any sane man. They have, after working hard since last June, at great expense, succeeded in getting about five or six hundred thousand gallons per day from their well—not sufficient by a third to supply their pipes. This is a true statement of the Helena, Montana, water-works industry."

MACHINERY FOR MAKING SEWER-PIPE WANTED.

VICTORIA, B. C., November 14, 1887.

SIR: Could any of your readers favor me with the address of a firm who manufacture or sell machinery for making sewer-pipe? Yours truly,

SAMUEL C. BURRIS, Architect.

THE FALL OF FIVE DERRICKS AT THE NEW COURT-HOUSE, BOSTON.

WE have received the following letter from one of the Commissioners for the Erection of a New Court-House for the county of Suffolk:

BOSTON, November 22, 1887.

SIR: I have just noticed your diagrams, etc., and read the report of the cause of the falling of the derricks at the new court-house site, which is *not correct* in some particulars, and which will be more satisfactory to you to have corrected. The support to the cross-timbers was placed about two feet to the left of the mast, not directly under it, as shown, and the weight of load added to that of the derrick tilted the left arm of the cross-timbers, so that the support and one wall took the load, and was not sufficiently rigid to overcome the leverage of weight at the end of the boom. Had there been a 3x4-inch joint used to brace the support in line of cross-beams, no accident would have happened (probably).

Respectfully yours, THOMAS J. WHIDDEN.

FOURTH ANNUAL CONVENTION OF THE WESTERN ASSOCIATION OF ARCHITECTS.

(Special Correspondence.)

WEDNESDAY, Thursday, and Friday, November 16, 17, and 18, 1887, were great days among those members of the Western Association of Architects who attended the convention of their society held at the Grand Hotel, Cincinnati, where the committees had headquarters, and the spacious corridors of the "parlor floor" afforded room for a large and fine display of architectural drawings.

At 11 o'clock on Wednesday morning, in the large convention room of the hotel, President John W. Root, of Chicago, called the association to order and read an opening address, which, if space permitted, we should like to reproduce in its entirety. In reference to the much-discussed question of professional ethics, Mr. Root said:

"Each must have most nearly at heart the interests of all, and must be prepared, at any time, and for the ultimate good of all, to surrender small and temporary personal advantages. We are all in this Union upon a level plane. The heads of some may tower above, but the feet of none may stand below those of their brethren.

"This being true, as a matter of theory, how shall it be realized as a matter of practice?

"First, let us answer, by cultivating among ourselves relations of perfect understanding and friendship.

"Men are so largely influenced by personal ends that no relation can ever be established so ideal in its common help and consideration as that existing between two friends; and I am persuaded that, out of any ten of the grievances one of us may in professional practice have suffered from another, nine will be found directly traceable to misapprehension and consequent estrangement.

"The short way to avoid these grievances is to cultivate such warmth of personal relationship that no man of us need for a moment hesitate in any case of doubt or possible distrust to ask of his friend full and free explanation. Once this state of affairs is brought about our code of ethics unites and enforces itself, and until it is brought about any code of ethics is inadequate."

Mr. Root went on to say:

"The thing to insist upon is thought, not dexterity of pencil or newness of fad, but full expression of one dominant and well-thought-out idea.

"Idea is the crying need of our modern architecture. * * * Architecture is the material expression in stone and iron and brick of an idea dominating, consistent, coherent. * * *

"Be it ours, therefore, to infuse into our work, that earnest thought which will make it lasting."

After the opening address came the reports of various committees.

Mr. Sullivan, chairman of the committee appointed to effect certain alterations in the code and to devise means of maintaining an elevated standard of membership, read an excellent and practical report.

This committee had prepared a blank to be filled out by the applicant for membership, giving name, place, etc., with the name and address of three architects and three men of good standing outside the profession willing to answer the questions on a printed form to be forwarded by the examining committee. These answers to be regarded as strictly confidential. Only such questions will be asked as are necessary to ascertain that the applicant is a man of honorable character.

The applicant must also inclose with application three photographs of buildings erected by him, giving location of each and name and address of owner and contractor.

Before admission an opportunity will be given to members to object to any candidate, such objection to be made the subject of careful private investigation by the examining committee.

The Committee on Statutory Revisions recommended renewed efforts to secure the adoption of an enactment similar to that presented at the St. Louis Convention for the regulation of the practice of architecture, and proposing a radical reform in the erection of the buildings of the National Government.

A long report was received from the Committee on bill governing the office of the Supervising Architect in the U. S. Treasury Department, which was accepted and ordered printed in full in the report of the convention.

Wednesday afternoon was given up by the association to a long drive through the various suburbs, and to viewing the principal objects of architectural interest in and around the city. The convention reassembled at 11:15 A. M., on Thursday.

The Treasurer's report having been received, and also that of the Committee on Metrical Measure, and one ordered upon the subject of uniformity in contracts and specifications, Mr. D. Adler proposed the consideration of the consolidation of all the architectural associations, and a committee of five, including the president, was appointed for that purpose, to co-operate with the committee of the American Institute.

The members of this committee are: J. W. Root, D. Adler, George B. Ferry, W. W. Carlin, A. Van Brunt, and a report was ordered to be made by the 1st of August, 1888. Then followed balloting for new members, when eighty candidates were presented, and this having been disposed of the following officers were elected:

President, Sidney Smith, Omaha, Neb.; First Vice-President, J. S. Alexander, Lafayette, Ind.; Second Vice-President, W. C. Smith, Nashville, Tenn.; Secretary, N. S. Patton, Chicago; Treasurer, S. A. Treat, Chicago.

Board of Directors: J. W. Root, Chicago; W. R. Forbush, Cincinnati; J. V. Flanders, Chicago; C. F. Schweinfurth, Cleveland; George B. Ferry, Milwaukee, Wis.

The President-elect, Sidney Smith, was the unanimous choice of the nominating committees. He was a pioneer in the association, and is a member of the Royal Institute of British Architects.

On accepting his re-election to the office of Treasurer, Mr. S. A. Treat made the following pithy speech: "Membership dues for 1888 are now payable."

A vote of thanks to the Art Museum for courtesy in extending an invitation to visit it, and also to Messrs. G. K. Shoenberger, A. R. Vail, and Alex. McDonald for opening their private residences to the association, was next in order. A resolution on the death of Thomas U. Walter, late President of the American Institute, was also passed, and a vote of thanks was given to the Commissioners of the Exposition.

The convention adjourned to meet next year at Chicago.

The papers read will be noticed in subsequent issues.

THE PARAMOUNT REQUIREMENTS OF A LARGE OPERA-HOUSE.*

OUR secretary has requested me to submit a paper upon "The Paramount Requirements of a Large Opera-House or Theatre as regards site, construction, disposition of space, day and night illumination, arrangements for water-supply, ingress and exit, heating, ventilation, hygiene generally, and provisions against conflagration, etc."

The following is an effort to comply with this request:

As we are all American practitioners whose work is confined within the geographical limits of the United States and therefore within the financial and other limitations arising from our National peculiarities, I will make no effort to describe the ideal large opera-house, of which so many examples exist in Europe, but will confine myself to the essentials and peculiarities of an American theatre and opera-house containing upward of 3,000 seats and capable of serving also as a concert or convention hall.

The site of our building should be an open square surrounded by broad streets; but in no case should a site be chosen which does not permit the disengagement of the building on at least three sides.

The construction of such building should be of the most solid and enduring materials, so disposed as to produce a building as nearly fire-proof as modern science and art can make it. The ever-changing conditions of desirability of location so characteristic of American cities must be disregarded by making stability and permanence of structure paramount considerations.

In the disposition of space we are confronted by limitations which prevent the fulfillment of ideal requirements. Municipal aid is with us never extended to the builders of an opera house, which must therefore be erected by private capital, of which it seems impossible to secure as much as is required for erection and maintenance without connecting therewith some means of commercial utilization, so that a revenue sufficient for the maintenance of stage and auditorium during the many periods of disuse may be obtained.

This disposition of important parts of the ground, generally the street frontage, increases the difficulty of planning the lobbies, foyers, and corridors so desirable for a structure of this kind; but whatever the wants or necessities of the commercial adjuncts of such building, there should always be lobby space enough to hold almost the entire audience.

In determining the space to be assigned to the stage, it must be remembered that without suitable provision for presenting to the public scenic and dramatic effects on a far grander scale than can be produced in the ordinary theatre or opera-house, there would be no justification for the existence of a building of the class which I am endeavoring to describe. And yet, too much space should not be assigned to the stage, as the commercial result of the enterprise must be kept in mind, and this requires a reasonable proportion between the cost of producing a good opera or a spectacular theatrical performance, and the size of the audience which can be drawn to see the same. We have no subsidy from municipal or general government to make good deficiencies which would arise from the cost of performances given upon a stage of the proportions, as compared with auditorium found in the opera-houses of the old world. Besides, we cannot in any city of our country maintain, still less carry with a traveling company, a permanent well-trained chorus, corps de ballet, or a corps of trained supernumeraries sufficiently large to fill a stage approximating in size that of a European house of the first rank.

A very large space should be assigned to the mechanisms for the production of scenic transformations and illusions. Nothing is more annoying to American audiences than the excessively long waits between acts so characteristic of operatic performances on a large scale as we know them on the American stage. And while the almost magic transformations characteristic of the stage of the Madison Square Theatre are impossible of attainment under ordinary conditions, I believe that a happy mean can be found between these and the evil before referred to. One of the means of securing this end would be an effort to keep all moving and movable parts incidental to the production of scenic effects, transformations, etc., within reasonable bounds as to size and weight, and, as far as possible, to make transformations by upward and downward movement of the stage paraphernalia, by which means the horizontal dimensions of the stage can be minimized, although great depth below and height above the stage floor would become essential. Liberal allowance of space for dressing-rooms, and for storage of scenes, properties, and costumes must not be forgotten.

It is advisable to endeavor to secure at least partial sunlight illumination of the house, and thus avoid the expense of artificial illumination for daily cleaning, rehearsals, and for daylight assemblies, such as conventions, mass meetings, concerts, etc., when scenic effects are not to be produced. This daylight illumination will be almost invariably imperfect for corridors, lobbies, etc., and in many instances the business adjuncts of the building will cut off all means of illumination except skylights, and these can rarely be made sufficient to light up all parts of the house. Means must be provided to shut off, when necessary, all sunlight which might interfere with the realization of scenic effects.

Day and night illumination of the auditorium and stage when occupied for a scenic representation of any kind must be by artificial light. Of the artificial lights known to us, the incandescent electric-light is the only one to be

seriously considered, in the design and distribution of which every effort should be made to secure a uniform and general illumination—a lighting up of all shadows under galleries, and an illumination which will reveal clearly all faces and toilets without bringing them into a trying glare. In arranging the lights of the stage, it is necessary to see to it that the light falls upon the faces of the performers in such manner that there will be no shadows which produce distortions of their features. It is well, also, in arranging lights, particularly those on and immediately in front of the stage, to interpose reflecting surfaces which throw the light where it is required, and shut out its glare from the direct line of vision of the audience.

In the construction and laying out of the engines, dynamos, and wiring for electric-light, an effort should be made by suitable subdivisions to prevent the possible putting out of all the lights by an accident to the machinery or wires. The practice of European theatres in providing as a safeguard for such a contingency a system of oil lamps or wax candles arranged and always kept burning around the walls of the auditorium and in all the corridors is worthy of imitation.

The means of ingress and egress should, of course, be ample. No allowance less than three feet for every 200 persons in determining the width of aisles, doors, and stairways should be considered. A large number of narrow aisles is to be preferred to a small number of wide ones. Aisles should lead as directly as possible to doors. As before stated, the corridors and lobbies should be of sufficient size to hold more than one-half of the audience. The stairways must have frequent landings and the exits should be so disposed as to tend to disperse the audience as rapidly as possible.

Where audiences are very large the means of ingress become quite important, and every facility must be extended to those who purchase their tickets at the beginning of a performance, and these should be kept out of the way of persons who come already provided with tickets, and every means must be used to facilitate the entrance of the public into the building, and to prevent blocking up of halls, corridors or stairs.

Heating and ventilation present unusual difficulties in a house of this kind. No dependence whatever can be placed upon doors and windows. The air must be warmed in winter and cooled in summer. A sufficient volume of air for comfort and for health must be forced into and removed from the room by mechanical means. The temperature and hygrometric condition of the air admitted must be under perfect control, and the means for exhausting the air must be so arranged that the vitiated air in its progress to the exhaust ducts does not come in contact with the heads of any part of the audience and that "draughts" are prevented. It is desirable for acoustic effect to have all air-currents tending from the stage outward. It will be easiest to attain these ends if the fresh air is chiefly introduced at and from the top and in greatest volume near the stage, and if the exhausts are in and near the main floor and in and near the floors of the various galleries and balconies, increasing in capacity with their distance from the stage. One-third of the air-ducts should open on the stage, but these ducts must be under the immediate control of the prompter, so that they may be closed when smoke is produced on the stage and while the curtain is lowered and turned on again as the curtain is raised.

Wherever possible the galleries should be disengaged from the walls behind them so as to permit the free passage of air-currents through the space covered by the gallery.

As a protection against draughts from out doors, there should be, if possible, at least four sets of doors between the chief lobbies and the outer air, and each of the spaces enclosed by these doors should be warmed.

The means of cooling the air for summer ventilation must be refrigerator machines. It is impossible to handle successfully a sufficient quantity of ice for our purpose. In dusty and smoky cities, an apparatus for washing the air before it is introduced into the building should be provided.

As it would be too expensive to call into use the means of heating provided by the ventilating system for the daily cleaning of the house and for rehearsals, there should be a sufficient quantity of direct radiating pipes and coils on the stage and in the auditorium to warm the house to a moderate extent. These would not be used when the house is occupied by an audience, except perhaps in the coldest weather.

Foremost among the necessary hygienic arrangements is the system of ventilation before described. Next in order are the plumbing fixtures and pipes, upon which even greater care must be expended than in ordinary buildings. During the periods of disuse to which houses of this kind are subject, the evaporation of water from the traps, or syphonage of traps, or leaks of soil or waste pipes would produce most disastrous results. These contingencies must be therefore guarded against with the utmost care. During these same periods of disuse in winter the danger by freezing of water in the pipes is a danger against which precautions must be taken.

The provisions against conflagration are a most fruitful topic. As it has been assumed that the general construction of our house must be fire-proof, we have in this already a most potent safeguard against conflagration. If we carry this fire-proof construction further and use for the frame-work of the stage, stage mechanisms and paraphernalia, incombustible materials and banish gas from the stage entirely, using only electric-light not only for white

light, but also for the effects of colored light, we shall have eliminated entirely the danger of disastrous conflagration from our house. It will, however, be impossible to avoid entirely the use of canvas for scenery and the use of wood for the lighter and more temporary accessories of stage setting, and the large quantities of costumes and properties which accumulate about such a house are necessarily combustible. While a fire among these cannot be considered a menace to the structure, still there should be means at hand for readily extinguishing it; there is a choice, such as a system of automatic sprinklers or the thorough training of the stage attendants in the use of water in the tanks and pails, in the use of hand-pumps, hand-grenades, chemical fire-extinguishers, etc.

But although the building be indestructible by fire, and although the gathering of headway by a fire is almost absolutely guarded against, alarms and frights may arise which in so large an audience would have serious consequences. A strong drop-curtain of incombustible material used daily, so as to be always in readiness for instant use in an emergency, will shut off from the view of the audience the accidental burning on the stage of small pieces of scenery, etc., as may have been left unprotected. A very large and high smoke-duct above the stage, the valve of which is connected with the prompter's stand will permit the immediate and rapid escape of smoke produced by such fire, or by the use of firearms, etc., on the stage.

It is safe to assume that an audience in a house of this description is absolutely safe from fire; that is, that no combination of circumstances can arise by which any member of the audience can be injured in life or limb directly by the effects of the fire. There always exists, however, an element of danger in the liability in large assemblies to become panic-stricken and uncontrollable. The general solidity of construction and general safeguards against fire mentioned before will do much toward preventing the formation of a panic in the audience. Arrangements for averting the danger of the going out of all the lights in the house will eliminate another serious possibility of panic and danger.

The foregoing provides sufficiently for the safety, comfort, and health of the audience; but all of these will be as naught unless the acoustic properties of the house are such as to permit the easy and distinct transmission of articulated sound to its remotest parts. The suggestions given under the head of ventilation will be one of the means necessary for securing this end.

In addition to this, it should be said in a general way, that in the construction of the banks of the seats Scott Russell's isacoustic curve should be adhered to as far as practicable; that, wherever possible, resonant materials should be used in the construction and facing; that large, hard, smooth surfaces should be avoided; that walls and ceilings should be well broken; that the width and height of the house should be least at the stage, and that these dimensions should be increased with the distance from the stage, and that all our measures should tend toward the reduction to a minimum of the volume of air to be set in motion by the voices of speakers and singers; also to such arrangements of surfaces as will tend to direct the sound waves toward the audience, and such control of the air-currents as will prevent the dissipation of sound-waves in space.

I will add, in this connection, that a comparatively low proscenium and not excessively wide opening is desirable as one of the first conditions of this system of construction for acoustic effect. If it is intended to use the house for conventions, or concerts by mammoth choruses, the proscenium opening may be so constructed as to leave its width adjustable at pleasure, and a temporary ceiling may be suspended at or near the level of the crown of the proscenium arch over the stage, and hung with a downward slant toward the back of the stage.

As I have said before a modification of Scott Russell's isacoustic curve should be used in laying out the banking of the seats. This modification is for the purpose of obtaining an isaoptic line and consists in shifting the level of the focus to which the curves are drawn from the level of a speaker's mouth to the floor line at the foot of the stage, and in substituting for a single focus to the middle of the stage, foci tending toward the sides of the curtain opening for the respective sides of the house, so that the focus of the curve for the seats nearest any one side is at a corresponding jamb of the curtain opening.

It may not be always best to follow the foregoing absolutely for the selection of foci in isacoustic and isaoptic lines, but the deviation should never be great and the nearer the approach to these conditions the easier will be the sight lines for all occupants of the house. It will be found as one of the effects of an adherence to the foregoing that long, wide side galleries must be banished.

As Mr. Bloor has well said in his letter requesting this paper, "Style is generally conceded to be a matter of taste, chiefly dependent on education or temperament, environment of fashion, or on a combination of these. I have not included it under paramount requirements, but it is nevertheless the crowning element of an edifice in its relations with the contemporary public and with posterity and history." And I will say upon this head only this, that the general proportions in materials of construction of such a building as this justify a general simplicity and demand the utmost dignity of treatment. This simplicity should, however, not become baldness, nor should the poetic element be excluded from the design.

* Paper by D. Adler, read at Annual Convention of American Institute of Architects, Chicago, October, 1887.

THE MILWAUKEE DRAW-BRIDGE.

THE 205-foot span double-track draw-bridge at Milwaukee was designed and built for the Chicago, Milwaukee and St. Paul Railroad by the Edgemoor Iron Co. While having neither extraordinary features nor unusual span, it is an example of carefully-finished design and excellent arrangement in most recent practice.

The link connection at centre of top chord secures perfect equalization of strains in centre posts under all conditions of loading and position, and the transmission of load to the drum at the four points of intersection with cross-girders precludes any ambiguity of strains and permits unusual compactness and simplicity of turning gear. The draw is swung by a steam-engine geared directly to shaft E (see Fig. 3), which, through the idler I, engages shaft C in the required horizontal position, and through the bevel gear N drives the main shaft A, made in two sections, whose pinions at each end engage the bevelled wheels H H. H is keyed to a sleeve, loose on shaft G, but engaging at will a clutch sleeve, S, revolving with G. When the clutch engages, as shown in figure, G, by its pinion J, drives L, whose vertical shaft carries the driving pinion P, that works on the stationary curved rack R.

If for any reason the steam-power fails it is quickly disconnected by dropping handle *a* of the sleeve-lever, which releases clutch S.

If hand-power be required only temporarily a capstan-head can be placed on shaft G. This will require the strength of several men, and if hand-power is needed for any length of time the auxiliary gearing L', with capstan-head Q, is conveniently swung into position, and when secured in place provides a train suitably geared for operation by two men.

When closed the draw is secured by spring-latch X and to swing the attendant must just release it by partly turning shaft Z, whose pinion operates racks O O, each of which pulls latch-rod M, compresses spring Y, and withdraws bolt X. The turning gear may now commence to operate, and the attendant completes the stroke of the lever, turning Z. M, being pulled to its limit, draws the latch-tail U through the aperture in the end floor-beam until it is sufficiently depressed by guard V to lift the catch out of draw-loop W, and the spring Y being released throws the bolt out ready to lock when the bridge is swung to its seat.

No lifting-gear is provided or required, as the the ends rest on beveled shoe-plates that are forced by the turning mechanism to ride up on to their roller-seats and insure the intended bearing contact when the bridge is unloaded; the lower lateral system is proportioned to receive the impact and flexure from this strain.

The trusses are assumed to carry all pressure to centre pier, except when strained by live loads.

Each panel of top chord is lengthened $\frac{1}{4}$ -inch for camber. All truss members are wrought-iron, except the annealed steel eye-bars and steel chord-pins fitting holes up to 5 inches diameter within $\frac{1}{8}$ -inch, and holes above 5 inches within $\frac{1}{4}$ inch. The mill and shopwork, quality of material, etc., was according to standard bridge specifications of the Chicago, Milwaukee & St. Paul Railroad.

The structure was proportioned for a live load, on chords, of 2,600 pounds per foot of track over all, or 3,000 pounds per foot on one arm, for ties and posts, and two Mogul engines, followed by 3,000 pounds per foot of track; and the floor system for two Mogul engines, + 25 per cent. for floor beams and + 30 per cent for stringers for impact.

The shipping weight of trusses was 416,143 pounds; of castings and mechanism, 56,438 pounds; extras, 60,722 pounds; total metal weight of structure, 533,303 pounds.

TESTS OF THE WESTINGHOUSE AIR-BRAKE.

WE take great pleasure in noticing the tests of this apparatus made on the West Shore road at Ridgefield, N. J., on Monday last, for the reason that we believe it marks another long step towards absolute safety in handling railroad trains.

Mr. Westinghouse has been long working on the problem, and now expresses himself as satisfied that he has obtained a form of apparatus that is simple, easily managed, and durable.

The special train arranged for these tests consists of fifty freight cars, each of 60,000 pounds capacity and weighing about fifteen tons.

The portion of track selected had a down grade of 53 feet to the mile, and the tests and results were as follows, all tests being made on the down grade:

First, an emergency stop from a speed of 23 miles an hour. The time occupied, $12\frac{1}{4}$ seconds, and space traveled, 203 feet.

Second, the same from a speed of 41 miles an hour, accomplished in $19\frac{3}{4}$ seconds, and 674 $\frac{1}{2}$ feet distance.

Third, a test of quickness of application. In this test the whistle was heard announcing the application of the brake, and the brake was in full action at the end of the train at practically the same instant. In other words, the impulse applying the brakes and the sound-wave through the air traveled at the same speed. Mr. Westinghouse says the speed has been determined as about 1,000 feet per second, or $1\frac{1}{2}$ seconds through the fifty-car train. They had succeeded in reducing this one-eighth of a second, but the reduction did not compensate for difficulties in other directions. The air-pipes are increased one quarter inch in diameter, or to an inch and a quarter in the new apparatus.

The fourth test was an emergency stop from 41 miles per hour, to show passengers on board the effect of quick stopping. This was accomplished in 20 seconds, and 672 $\frac{1}{2}$ feet.

The fifth test was to show the time required to release the brakes after stopping and getting the train in motion again. This was $4\frac{1}{4}$ seconds.

The sixth test was by hand brakes alone with five brakemen. This required 84 seconds, and a travel of 2,137 feet. Of course had the locomotive brake been applied also the distance would have been greatly reduced.

Seventh test.—In this the train was broken in two when at a speed of 25 miles per hour, and both portions stopped with an intervening distance of 43 feet.

Eighth test.—An emergency stop from 22 miles, with 20 cars to represent an ordinary passenger train, all available means of stopping being used. This was accomplished in six seconds, with a travel of 91 feet.

The ninth test on the programme was omitted on account of the lateness of the hour.

The tenth test consisted of the 20-car train on one track, and a train of ten heavy passenger cars (about 18 tons each) on the adjoining track, the latter fitted with the ordinary Westinghouse brake.

The speed acquired at the point where the brakes were applied was 45 miles. The 20-car train stopped in $13\frac{1}{2}$ seconds after running 495 feet. The passenger train ran 1,204 feet before stopping.

Such exhibitions cannot help resulting in great good, since they bring the brake so prominently before all who are interested in such matters in the locality where they are made; and we were glad to know that railroad men, professors, students, and capitalists were fully represented among the observers.

LONDON CORRESPONDENCE.

Austrian Bridge Construction Regulations—International Exhibition of Fire-Extinguishing Apparatus at Paris—Anglo-American Brush Electric-Light Company in London.

RAILWAY engineers will be interested to note the new regulations issued by the Ministry of Commerce at Vienna with regard to the building of railway bridges in the future. Briefly stated, these are, that constructive engineers of bridges with a span of sixty-six feet or more will have to file plans and full particulars respecting foundations, piers, girders, weight, rolling load, strain, and limit of deformation. Tabular matter has been prepared by the ministry averaging the span and weight of the bridge with regard to loads.

AN "International" Exhibition is announced to be held from the 25th inst. in the Municipal Pavilion of the Champs Elysées, Paris, which, in the present state of public feeling, will doubtless prove a success. The object of the exhibition is to exhibit fire extinguishing and preventing apparatus, and it is announced that there will be theatrical performances with sham fires introduced.

THE Anglo-American Brush Electric-Light Corporation are again about to try the experiment of introducing the electric light into the city of London. They have obtained the consent of the City Corporation to lay a main over Blackfriars' Bridge into the city, the City Corporation stipulating that the company shall supply householders on the route at the same price as that charged for the city. As a new electric-lighting bill, doing away with the stringent "old iron clause" in the old one, will doubtless be passed in the course of the next year or two, the A. A. B. Co. evidently anticipate more favorable opportunities to do business.

THE GIRARD COLLEGE ROOF.

(Correspondence.)

PHILADELPHIA, November 22.

CONSIDERABLE excitement was caused in the building circles of Philadelphia by the announcement that the marble roof of the Girard College building was leaking and was about to be covered with tin. Investigation proves the report to be true. The architect in charge of the works of the Girard Trust, Mr. James H. Windrim, says that by the action of the water and the fumes of bituminous coal the marble roof of this great building has become disintegrated and soft, and in consequence of this the rain has been running through. At a meeting of the Girard Trust the project of replacing the roof with a marble one was discussed, but as it would cost some \$150,000 and a tin one but about \$10,000, it was determined to use the latter. The marble-work now forming the roof will not be removed, but in the spring a roofing of sheet-tin will be put over the boarding now in place.

EIGHTY-FIFTH ANNUAL REPORT OF THE PHILADELPHIA WATER DEPARTMENT.

THIS complete and exhaustive report begins with that of the Chief Engineer, Mr. John L. Ogden, the remainder of the volume being made up of appendices by the Registrar, Mr. A. N. Heithler; by the Chief Clerk, Mr. J. T. Hickman; by the General Superintendent, Mr. F. L. Hand; by Assistant Engineer, Mr. Allen J. Fuller; by Mr. W. F. Courtney, Shop Superintendent; by Mr. John E. Codman, Chief Draughtsman; by Assistant Engineer, Mr. Amasa Ely, on Hydrographic Work; by Mr. Rudolph Hering, Engineer in charge of Surveys for new supply; and addresses by Drs. Charles W. Dulles and J. Cheston Morris on Water-Supply.

The total receipts for the year ending February 1 were nearly \$2,000,000, being an increase of $5\frac{1}{2}$ per cent. on the previous year.

Deducting special appropriation of about \$565,000 for extensions, the excess over expenses was \$1,368,000.

The least amount of water pumped per day was 49,187,598 gallons in February; the greatest 102,202,857 in July, and the average 78,433,289. The increase in amount pumped for this over the preceding year was about 14 per cent.

Of the total supply about 90 $\frac{1}{2}$ per cent. is from the Schuylkill, about 7 per cent. from the Delaware, and the remainder from springs at Chestnut Hill. That from the Delaware at Otis Street is through a conduit reaching 200 feet beyond the wharf and 34 feet below low water.

The population has increased from 795,000 in 1877 to 975,000 in 1886, or nearly 23 per cent., while the consumption per capita has increased from 61 gallons to 80 gallons, or over 31 per cent.

Of the total pumpage, about 25 per cent. is by water-power and the remainder by steam. The cost, including repairs, was \$2.09 per million gallons raised 100 feet by water, and \$4.48 by steam, or \$4.13 for the total pumped.

The actual cost, including running expenses of stations, was \$6.66 per million gallons raised into the reservoirs, or, including the total expense of the department, \$14.59. If to this interest at six per cent. on \$15,000,000 (value of plant) be added, the cost per million gallons would be \$46.

The revenue of the department for the year was \$61.86 per million gallons, showing that it is advisable to reduce the rates, especially to manufacturers.

The 36-inch submerged main across the Schuylkill, laid many years ago, having Ward's patent joints, needs renewing.

The East Park Reservoir, on which work ceased twelve years ago, it is recommended should be completed. This will add 701 millions to the storage capacity. That this is necessary is shown by the fact that the storage available for no part of the city exceeds eight days, and from this it varies for other parts to as low as two and a half days. About 185,000 persons are supplied by direct pumpage.

The experiment of purifying the water by aeration (forcing in air under pressure) was tried. Twenty per cent. of air by volume caused the almost complete disappearance of free ammonia, and the destruction of one-half the albuminoid ammonia. The difficulty was a great increase in leaky joints, the leaks ceasing as soon as the air-compressors were stopped.

About 137,000 feet of extensions were made to the mains, which, with pipes relaid, made a larger amount than in any previous year. The total pipes in use now measure 853 miles.

A new compound Gaskill pumping-engine has been erected by the Holly Manufacturing Company, capable of supplying 20,000,000 gallons per day, with a guaranteed duty of 110,000,000, and at a cost of \$69,000. The seven boilers, costing \$26,965, by J. P. Morris & Co., are rated at 560 nominal horse-power.

Detailed tests of two of the boilers are given. They evaporated eleven pounds of water from and at 212° Fah. per pound of combustible, furnishing very dry steam, and developed forty-four horse-power more than they were rated at. Drawings are given of the boilers and settings in use.

The report shows that the minimum flow of the Schuylkill is 245,000,000 gallons per day—an amount sufficient to supply the city thirty years hence. Of this flow nearly two-thirds is now used in furnishing power for pumping. By inexpensive storage-reservoirs on the mountain streams this flow could be increased.

Mr. Ogden holds that the water of the Schuylkill is wholesome, but that it can and will be improved both in appearance and quality. The suggestion of filter-beds is made. The completion of the intercepting-sewer will aid in improving its quality.

Mr. Ogden thinks it well to select streams as a source of increase after the Schuylkill is fully utilized, so that their collecting areas may be purchased and turned into parks or forests and kept free from contamination.

Complaint is made of the increasing difficulty of laying large mains on account of the sewers, drains, gas-pipes, electric-conduits, etc. The cost in one case was increased 19 per cent. in consequence.

Mr. Ely describes and illustrates an automatic stream-gauge, and also the method pursued for gauging during freshets.

Mr. Hering's report is very full and complete, entering into a discussion of questions of topography, precipitation, stream-flow, storage-reservoirs, their capacity and cost per million gallons stored, and quality of water. Very full tables are given, specimens of maps and engravings of instruments used; also, curves of discharge, etc., etc.

It is seldom that an engineer has an opportunity of giving so much and such varied information in a single report.

THE ENGINEERS' CLUB OF ST. LOUIS.

The club met at Washington University, November 16, 1887, President Potter in the chair; W. H. Bryan, Secretary; thirty members and four visitors present. The following persons were elected to membership: A. C. Glasgow, R. F. Grady, J. A. Laird, Frank Nicholson, P. W. Schaumleffel, and J. P. Thul. After a discussion on a communication from the Board of Managers of the Association of Engineering Societies the following was adopted:

Resolved, That in the opinion of the Engineers' Club of St. Louis an attempt at an organic union is not desirable. We, therefore, decline to favor the recommendation of the Board of Managers.

The following committee on nominations of officers for the coming year was then elected: J. A. Seddon, chairman; R. E. McMath, S. B. Russell, E. A. Engler, J. A. Ockerson. Professor Johnson then read a paper on "Testing the Strength of Engineering Materials," in the course of which he said that to load a member slightly beyond its elastic limit did not necessarily injure it; in fact, to thus "take the stretch out of it" might even benefit it for some purposes. Mr. Nipher exhibited a cast-iron cup which had been attached to the bottom of a piece of wrought-iron pipe filled with water, and broken by firing a rifle ball from above into the water.

WIDENING THE NIAGARA FALLS AND CLIFTON SUSPENSION BRIDGE.

WE take the following from a communication received from Mr. M. Harrington, Superintendent of the Bridge:

"The first cable for the structure was carried over in the spring of 1865, on the ice bridge, and the structure completed in the winter of 1868. It was publicly opened on January 2.

"Many changes have been made since in the appearance of the bridge. The original towers were of heavy framed timbers, exposed to view, but afterwards covered with corrugated iron. In 1884 these gave way to the present handsome iron towers. The present Superintendent, shortly after his appointment, a few years ago, made a thorough inspection of the anchor pits, anchorages, etc., the first that had been made since the bridge was built, and found everything as perfect as when the bridge was first put in position.

"Plans have recently been adopted for increasing the width of the bridge, and in accomplishing the work it will be necessary to practically rebuild the entire structure, except the towers. This will not, however, interfere with travel across the structure.

"The present anchor-plates on the New York side are 18 feet below the surface of the ground; the new plates will be 50 feet below the surface, 26 of which will be in solid rock. Each anchorage shaft plan will be 7x3 feet and 26 feet in depth, at which point the anchor plate will be set. It is a casting 5 feet 6 inches square by 32 inches in depth, chambered out to secure the anchor-bars, which are 14 in number, $\frac{3}{8}$ x6 inches. From this point the number of bars are gradually increased to the point where connections are made to the cables, and will terminate in 28 bars giving a sectional area of 125 square inches, equal to a bar about 11 inches square of solid iron. The cables are composed of galvanized steel wire-ropes $2\frac{1}{4}$ inches in diameter, seven of these ropes forming one cable, each rope having a separate fastening to the before-mentioned anchor-bars. There will be one pair of cables on each side of the bridge seven inches in diameter, or four cables in all. On the Canadian side the anchorages will be similar, except that the anchor-plates will be set 36 feet below the surface of the earth, owing to the fact that the rock comes to the surface of the earth at that point.

"The present cables are amply competent to carry the additional load of the widened bridge. They are of first-class charcoal iron, but as the moduli of elasticity of steel and iron are not the same it is impossible to equitably divide the load between the two sets of cables of different materials necessitating the abandoning of the present cables for steel ones. The road-bed when completed will have a clear width of sixteen feet, the present being only ten feet. The present suspenders by which the bridge proper is held to the cables are of $\frac{3}{8}$ wire rope, for which $\frac{3}{4}$ wire rope will be substituted. The present truss system of six feet in depth will be changed to iron of twelve feet in depth, and all transverse beams will be of plate and angle iron, the flooring being secured to rolled I-beams. The system of overhead stays will be abandoned, owing to the change made in the depth of the truss. It is the intention to abandon the river guys, substituting therefor a lateral wind cable system that will far more effectually perform the service imposed upon the river guys, and thus do away with the damage incident to them by floating ice and falling rocks, which has been an expense of no small amount.

"The work will be done under the personal supervision of G. W. McNulty, of the firm of Buck & McNulty, Civil Engineers, of New York. The iron will be furnished by the Rochester Bridge Works, and the wire ropes will be supplied by the John A. Roebling's Sons Co., of Trenton. The work of excavation will be done by Messrs. Phillips & Young, of Niagara Falls, who began work the last of August. The work of stringing the cables has been commenced. The contracts require the completion of the work by the 15th of April next."

WESTERN ASSOCIATION OF ARCHITECTS.

AMONG those present at the Annual Convention of the Western Association of Architects at Cincinnati last week were the following gentlemen:

D. Adler, Chicago; Henry Lord Gay, editor *Building Budget*, Chicago; James F. Alexander, Lafayette, Ind.; James E. Wolfe, editor *California Architect and Building News*, San Francisco; Charles E. Hellmers, St. Louis; Charles Crapsey, Cincinnati; E. A. Wells, Wheeling, W. Va.; George W. Cramer, Akron, O.; J. M. Freese, Columbus, O.; E. Anderson, Cincinnati; H. M. Parker, Coldwater, Mich.; J. A. Treat, Chicago; Louis Sullivan, Chicago; H. A. Linthwaite, Columbus; J. W. Taylor, Chicago; Guy Tilden, Canton, O.; George W. Thompson, Nashville, Tenn.; John Sutcliffe, Birmingham, Ala.; John M. Root, Chicago; Clarence O. Arey, Cleveland; W. W. Carlin, Buffalo, N. Y.; Paul C. Lathrop, Chicago; J. W. Yost, Columbus, O.; A. E. Siter, Cincinnati; W. S. Matthews, Kansas City; R. C. Berlin, Chicago; A. Y. C. Clas, Milwaukee; L. J. Schaub, Chicago; Howland Russell, Milwaukee, Wis.; F. S. Allen, Joliet, Ill.; E. O. Elzner, Cincinnati; Normand S. Patton, Chicago; Sidney Smith, Omaha, Neb.; Frederick Bauman, Chicago; Oscar Cobb, Chicago; J. J. Flanders, Chicago; F. G. Cowen, Minneapolis, Minn.; R. A. McLean, Chicago; H. C. Lindsay, Zanesville, O.; Bernard Vonnegut, Indianapolis; Cyrus K. Porter, Charles K. Percival, Jesse R. Porter, Buffalo, N. Y.; John K. Allen, the *Sanitary News*, Chicago; William K. Aiken, Cincinnati; S. H. Maetzel, Columbus; George L. Fisher, Omaha, Neb.; Albert B. Baumann, J. F. Baumann, Knoxville, Tenn.; Walter R. Forbush, Cincinnati; George J. Fickes, Steubenville, O.; Gustav W. Drach, George W. Rapp, Cincinnati; William Nier, Kansas City; T. Fitzhugh, Cincinnati; Emil G. Rueckert, Cincinnati; Max Reutti, Hamilton, O.; Charles E. Baldwin, Minneapolis; Frank J. Otter, Dayton, O.; C. C. Burke, Memphis; W. R. Brown, Cincinnati; Curtin, Louisville, Ky.; James W. McLaughlin, Cincinnati.

FRANKLIN, MASS., WAS REFERRED TO.

CINCINNATI, November 23, 1887.

SIR: In your issue of 19th inst. under head of "Lessons From Recent Water-Works Disasters," among other places mentioned, you speak of the fall of the Franklin Water-Tower.

As there are several Franklins in the United States, and as I happen at the present time to be engaged as the engineer constructing the Franklin, O., Water-Works, where the service is direct, with no water-tower or stand-pipe, will you kindly state that the Franklin you mean is not my Franklin, to avoid a possible false impression taking root among your readers in this part of the country? Your remarks upon this topic receive my hearty commendation. Very respectfully yours,

JOHN W. HILL,
Consulting Engineer, Franklin, O., W. W.

REGISTRATION OF VITAL STATISTICS IN NEW YORK STATE.

FROM the report of Dr. Balch, the Secretary of the State Board of Health of New York, for the first half of 1887, we learn that the registration of vital statistics in the State is becoming more complete and accurate. Forty-eight thousand deaths were reported in the State during the half year, being over 3,000 more than the number reported in 1886, and 10,000 more than in 1885. The health of the State has been remarkably good, and this increase in the number of deaths reported is due entirely to the fact that the returns are more complete. The true mortality-rate of the State for the first six months of this year was probably about 18 per 1,000. Diphtheria caused a larger number of deaths than any other zymotic disease, nearly one-fourth of the preventable diseases being from this cause. About 62.5 per 1,000 of the total was from diphtheria. About one-eighth of the zymotic mortality was from measles. Scarlet fever was epidemic in smaller localities, about 100 deaths a month having pretty constantly occurred thus far this year. Cerebro-spinal fever has occurred very uniformly month after month. There were about 300 deaths from January to July. Troy reports a large proportion of the deaths, and they occur, not spasmodically, but constantly. The central and western counties are quite free from it. Only one case of typhus fever, and that from Brooklyn, is reported. From small-pox 127 deaths, twice as many as in 1885 and 1886, were reported. Most of these occurred in New York and Brooklyn, three deaths occurring in Albany, the origin of which was traced to Brooklyn. There were 6,800 deaths from acute respiratory diseases, and from consumption 6,827, or about 130 per 1,000. In 1885 there were 140 deaths and in 1886 138 per 1,000.

WE quote from a recent number of the *Electrician* the following French specification filed by La Société pour la Transport de la Force par l'Electricité, for a method of lighting railroad cars by electricity. The proposal is to place a small windmill on the roof of each car, and so provide power for the dynamos, secondary batteries and lamps. The *Electrician*, commenting on the above, says, that while it hopes for the best, yet they are prepared—fully prepared—for the worst.

PERSONAL.

COLONEL C. B. PENROSE, U. S. A., left St. Paul last week for Fort Leavenworth, Kan., his new station.

CAPTAIN L. E. CAMPBELL, U. S. A., left Fort Leavenworth a few days ago for Denver, Col., where he will hereafter be located.

PROF. S. P. LANGLEY, has been elected by the Regents of the Smithsonian Institution, to the position left vacant by the death of Prof. S. F. Baird.

DR. JOHN S. BILLINGS, Surgeon U. S. A., of Washington, D. C., has been elected President of the Congress of American Physicians and Surgeons which is to meet in Washington next September.

GOVERNOR HILL has appointed Mrs. Charlotte S. Williams, of Buffalo, and Mrs. Caroline B. Stoddard, of Rochester, to fill the vacancies in the Board of Managers for the State Insane Asylum at Buffalo, N. Y.

ENGINEER THOMAS J. WHITMAN, of St. Louis, has entered upon his duties of investigation in connection with the sewerage problem in Milwaukee. Draughtsmen and clerks necessary to do the detail work in connection with the investigation will be employed.

THEODORE R. VARICK, M. D., President of the Hudson County, N. J., Board of Health, Director of the State Asylum for Insane at Morris Plains, and a member of New York Academy of Medicine, died at Jersey City, November 23, aged sixty-one.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITIONS.

COURT-HOUSE.—Plans for Court-House wanted, until December 5, by James P. Coffin, Commissioner of Public Buildings, Powhatan, Lawrence County, Ark.

FORT WAYNE, IND.—Plans and specifications for a new city hall to cost about \$60,000. Building to be 50x140 feet and to contain accommodations for all the city officers, a council chamber, also a police prison and office, with accommodations for four horses and two patrol wagons. Until December 6, address Charles F. Muhler, of the Special Building Committee of the Common Council.

For works for which proposals are requested see also the "Proposal Column," pages 729-732-733-736-751.

Persons who make any use of the information they find in these columns we trust will not omit to mention THE ENGINEERING & BUILDING RECORD as the source.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." Information of importance sent to us exclusively, and not elsewhere published, will be liberally paid for.

WATER. SEWERAGE, ETC.

TUSCALOOSA, ALA.—This city has closed a contract with Jeter & Boardman, of Macon, Ga., for a complete system of water-works.

PONTIAC, MICH.—Proposals are wanted for water-works here. Address, until December 21, F. B. Galbraith, Mayor.

CENTRAL CITY, KY.—Water-works are contemplated and will probably be built soon. The Central Coal and Iron Co. can give particulars.

MARBLE FALLS, TEX.—J. J. M. Smith, of this place, wants to correspond with manufacturers of water-works supplies.

WINCHENDON, MASS.—Our correspondent writes: "A committee has been chosen to investigate the subject of water-works and make surveys and report at the annual meeting in March, 1888."

MILWAUKEE, WIS.—Messrs. Gray Brothers write: "We have contract for boring a well at West De Pere, Wis., and until that is finished they will do nothing in regard to mains or hydrants. Their intention is to supply the town with water."

PENSACOLA, FLA.—Our correspondent writes: "This municipality has adopted the Waring system, which will cost about \$90,000 when completed. Expect to commence work in December."

WESTERVILLE, O.—Concerning a report that water-works were to be built here, our correspondent writes as follows: "There has been no steps taken for water-works officially. There has been some talk by citizens, but nothing more."

JACKSONVILLE, ILL.—Our correspondent writes: "The following was passed by the City Council Tuesday evening, November 15: 'Resolved, That the Board of Water Commissioners be instructed to advertise for proposals to furnish the city with one or more million gallons of water every twenty-four hours. All propositions to be submitted to the council for their approval or rejection.'"

KINSLEY, KAN.—The contract for the water-works has been awarded to D. Mitchell & Co., of Dodge City, Kan., who will have the system in operation during January. There will be pumping-engines with a daily capacity of 750,000 gallons, four miles of mains and a stand-pipe.

LAKE LINDEN, MICH.—Our correspondent writes: "We have just completed a system of water-works, 85 pounds gravity pressure. The system cost about \$40,000, and for fire protection is equal to the best, the supply being all that could be desired."

RAHWAY, N. J.—The contract between the Pennsylvania Railroad Co. and the Water Board, which the company recently refused to renew because of increase of rates, has been renewed at old rates, \$4,000 per annum, with privilege of either party upon thirty days' notice ending the same.

COLUMBUS, NEB.—The contract for an additional steam-pump and boiler has been awarded to Charles Schroeder, the contractor for the works, at \$2,150.

COSHOCOTON, O.—The contract for the water-works has been awarded to the American Water Works & Guarantee Co., of Pittsburgh, Pa. The company will have the system in operation by January.

KENDALLVILLE, IND.—Contracts have been awarded to the Knowles Steam Pump Works, of New York City, for pumps; to R. D. Wood & Co., of Philadelphia, Pa., for pipe and hydrants; and to James Flower & Bro., Detroit, Mich., for valves.

DOVER, N. H.—The citizens will settle the question of building water-works by a vote at an early day. The cost of the project now contemplated is \$280,000.

NORFOLK, VA.—An improved system of water-works will probably be established here shortly, as the present system is deemed insufficient. At a recent meeting of the Common Council, Mr. John R. Todd, registrar of the Water-Department, submitted three propositions for furnishing the city with water. The matter was referred to the Water Committee for immediate investigation. Mr. Todd can give full information.

PENSACOLA, FLA.—The Board of Health have appropriated \$15,000 to construct the sewerage system. The Mayor can give information.

OCALA, FLA.—Water-works are to be erected here at once.

JOLIET, ILL.—This city wants proposals for water-works, until January 1. Address John D. Paige, Mayor.

SHERMAN, TEX.—This city has made a contract with E. Sutphin for a daily supply of 1,000,000 gallons of water for \$33,000.

COLUMBUS, O.—The Sanitary Committee has been instructed to enter into correspondence with sanitary engineers with a view of securing a suitable opinion as soon as possible concerning the defects in their sewerage system.

SEABRIGHT, N. J.—A stock company will probably be formed here to supply residents with artesian water.

SANDUSKY, OHIO.—The city will vote on a proposition to issue \$32,000 in bonds for a new pumping engine for the water-works.

KEY WEST, FLA.—Our correspondent says: "We are in communication with George E. Waring, Jr., Esq., and will probably secure his services to give us a plan and estimate for a system of sanitary engineering."

GREENVILLE, TEX.—Our correspondent says: "City had contract with M. P. Kelly and J. R. Williams (former of Corsicana, Tex., latter of St. Louis) to put in water-works, same to be completed by November 1, 1887. They purchased ground for plant, but did nothing more, and hence forfeited their franchise and bond for construction. Suit is ordered to be instituted on bond. No bids are being considered at present, though city is very anxious for a plant to be put in. Compress with 3,000 bales cotton burned three days ago here. No bids are now before the Council."

PHILADELPHIA, PA.—The first of the new subsidizing reservoirs, known as the East Park Reservoir, was put in use November 21. The Mayor will ask for appropriations next year to complete two more sections, which, when finished, will have a total capacity of 750,000,000 gallons.

AUSTIN, ILL.—Our correspondent writes: "The Cicero Water, Gas and Electric Light Company has bought the Scoville plant at Oak Park and now proposes to supply a territory contiguous to Chicago (on the west) with a No. 1 artesian water; said territory is 3x5 miles."

MANITOWOC, WIS.—Our correspondent says: "The Board of Aldermen of this city has granted a water-works franchise to Moffett, Hodgkins & Clarke, of Watertown, N. Y., for 20 years. System contains 12.3 miles of pipe, 6-inch to 16-inch, and 132 hydrants. Annual rental, \$6,500; two pumps of 1,500,000 gallons each. Water is to be taken from filtering galleries on shore of Lake Michigan, which experiments have proved most clear and wholesome, and which will undoubtedly result in a large number of water-takers. Work will commence early in the spring."

TOPEKA, KAN.—The Topeka Land and Water Power Company submitted a proposition to the Council to vote \$150,000 in 5 per cent. 20 years' bonds to aid in the construction of a dam, and rent power. The Council fixed December 6, 1887, as the day of election to submit the proposition to the people.

GENEVA, N. Y.—Our correspondent writes: "The Worthington pump and boiler for same have been delivered at this station on the lake shore. The building is nearly completed, and the contractor is building a coffer-dam 600 feet into the lake for the supply-pipe; the force main is all completed."

SUPERIOR, NEB.—Our correspondent says: "The city of Superior has only arranged to receive bids or estimates for water-works. There is to be a franchise granted in case the plans and specifications are satisfactory."

ST. SAUVEUR, CAN., P. Q.—Our correspondent says: "Our water-works is yet in contemplation; no decisions have been determined; so far we have only asked for plans and best means of construction."

THOMASVILLE, GA.—Bids for the following water-works supplies will be received by the undersigned up to November 30: Water-pipe, 2,500 feet each of 8-inch, 6-inch, and 4-inch, 100 feet of 3-inch; gates, two 8-inch, five 6-inch, four 4-inch, two 3-inch; 20 double-nozzle fire-hydrants, 13 stop-gate extension boxes, etc. A. F. Prevatt, Thomasville, Ga.

NEW YORK CITY.—The project for taking water from the mountain brooks in the town of Warwick and the various ravines and watersheds of the Ramapo Mountains, for use in supplying this city and Brooklyn, has been pushed forward steadily during the past season. Maps for the various reservoirs, pipe-lines, rights of ways, etc., which will be needed to carry it out, have been filed in the Clerks' Offices of Orange, Rockland, and other counties, the system would pass through. It is believed that the scheme will in a few months take a definite shape and the coming season may see active operations on foot by a strong corporation. The head of all the system as proposed will be in the valley of the Long House Creek.

MONTREAL, CAN.—The Lawrence Machine Company, of Lawrence, Mass., have been awarded a contract for a pumping-plant in this city. The plant consists of four centrifugal pumps, each of which is capable of conveying 18,000 gallons of water per minute, and four smaller pumps that are each able to discharge 7,000 gallons per minute. The large pumps can thus take care of 72,000 per minute, 4,320,000 per hour, 103,680,000, or 366,000 tons of water per day, and the small pumps would remove 28,000 per minute, or 1,680,000 per hour. The pumps are intended to drive the sewage of the city over the walls and dikes which are now being erected in the lower part of the city to protect it from big freshets.

ULYSSES, KAN.—Our correspondent writes: "Water-works company just incorporated. Will not commence work until next summer at least."

HAYWARD, WIS.—Our correspondent writes: "We are putting in the water-works now and are soon to be completed."

ST. LOUIS, MO.—Our correspondent writes: "Negotiations in progress for purchasing site for pumping works and intake from river at Chain of Rocks. Bill to provide for employment of the necessary engineers, inspectors, etc., introduced in House of Delegates, November 15."

PLYMOUTH, O.—Our correspondent writes: "There has nothing definite been done in regard to any water-works in our place."

TREMSEH, MICH.—In reference to a report that an improved water-works system was to be built here, our correspondent writes: "The township is taking no steps in that direction. The village has small water-works, but are not talking of anything more. Have just been erecting a tank at a cost of \$2,500."

ALBERT LEA, MINN.—Our correspondent writes: "The matter of water-works has just been brought before the Council for consideration and the system is to be the direct-pressure—'Holly.' The formation of a company, securing a franchise, establishing the number of miles of mains and sub-mains, and the agreement of price the city is to pay for hydrants is yet to be decided. No immediate action is deemed advisable by Council, but the inclination is to accept the plan of paying a rental to a company rather than issue bonds. An artesian well, 217 feet deep, has been tested and analyzed, proving water first quality for household purposes—not quite soft—and of abundant supply."

PASSAIC, N. J.—It is probable that this city will soon make a movement towards a better sewerage system. The question is being agitated by officials and citizens.

CARLYLE, ILL.—The water-works erected for this city by the Water, Light, and Power Company, of St. Louis, still remains unaccepted by the City Council. The plant is said to be incomplete and not in accordance with the specifications of the contract. At the recent test of the works with stand-pipe and pump pressure at four points the water failed to reach the required height at one point, on account of 4-inch mains being used in that part of the city. With 4-inch mains water is forced 115 feet high. The company may be compelled to replace the 6-inch mains with 6-inch pipes before the works will be accepted by the Council.

WINDOM, KAN.—Our correspondent writes: "Our bonds of eight thousand dollars, for a system of water-works, carried by a large majority. We have abundance of water about two miles north of town, but the method of getting it here has not been decided upon. The board is ready to entertain propositions for this purpose."

CHICAGO, ILL.—The contract was executed November 19, between this city and Andrew Onderdonk, of New York, for the construction of the new water-works tunnel under the lake. The work will cost \$748,000, and the contractor gave a bond for \$500,000. The new tunnel is to be eight feet in diameter, and will extend from the south side lake front a distance of four miles into the lake.

COLUMBUS, O.—At a recent meeting of the Water-Works Trustees, a resolution was adopted to do away with the bids for a 15,000,000-gallon pumping-engine, which were received November 1, 1887, as they did not comply with the requirements of the advertisement for the same, and the superintendent was instructed to prepare specifications and readvertise for new bids to be submitted to the board at an early date.

VALLEY FALLS, KAN.—The contract for the water-works has been awarded to the U. S. Wind Engine & Pump Co., of Batavia, Ill., at \$14,778.

ALTOONA, PA.—Our correspondent writes: "The present reservoir embankment is being raised so as to impound 40,000,000 gallons more. Surveys have been made to several sources and estimates of cost which matter is now before the city council and will be referred to the Water Commissioners for recommendations."

GAYLORD, MICH.—Our correspondent writes: "This place voted November 15, to put in regular system of water-works."

PRINCETON, ILL.—Our correspondent writes: "The City Council has appropriated \$5,000 for an artesian well. The contract has just been awarded to J. P. Miller, of Chicago. Work will probably be commenced in ten days."

SOUTH FRAMINGHAM, MASS.—The question of a sewerage system is being agitated here. Developments are expected soon.

LANSINGBURG, N. Y.—1,000 feet of water-pipe will be laid here. Proposals will soon be wanted.

DUBUQUE, IOWA.—Our correspondent writes: "Franchises at Baton Rouge, La., was extended to Smedley & Wood, for 30 years; city has privilege of buying in 20 years; works exempt from taxation 15 years. There will be 2 one-million compound duplex pumping engines (Smedley manufacture), steel stand pipe, 6 miles of pipe from 12 to 4-inch; standard weights, 75 fire hydrants. City to pay \$45,000 a year rental for 75 hydrants."

MARIANNA, ARK.—Our correspondent writes: "The city contracted with the Fairbank Co. for a wind-mill and a tank of about 1,000 barrels capacity, but the company afterward refused to comply with their contract. Hence, the matter stands as before—open for propositions."

BRIDGES.

TOLEDO, O.—Our correspondent writes: "All surveys and location have been made by the Wheeling and Harrisburg Railway Company, and plans have been approved by the Secretary of War for a railway bridge over the Ohio River between Wheeling, W. Va., and Martin's Ferry, Ohio, at the head of Wheeling Island. It is expected that construction will begin in the early spring. The bridge will be 2,100 feet long, 90 feet above low water, with two deck spans 125' each, one through-span of 125', one of 130', one of 535' and four of 265' each."

SIoux CITY, IOWA.—The contract for the Iowa approach to the railway bridge for the Chicago & Northwestern Railroad across the Missouri River has been awarded to W. C. McNamara, of this city.

GOLIAH, TEXAS.—The following proposals for a bridge across the San Antonio River have been received at this city: Kansas City Bridge and Iron Company, Kansas City, Mo., \$11,500; Missouri Valley Bridge and Iron Works, Leavenworth, Kan., \$12,540; King Iron Bridge and Manufacturing Company, Cleveland, Ohio, \$12,500. The contract was awarded to the Kansas City company. The bridge will be a wrought-iron, double intersection high truss bridge, 140 feet span, 18 feet roadway, on cylinder piers of 3/8-inch iron 4 feet diameter, filled with concrete.

MARYLAND.—The contract for the construction of the substructure of the iron bridge across the Patapsco River, has been awarded to David Leonard: Masonry, \$13.50 per perch; piles, \$7.50 each; timber, \$30 per 1,000 feet, B. M.; bolts, 6 cents per pound. The bridge will be 200 feet span and will cost \$11,000.

CHARLESTON, W. VA.—The Charleston Bridge Co. has been chartered to build a bridge across the Kanawha River by R. M. Carr and S. M. Snyder, of Charleston, and others. The capital stock is \$50,000.

ERIE, PA.—Hon. W. L. Scott writes us that the announcement in regard to the proposed bridge across the Youghieny River is premature, although he expects to build a bridge there some time next summer.

CANTON, O.—John Hahn has been awarded contract for the construction of a bridge at this place.

BOSTON, MASS.—The Boston and New York Railroad is about to begin the construction of a new short-line road between New York and Boston. Bridge contractors should address at once D. C. Linsley, Managing Director, 146 Broadway, New York.

SAN JOSE, CAL.—Concerning bridge matters at this place, our correspondent writes: "A bridge across the Los Gatos Creek is under way. Contract awarded to San Francisco Bridge Co.; price, \$5,450.

Also, a bridge across the Guadalupe River is under way. Contract awarded to San Francisco Bridge Co.; price, \$5,450.

PORTLAND, ORE.—In answer to an inquiry concerning a reported scheme to erect a bridge over the Columbia River by the Columbia Bridge Company, our correspondent writes: "There is nothing being done at present. So far it is a project only."

DETROIT, MICH.—Our correspondent writes: "The city has contracted with the Milwaukee Bridge and Iron Works for constructing Belle Isle bridge for the sum of \$295,000, and the contractors are now getting out the timber preparatory to building the approaches thereto, also the stone for the substructure."

CALAIS, ME.—The contract for the construction of a bridge here has been awarded to the King Iron Bridge Company, of Cleveland, O.

BETHLEHEM, PA.—The Whisky Hill Bridge Co. will apply for a charter to erect a bridge over the Lehigh River in the County of Northampton.

ROCHESTER, N. Y.—In reply to an inquiry concerning bridge matters here, our correspondent writes: "The city is not engaged at present in the construction of any city bridges, although the subject of the construction of one or more is being agitated by the localities most interested."

COLUMBUS, NEB.—Our correspondent writes as follows: "Proposals are wanted for the construction of a bridge over Loup River, near this city. Until December 12, address John Stauffer, County Clerk, Columbus, Neb."

DETROIT, MICH.—In answer to an inquiry concerning the reported erection of new bridges over the railroad tracks at Fort Street, and at Lafayette Avenue, our correspondent writes as follows: "No steps have yet been taken towards the construction of the bridges mentioned."

NEW GLASGOW, N. S.—A report has recently been circulated that the people of this place contemplated building over the East River at Stellarton. Concerning such report our correspondent writes as follows: "No new bridges are contemplated in the place named, unless the Short Line Railway contemplates building one on their own account, which at present is highly improbable."

LINCOLN, NEB.—Concerning the erection of several bridges across the Platte River, our correspondent writes: "The bonds voted on November 8 failed to carry and no bridges will be built by the county very soon."

GAS AND ELECTRIC-LIGHTING.

LOWVILLE, N. Y.—The American Electric Light Co. will begin at once the erection of an electric-light plant here.

CHICAGO, ILL.—This city is agitating the question of placing additional electric lights along the river bank. Prof. Barrett has the project in hand.

DECATUR, ALA.—This place will shortly be lighted by gas.

BRISTOL, TENN.—H. H. Corson, representing the Thomson-Houston Electric-Light Co., of Boston, Mass., is negotiating for the erection of an electric-light plant for Bristol and Goodson, Va.

MANCHESTER, KY.—The Manchester Fuel, Power and Lighting Co. have asked for permit to build gas-works to cost from \$100,000 to \$150,000.

GLENDAL, O.—Alfred M. Allen will give details in relation to lighting the city for five years. Proposals are wanted.

ORANGE, MASS.—G. P. Warner has made a proposition to erect an electric-lighting plant here.

ANNISTON, ALA.—The Anniston Gas Co. has been organized, with a capital of \$25,000.

ARLINGTON, N. J.—The Thomson-Houston Electric-Light Co., 178 Devonshire Street, Boston, Mass., has been awarded the contract for the erection of an electric-light plant here.

ALTON, ILL.—The Gas Committee of the Council has reported in favor of the substitution of twenty electric street lights in place of others to be removed, and recommended that the contract be given to the electric-light company now holding the privilege. The report was adopted, and the committee empowered to make it.

BURTON, KAN.—This place has decided in favor of electric lights.

VANDALIA, ILL.—A 30-year franchise has been awarded to Messrs. George W. Brown and D. M. Clark to pipe the city and supply gas.

LEXINGTON, KY.—An ordinance directing the Mayor to contract with some one to bore for natural gas, with lease for ten years, has been passed by the Board of Aldermen.

HOOSICK FALLS, N. Y.—Messrs. Holmes, Lock & Hurd have been granted the franchise to erect and operate an electric-plant here. It will be completed by January 1.

KNOXVILLE, TENN.—The Knoxville Car-wheel Co. will erect an electric plant at their works.

LAREDO, TEX.—An electric-light plant is to be established here. A. L. McLane can give details.

ASHLAND, KY.—E. M. Roberts will establish an electric-light plant here.

NORRISTOWN, PA.—The Norristown Electric Light and Power Co. will make improvements.

OLEAN, N. Y.—The Olean Electric Light and Power Co. has been incorporated. Capital stock, \$25,000. W. M. Irish, G. V. Forman, and others, incorporators.

GOVERNUR, N. Y.—The American Illuminating and Power Co. has been incorporated. Capital stock, \$20,000. J. E. McAlaster, V. P. Abbott, E. D. Barry, and others, incorporators.

MILWAUKEE, WIS.—The Common Council has adopted resolutions authorizing a contract with the Badger Illuminating Company to erect and maintain electric lights at the intersection of certain streets. There are to be 30 lamps of 2,000 candle-power each. The contract is to extend from December 15, 1887, to December 5, 1890. The cost at present is to be \$150 per year. The city's contract with the Milwaukee Gas-Light Company does not expire until next June.

HASTINGS, MINN.—An electric-light plant is assured.

FARIBAULT, MINN.—Natural gas is discovered.

PHILADELPHIA, PA.—The Joint Committees of Councils on Finance and Gas met November 17, to consider a proposition to supply the city with 3,000,000 feet of gas annually in addition to the present capacity of the Philadelphia Gas-Works. No definite action was taken, though a proposition from a manufacturing company to build works at private expense on ground owned by the city was considered. It was stated that the prospective contractors were now furnishing water-gas to New York City and one or two other large cities by what is known as the "Flannery process." There was some opposition offered to immediate action, and the bill was laid over to be printed. It will be more fully considered at a special meeting to be called by the chair.

FREMONT, O.—The Fremont Electric Power Co. will erect a plant.

LOUISVILLE, KY.—The Brush Electric Co., of 328 W. Green Street, will increase their plant.

PITTSBURG, PA.—The contract for lighting the Hoosac Tunnel for the Fitchburg Railway Co. has been awarded to the Westinghouse Electric Co. of this city.

BRANDENBURG, KY.—The Rock Gas Co. will sink a well at once.

ROCKAWAY BEACH, L. I.—A franchise has been granted to Mr. Taylor, of this place, to erect an electric-light plant here.

PORTLAND, ME.—This place has contracted with the Consolidated Electric Light Company for 168 arc lights of 1200 candle-power, and 250 incandescent lights of thirty-two candle-power, for \$26,000 for one year.

STERLING, KAN.—The Sterling Electric Light and Power Company has accepted the proposition of the Archer Electric Manufacturing Company of Wichita, and the work of building and putting up the poles and wires will be begun as soon as possible.

OCALA, FLA.—An electric-lighting plant is to be established here at once.

ASHLAND, KY.—E. M. Roberts has made a proposition to light the city with electric lights. He contemplates erecting the plant.

JACKSONVILLE, FLA.—The Sub-Tropical Exposition Co. are negotiating for the erection of an electric-light plant.

CHATTANOOGA, TENN.—The Brush Electric-Light Company is now busy putting up the ten electric lights, permission for which was granted at the last session of the City Council.

NEW CORPORATIONS.—The Oakland, Cal., Electric Light and Motor Co.; capital stock, \$200,000; James Gamble, Piedmont; Andrew Baird, Berkeley; H. H. Watson, W. W. Blow and I. W. Corder, incorporators.—The Sturgis, Mich., Gas and Electric Light Co. Capital stock, \$120,000. Incorporators, F. B. Ainger and others.—The El Paso

Northwestern Railway and Telegraph Co., capital stock \$300,000, has been chartered to build a railroad about 25 miles long by H. L. Detweiler, Samuel Schultz, and others.—The Jenny Electric Light and Power Co. of Nashville, Tenn., has been incorporated by A. C. Green, W. H. Smith, and others.—The American Automatic Gas Lighting Co., of Portland, Me., has been incorporated; capital stock, \$500,000; Nathaniel H. Shaw, Somerville, Mass., and Hiram G. Farr, 75 Essex St., Boston, Mass., incorporators.—The St. Cloud Gas and Electric Light Co., of St. Cloud, Minn., has been incorporated; capital stock, \$100,000; D. H. Freeman, William Westerman, and others, incorporators.—The Metropolitan Street Lighting Co., of Cincinnati, O., has been incorporated; capital stock, \$50,000; William Glenn, Geo. Fewless, and others, incorporators.—The Sharpville Gas and Oil Co., of Sharpville, Neb., has been incorporated; capital stock, \$7,000.—The Mercer Gas and Fuel Co., of Piqua, O., has been incorporated; capital stock, \$700,000; Geo. H. Smeily, James B. Townsend, and others, incorporators.

STEAM-HEATING, BUILDINGS, ETC.

RALEIGH, N. C.—No contract has as yet been given out for putting heating apparatus in the State buildings. Hot-water or steam-heating will be used and as soon as a decision is made proposals will be made. The matter is in charge of Colonel W. J. Hicks, of this city.

RAILROADS, CANALS, ETC.

JERSEY CITY, N. J.—The Pennsylvania Railroad Co., will construct an elevated railway here, costing \$1,000,000. Address Chas. E. Pugh, General Manager, 233 South Fourth Street, Philadelphia, Pa., for further information.

BOSTON, MASS.—The Boston and New York Railroad announces that it is ready to let the contracts for constructing the new short-line road between New York and Boston. Address Wm. M. Thayer, Secretary, 8 Congress Street, Boston.

THE Third and Trumbull Street Railway Company at Elizabeth, N. J., has been incorporated. Directors elected: A. G. Keasby, Henry Conger, P. A. Van Doren, of Newark, and others.

BIDS OPENED.

BIRMINGHAM, ALA.—The contract for the construction of the water-works system has been awarded to Messrs. W. A. Jeter, of Macon, Ga., and J. M. Cobb, of Beloit.

TUSCALOOSA, ALA.—The contract for construction of water-works system for this place has been awarded to Messrs. Jeter & Boardman, of Macon, Ga.

ANNISTON, ALA.—The contract to erect the city building has been awarded H. H. Boddie.

CHARLESTON, W. VA.—The contract for the erection of the school-house here has been awarded to M. M. M. Buck at \$35,000.

AUBURN, N. Y.—The contract for the stone-work on the new Government building in this city has been awarded to Messrs. Sisson & Ocobock.

CHILLICOTHE, MO.—The contract for the erection of State Industrial Home has been awarded to Messrs. Parks & Glove at \$25,175.

SANTA FE, N. M.—The contract for the erection of Army Hospital at Fort Wingate has been awarded to Messrs. Dobson & Co.

ST. LOUIS, MO.—The Board of Public Improvements has awarded the King Iron Bridge and Manufacturing Company a contract to build the iron-work of the Grand Avenue Bridge across the Mill Creek Valley. The company will receive \$144,000 for the work. The contract requires that the work be completed within ten months.

SYNOPSIS of bids for pumps, engines, pipes, and buildings required for the North Minneapolis, Minn., water-works station, opened by the Committee on Water-Works, at Minneapolis, November 17, and reported by us last week:

Cincinnati-Newport Iron Pipe Company, 12,000 feet 36-inch cast-iron pipe, per ton, \$32.50; Shickle, Harrison & Howard, St. Louis, same amount of pipe, \$30.70; McNeal Pipe and Foundry Co., Burlington, N. J., \$30.69; Lake Shore Pipe Co., Cleveland, \$33; same company, one-half, \$29.70; R. D. Wood & Co., Philadelphia, \$30.50; Dennis Long & Co., Louisville, \$28.40.

Digitized by Google

ST. PAUL, MINN.—A new jobbing-house syndicate is being organized, with a capital stock of \$200,000. The company will invest \$22,000 in buildings.

MADISON, WIS.—The contract has been let for the erection of the passenger depot for the Chicago, Madison & Northern, to David Stephens, for \$11,000. This is exclusive of stone and brick, and will make the structure cost altogether about \$20,000.

Building Intelligence.

We solicit from each and every one of our readers information relating to projected buildings in their locality, and should be glad to receive newspaper clippings and other items of interest.

MISCELLANEOUS.

MILWAUKEE, WIS.—The county committee on insane asylum of the board of supervisors at a recent meeting decided to recommend the appropriation of \$60,000 to be used in erecting an addition to the Wauwatosa insane asylum.

CHICAGO, ILL.—A large \$60,000 hall will be erected at Noble & Blackhawk sts by Andrew Schultz; a, Theo. Lewandowski can give details.

OMAHA, NEB.—George Hammond can give details of large packing houses to be erected in this city soon.

WICHITA, KAN.—The plans for the main building of the Sisters' Academy in West Wichita will be submitted to the contractors in a few weeks.

HARRISON, NEB.—This town has voted to invest \$10,000 in a court-house and present it to Sioux County.

COLUMBIA CITY, IND.—Chauncey B. Mattoon will give particulars of the new court-house to be erected in this city.

ST. PAUL, MINN.—West St Paul is to have a school house which will be the largest in the city. It will cost \$50,000.

DAYTON, O.—No buildings over \$7,000 to report.

PROVIDENCE, R. I.—Nine permits have been issued for new buildings to cost less than \$7,000 each.

BALTIMORE, MD.—Cor Benson and Decatur, church; o, Ger Luth Church.

15 Stricker, near Tennant 3 story br bldg; o, C A Pindell.

CHICAGO, ILL.—The President of the Wisconsin Central Railway states that it is the intention of the company to expend about \$1,000,000 in the erection of depots in this city in the near future. The new depots, he says, will be after the English style of architecture.

CONCORD, N. H.—A Committee of the Trustees of the New Hampshire College of Agriculture and Mechanic Arts has voted to build and equip a building for instruction in mechanic arts at Hanover.

BUCKHANNON, W. VA.—A seminary to cost \$20,000 will be built. Rev L H Jordan can give details.

WARRENSBURG, MO.—This city will vote February 21 on a proposition to build a court-house to cost \$60,000.

PITTSFIELD, MASS.—St. Stephen's parish will build a new church on the site of the present edifice; Dr. Adams, Eugene Robbins and C. E. Merrill were appointed a committee to procure plans for a \$30,000 church.

KANSAS CITY.—417 Walnut, 3-story store; cost, \$20,000; o, Stranahan & Baker; a, H B Prudden; b, Geo. Youmans.

109 bldgs costing less than \$7,000.

PHILADELPHIA.—Woodland av, w 69th, hospital bldg.

Also 71 fr structures.

ALLEGHENY, PA.—The High School Committee of this city has decided to erect a new high school building. Major A. J. Pentecost is one of a committee on heating apparatus for the building, and James T. Steer is the architect. Bids will be asked for at once.

SUMMIT, N. J.—W H Deforest knows about a music-hall to be erected here.

LINCOLN, NEB.—Ed A Church can give information concerning an opera-house to be erected here; cost, \$100,000.

DECATUR, ALA.—Write to P J O'Brien, of Birmingham, for details of an opera-house to be erected in this city; cost, \$100,000.

SANTA FE, N. M.—Dobson & Co have been awarded the contract for the erection of the Army Hospital at Fort Wingate.

ST. PAUL, MINN.—The Central Presbyterian Church will build; outlay, \$60,000; R P Lewis, Gates R Johnson, and others, committee on plans.

OMAHA, NEB.—This city has voted issuance of \$200,000 in bonds for the purchase of eight school sites and the erection of five new buildings; also permission to build a \$50,000 addition to the High School and erect a new school building costing \$25,000.

CHATTANOOGA, TENN.—The Cincinnati Investment Co will erect 19 brick store-houses, at a cost of about \$100,000. W H Floyd has been engaged as architect and superintendent.

MARINETTE, WIS.—Work has been begun on Isaac Stephenson's mammoth new saw-mill on Tweedie Island, which will cost over \$150,000, and will have a daily capacity of 125,000 feet.

ST. PAUL, MINN.—View, near Juno, brick veneer church; cost, \$16,000; o, St James Parish.

Westminster, near Waverly, 25 to blk fr dwell; cost, \$10,000; o, J Smith.

25 minor permits, \$30,000.

PORTLAND, ORE.—The Willamette Valley and Coast Railway Co will build an elevator here costing \$15,000. Address F C Buell, Corvallis, Ore.

WORCESTER.—Nothing of \$7,000 to report this week.

YOUNGSTOWN, O.—Nothing over \$7,000 to report, but about 20 bldgs less than \$7,000 are being erected here.

LAMAR, MO.—Our correspondent writes: "The people by special vote have authorized the County Court to levy a special tax to build Court-house, and the County Court has set the first Monday in December to select plans for Court-house."

HARRISBURG, PA.—No new work over \$7,000 in value to report this week.

LOWELL, MASS.—Dutton st, 3-story br mill; o and b, E G Baker.

Pawtucket st, addition to the Lowell Hospital; b, C H Nelson.

TILTON, N H.—A new hotel is proposed.

PORTSMOUTH, N H.—Eldredge Brewery is to have a tower 125 feet high.

NEWPORT, N H.—Apparatus for manufacturing water-gas is being put into the shoe factory.

BERLIN, N H.—The streets and stores are to be lighted by 40 arc lights.

BUFFALO, N Y.—Building to the amount of \$13,000 is going on here this week.
